There are many different opinions about the choice of Gravel; ſome are for having the Gravel as white as poſſible, and in order to make the walks more ſo, they roll them well with ſtone rollers, which are often hewn by the maſons, that they may add a whiteneſs to the walks; but this renders it very troubleſome to the eyes, by reflecting the rays of light ſo ſtrongly, therefore this ſhould ever be avoided; and ſuch Gravel as will lie ſmooth, and reflect the leaſt, ſhould be preferred.

Some ſcreen the Gravel too fine, which is an error; for if it be caſt into a round heap, and the great ſtones only raked off, it will be the better.

Some are apt to lay Gravel-walks too round, but this is likewiſe an error, becauſe they are not ſo good to walk upon, and beſides, it makes them look narrow; one inch riſe is enough in a crown for a walk of five feet; and it will be ſufficient, if a walk be ten feet wide, that it lies two inches higher in the middle than it does on each ſide; if fifteen feet, three inches; twenty feet, four; and ſo in proportion.

For the depth of Gravel-walks, ſix or eight inches may do well enough, but a foot thickneſs will be ſufficient for any; but then there ſhould always be a depth of rubbiſh laid under the Gravel, eſpecially if the ground is wet; in which caſe there cannot be too much care to fill the bottom of the walks with large ſtones, flints, brick rubbiſh, chalk, or any other materials which can be beſt procured, which will drain off the moiſture from the Gravel, and prevent its being poachy in wet weather; but as it may be difficult in ſome places to procure a ſufficient quantity of theſe materials to lay in the bottom of the walks, ſo there may be a bed of Heath, or Furze, which ever can be procured at the leaſt expence, laid under the Gravel to keep it dry: and if either of theſe are uſed green, they will lie a long time, as they will be covered from air, and theſe will prevent the Gravel from getting down into the clay, and will always keep the Gravel dry; and where there is not this precaution in the firſt laying of the Gravel upon clay, the water being detained by the clay, will cauſe the Gravel to be poachy whenever there is much rain.

In making of Gravel-walks, there muſt be great regard had to the level of the ground, ſo as to lay the walks with eaſy deſcents toward the low parts of the ground, that the wet may be drained off eaſily; for when this is omitted, the water will lie upon the walks a conſiderable time after hard rains, which will render them unfit for uſe, eſpecially when the ground is naturally wet or ſtrong; but where the ground is level, and there are no declivities to carry off the wet, it will be proper to have ſink-ſtones laid by the ſides of the walks, at convenient diſtances, to let off the wet; and where the ground is naturally dry, that the water will ſoon ſoak away, the drains of the ſink-ſtones may be contrived ſo as to convey the water in ſeſſpools, from which the water will ſoak away in a ſhort time; but in wet land there ſhould be under-ground drains, to convey the wet off, either into ponds, ditches, or the neareſt place to receive it; for where this is not well provided for, the walks will never be ſo handſome or ſo uſeful.

The month of March is the propereſt time for laying Gravel; it is not prudent to do it ſooner, or to lay walks in any of the winter months before that time.

Some indeed turn up Gravel-walks in ridges in December, in order to kill the weeds; but this is very wrong, for beſides that it deprives them of the benefit of them all the winter, it does not anſwer the end for which it is done, but rather the contrary; for though it does kill the weeds for the preſent, yet it adds a fertility to them, as to the great future increaſe of both them and Graſs.

If conſtant rolling them after the rains and froſt will not effectually kill the weeds and moſs, you ſhould turn the walks in March, and lay them down at the ſame time.

In order to deſtroy worms that ſpoil the beauty of Gravel, or Graſs-walks, ſome recommended the watering them well with water, in which Walnut-tree leaves have been ſteeped, and made very bitter, eſpecially thoſe places moſt annoyed with them; and this they ſay, as ſoon as it reaches them, will make them come out haſtily, ſo that they may be gathered; but if, in the firſt laying of the walks, there is a good bed of lime rubbiſh laid in the bottom, it is the moſt effectual method to keep out the worms, for they do not care to harbour near lime.

GREEN-HOUSE, or Conſervatory.

As of late years there have been great quantities of curious exotic plants introduced into the Engliſh gardens, ſo the number of Green-houſes, or Conſervatories, have increaſed; and not only a greater ſkill in the management and ordering of theſe plants has increaſed therewith, but alſo a greater knowledge of the ſtructure and contrivance of theſe places, ſo as to render them both uſeful and ornamental, hath been acquired; and ſince there are many particulars to be obſerved in the conſtruction of theſe houſes, whereby they will be greatly improved, I thought it neceſſary not only to give the beſt inſtructions for this I was capable of, but alſo to give a deſign of one in the manner I would chuſe to erect it, upon the annexed copper-plate.

This ſtands in the liſt of medicinal plants, but is very rarely uſed in England, though it is recommended by ſome good writers as a purger of ſerous and choleric humours.

The ſecond ſort grows naturally in North America, from whence I received the ſeeds. This grows naturally in moiſt places, where it riſes more than a foot high, but in England I have not ſeen it more than eight inches; the leaves are blunt, and indented at their extremities; the flowers are white, and come out from the ſide of the ſtalks, like thoſe of the other, but are not ſucceeded by ſeeds here. It may be propagated in the ſame manner as the firſt ſort, and requires the ſame treatment.

The ſeeds of the third ſort were ſent me from Carthagena, where it was found growing naturally in places where there had been ſtanding waters, which were then dried up; this plant grew about nine inches high, with a weak ſtalk, and the leaves placed oppoſite; they were about three quarters of an inch long, and half an inch broad, ſawed on their edges; the flowers came out ſingle on each ſide the ſtalk; they were white, and much ſmaller than thoſe of the firſt ſort, but were not ſucceeded by ſeeds, ſo the plant was loſt here.

GRAVEL and Graſs are naturally ornaments to a country-ſeat, and the glory of the Engliſh gardens, and things in which we excel all other nations, as France, Holland, Flanders, &c.

There are different ſorts of Gravel, but for thoſe who can conveniently have it, I approve of that Gravel on Blackheath, as preferable to moſt that we have in England; it conſiſts of ſmooth even pebbles, which, when mixed with a due quantity of loam, will bind exceeding cloſe, and look very beautiful, and continue handſome longer than any other ſort of Gravel which I have yet ſeen.

Some recommend a ſort of iron-mould Gravel, or Gravel with a little binding loam amongſt it, than which nothing, they ſay, binds better when it is dry; but in wet weather it is apt to ſtick to the heels of one's ſhoes, and will never appear handſome.

Sometimes loam is mixed with Gravel that is over ſandy or ſharp, which muſt be very well blended together, and let lie in heaps, after which it will bind like a rock.

There are many kinds of Gravel which do not bind, and thereby cauſe a continual trouble of rolling, to little or no purpoſe; as for ſuch,

If the Gravel be looſe or ſandy, you ſhould take one load of ſtrong loam, to two or three of Gravel, and ſo caſt them well together, and turn this mixture over three or four times, that they may be well blended together; if this is done in proper proportion, it will bind well, and not ſtick to the feet in wet weather.

There are many different opinions about the choice of Gravel; ſome are for having the Gravel as white as poſſible, and in order to make the walks more ſo, they roll them well with ſtone rollers, which are often hewn by the maſons, that they may add a whiteneſs to the walks; but this renders it very troubleſome to the eyes, by reflecting the rays of light ſo ſtrongly, therefore this ſhould ever be avoided; and ſuch Gravel as will lie ſmooth, and reflect the leaſt, ſhould be preferred.

Some ſcreen the Gravel too fine, which is an error; for if it be caſt into a round heap, and the great ſtones only raked off, it will be the better.

Some are apt to lay Gravel-walks too round, but this is likewiſe an error, becauſe they are not ſo good to walk upon, and beſides, it makes them look narrow; one inch riſe is enough in a crown for a walk of five feet; and it will be ſufficient, if a walk be ten feet wide, that it lies two inches higher in the middle than it does on each ſide; if fifteen feet, three inches; twenty feet, four; and ſo in proportion.

As for the depth of Gravel-walks, ſix or eight inches may do well enough, but a foot thickneſs will be ſufficient for any; but then there ſhould always be a depth of rubbiſh laid under the Gravel, eſpecially if the ground is wet; in which caſe there cannot be too much care to fill the bottom of the walks with large ſtones, flints, brick rubbiſh, chalk, or any other materials which can be beſt procured, which will drain off the moiſture from the Gravel, and prevent its being poachy in wet weather; but as it may be difficult in ſome places to procure a ſufficient quantity of theſe materials to lay in the bottom of the walks, ſo there may be a bed of Heath, or Furzes, which ever can be procured at the leaſt expence, laid under the Gravel to keep it dry; and if either of theſe are uſed green, they will lie a long time, as they will be covered from air, and theſe will prevent the Gravel from getting down into the clay, and will always keep the Gravel dry; and where there is not this precaution in the firſt laying of the Gravel upon clay, the water being detained by the clay, will cauſe the Gravel to be poachy whenever there is much rain.

In making of Gravel-walks, there muſt be great regard had to the level of the ground, ſo as to lay the walks with eaſy deſcents toward the low parts of the ground, that the wet may be drained off eaſily; for when this is omitted, the water will lie upon the walks a conſiderable time after hard rains, which will render them unfit for uſe, eſpecially when the ground is naturally wet or ſtrong; but where the ground is level, and there are no declivities to carry off the wet, it will be proper to have ſink-ſtones laid by the ſides of the walks, at convenient diſtances, to let off the wet; and where the ground is naturally dry, that the water will ſoon ſoak away, the drains of the ſink-ſtones may be contrived ſo as to convey the water into ſinkholes, from which the water will ſoak away in a ſhort time; but in wet land there ſhould be under-ground drains, to convey the wet off, either into ponds, ditches, or the neareſt place to receive it; for where this is not well provided for, the walks will never be ſo handſome or ſo uſeful.

The month of March is the propereſt time for laying Gravel; it is not prudent to do it ſooner, or to lay walks in any of the winter months before that time. Some indeed turn up Gravel-walks in ridges in December, in order to kill the weeds; but this is very wrong, for beſides that it deprives them of the benefit of them all the winter, it does not anſwer the end for which it is done, but rather the contrary; for though it does kill the weeds for the preſent, yet it adds a fertility to them, as to the great future increaſe of both them and Graſs.

If conſtant rolling them after the rains and froſt will not effectually kill the weeds and moſs, you ſhould turn the walks in March, and lay them down at the ſame time.

In order to deſtroy worms that ſpoil the beauty of Gravel, or Graſs-walks, ſome recommended the watering them well with water, in which Walnut-tree leaves have been ſteeped, and made very bitter, eſpecially thoſe places moſt annoyed with them; and they ſay, as ſoon as it reaches them, will make them come out haſtily, ſo that they may be gathered; but if, in the firſt laying of the walks, there is a good bed of lime rubbiſh laid in the bottom, it is the moſt effectual method to keep out the worms, for they do not care to harbour near lime.

J. Haynes Sculp.

As to the length of theſe houſes, that muſt be proportioned to the number of plants they are to contain, or the fancy of the owner; but their depth ſhould never be greater than their height in the clear, which in ſmall, or middling houſes, may be ſixteen or eighteen feet, but for large ones, from twenty to twenty-four feet, is a good proportion; for if the Green-houſe is long, and too narrow, it will have a bad appearance both within and without, nor will it contain ſo many plants, if proper room be allowed for paſſing in front, and on the backſide of the ſtands on which the plants are placed; and on the other hand, if the depth of the Green-houſe is more than twenty-four feet, there muſt be more rows of plants placed to fill the houſe, than can with conveniency be reached in watering and cleaning; nor are houſes of too great depth ſo proper for keeping of plants, as thoſe of moderate ſize.

The windows in front ſhould extend from about one foot and a half above the pavement, to within the ſame diſtance of the cieling, which will admit of a cornice round the building, over the heads of the windows. As it is neceſſary to have theſe windows ſo long, it will be impoſſible to make them in proportion as to their breadth; for if in the largeſt buildings the ſaſhes are more than ſeven, or ſeven feet and a half broad, they will be ſo heavy and troubleſome to move up and down, as to render it very difficult for one perſon to perform; beſides, their weight will occaſion their ſoon decaying. There is alſo another inconvenience in having the windows too broad, which is that of fixing proper ſhutters to them, in ſuch a manner as that they may fall back cloſe to the piers, ſo as not to be incommodious, or when open to obſtruct any part of the rays of light from reaching the plants. The piers between theſe windows ſhould be as narrow as poſſible to ſupport the building, for which reaſon I ſhould chuſe to have them of ſtone, or of hard well-burnt bricks; for if they are built with fine rubbed bricks, thoſe are generally ſo ſoft, that the piers will require to be made thicker, and the building will be leſs ſtrong, eſpecially if there are any rooms over the Green-houſe; which is what I would always adviſe, as being of great uſe to keep the froſt out in very hard winters. If theſe piers are made of ſtone, I would adviſe them to be two feet and a half in diameter, worked as columns cylindrical, whereby the rays of the ſun will not be taken off, or obſtructed by the corners of the piers, which it would be if they were ſquare; but if they are built with bricks, it will be proper to make them three feet in front, otherwiſe they will be too weak to ſupport the building; theſe I would alſo adviſe to be ſloped off toward the inſide to admit the ſun.

At the back of the Green-houſe there may be erected a houſe for tools, and for many other purpoſes, which will be extremely uſeful, and will alſo prevent the froſt from entering the houſe on the backſide, ſo that the wall between theſe need not be more than two bricks and a half in thickneſs; whereas were it quite expoſed behind, it ſhould be at leaſt three bricks, or three and a half in thickneſs; and by this contrivance, if you are willing to make a handſome building, and to have a noble room over the Green-houſe, you may make the room over the tool-houſe, and carry up the ſtair-caſe in the back, ſo as not to be ſeen in the Green-houſe, and hereby you may have a room twenty-five or thirty feet in width, and of a proportionable length; and under this ſtair-caſe there ſhould be a private door into the green-houſe, at which the gardener may enter in hard froſty weather, when it will not be ſafe to open any of the glaſſes in the front. The floor of the Green-houſe, which ſhould be laid either with Bremen ſquares, Purbeck ſtone, or broad tiles, according to the fancy of the owner, muſt be raiſed two feet above the ſurface of the ground whereon the houſe is placed, which in dry ground will be ſufficient; but if the ſituation is moiſt and ſpringy, and thereby ſubject to damps, it ſhould be raiſed at leaſt three feet above the ſurface; and if the whole is arched with low brick arches under the floor, it will be of great ſervice in preventing the damps riſing in winter, which are often very hurtful to the plants, eſpecially in great thaws; when the air is often too cold to be admitted into the houſe, to take off the damps. Under the floor, about one foot from the front, I would adviſe a flue of one foot in width, and two feet deep, to be carried the whole length of the houſe, which may be returned againſt the back wall, and carried up in proper funnels adjoining to the tool-houſe, three times over each other, by which the ſmoke may paſs off. The fire-place may be contrived at one end of the houſe, and the door at which the fuel is put in, as alſo the aſh-grate, may be contrived to open into the tool-houſe, ſo that it may be quite hid from the ſight, and be in the dry, and the fuel may be laid in the ſame ſhed, whereby it will always be ready for uſe.

I ſuppoſe many people will be ſurpriſed to ſee me direct the making of flues under a Green-houſe, which has been diſuſed ſo long, and by moſt people thought of ill conſequence, as indeed they have often proved, when under the direction of unſkilful managers, who have thought it neceſſary, whenever the weather was cold to make fires therein; but however injurious flues may have been under ſuch management, yet when ſkilfully looked after they will be found of very great ſervice; for though perhaps it may happen, that there will be no neceſſity to make any fires in them for two or three years together, as when the winters prove mild there will not, yet in very hard winters they will be extremely uſeful to keep out the froſt, which cannot be effected any other way, but with great trouble and difficulty.

Withinſide of the windows, in front of the Green-houſe, you ſhould have good ſtrong ſhutters, which ſhould be made with hinges to fold back, that they may fall back quite cloſe to the piers, that the rays of the ſun may not be obſtructed thereby. Theſe ſhutters need not be above an inch and a half thick, or little more when wrought, which if made to join cloſe, will be ſufficient to keep out our common froſt; and when the weather is ſo cold as to endanger the freezing in the houſe, it is but making a fire in the oven, which will effectually prevent it; and without this conveniency it will be very troubleſome, as I have often ſeen, where perſons have been obliged to nail mats before their windows, or to ſtuff the hollow ſpace between the ſhutters, and the glaſs with Straw, which when done, is commonly ſuffered to remain till the froſt goes away; which if it ſhould continue very long, the keeping the Green-houſe cloſely ſhut up, will prove very injurious to the plants; and as it frequently happens, that we have an hour or two of the ſun-ſhine in the middle of the day, in continued froſts, which is of great ſervice to plants, when they can enjoy the rays thereof through the glaſſes, ſo when there is nothing more to do than to open the ſhutters, which may be performed in a very ſhort time, and as ſoon ſhut again when the ſun is clouded, the plants may have the benefit thereof whenever it appears; whereas, where there is ſo much trouble to uncover, and as much to cover again, it would take up the whole time in uncovering and ſhutting them up, and thereby the advantage of the ſun's influence would be loſt. Beſides, where there is ſo much trouble required to keep out the froſt, it will be a great chance if it be not neglected by the gardener; for if he be not as fond of preſerving his plants, and as much in love with them as his maſter, this labour will be thought too great by him; and if he takes the pains to cover the glaſſes up with mats, &c. he will not care to take them away again until the weather alters, ſo that the plants will be ſhut up cloſe during the whole continuance of the froſt.

There are ſome people who commonly make uſe of pots filled with charcoal to ſet in their Green-houſe in very ſevere froſts, but this is very dangerous to the perſons who attend theſe fires, and I have ſometimes known they have been almoſt ſuffocated therewith, and at the ſame time they are very injurious to the plants; nor is the trouble of tending upon theſe ſmall, and the many hazards to which the uſe of theſe fires is liable, have juſtly brought them into diſuſe with all ſkilful perſons; and as the contrivances of flues, and of the fires, are but ſmall charges in their firſt erecting, they are much to be preferred to any other method for warming the air of the houſe.

The wall on the back part of the houſe ſhould be either laid over with ſtucco, or plaſtered with mortar, and white-waſhed, for otherwiſe the air in ſevere froſt will penetrate through the walls, eſpecially when the froſt is attended with a ſtrong wind, which is often the caſe in moſt ſevere winters. There are ſome perſons who are at the expence of wainſcotting their Green-houſes, but when this is done, it is proper to plaſter the walls with lime and hair behind the wainſcot, to keep out the cold; and when they are lined with wainſcot, they ſhould be painted white, as ſhould the cieling, and every part withinſide of the houſe; for this reflects the rays of light in a much greater quantity than any other colour, and is of ſignal ſervice to plants, eſpecially in the winter, when the houſe is pretty much cloſed, and but a ſmall ſhare of light is admitted through the windows; for at ſuch times I have obſerved, that in ſome Green-houſes which have been painted black, or of a dark colour, the plants have caſt moſt of their leaves.

Where green-houſes are built in ſuch places as will not admit of rooms over them, or the perſon is unwilling to be at the expence of ſuch buildings, there muſt be care taken to keep out the froſt from entering through the roof. To prevent which it will be very proper to have a thickneſs of Reeds, Heath, or Eurz, laid between the cieling and the tiles; in the doing of which there muſt be care taken in framing the joiſts, ſo as to ſupport theſe, that their weight may not lie upon the ceiling, which might endanger it; for theſe ſhould be laid a foot thick at leaſt, and as ſmooth as poſſible, and faſtened down well with laths to prevent their riſing, and then covered over with a coat of lime and hair, which will keep out the air, and alſo prevent mice and other vermin from harbouring in them, which, if left uncovered, they would certainly do. For want of this precaution there are many Green-houſes built, which will not keep out the froſt in hard winters, and this is many times attributed to the glaſſes in front admitting the cold, when the fault is in the roof; for where there is only the covering, either of tiles or ſlates, over the cieling, every ſevere froſt will penetrate through them.

In this Green-houſe you ſhould have truſſels, which may be moved out and into the houſe, upon which you ſhould fix rows of planks, ſo as to place the pots or tubs of plants in regular rows one above another, whereby the heads of the plants may be ſo ſituated, as not to interfere with each other. The loweſt row of plants, which ſhould be the forwardeſt towards the windows, ſhould be placed about four feet therefrom, that there may be a convenient breadth left next the glaſſes to walk in front; and the rows of plants ſhould riſe gradually from the firſt, in ſuch a manner that the heads of the ſecond row ſhould be entirely advanced above the firſt, the ſtems only being hid thereby; and at the back ſide of the houſe there ſhould be allowed a ſpace of at leaſt five feet, for the conveniency of watering the plants, as alſo to admit of a current of air round them, that the damps occaſioned by the perſpiration of the plants, may be the better diſſipated, which, by being pent in too cloſely, often occaſions a mouldineſs upon the tender ſhoots and leaves, and when the houſe is cloſe ſhut up, this ſtagnating rancid vapour is often very deſtructive to the plants; for which reaſon alſo you ſhould never croud them too cloſe to each other, nor ſhould you ever place Sedums, Euphorbiums, Torch Thiſtles, and other tender ſucculent plants, amongſt Oranges, Myrtles, and other Evergreen trees; for, by an experiment which I made, anno 1729, I found that a Sedum placed in a Green-houſe among ſuch trees, almoſt daily increaſed its weight, although there was no water given to it the whole time; which increaſe of weight was owing to the moiſture imbibed from the air, which, being replete with the rancid vapours perſpired from the other plants, occaſioned the leaves to grow pale, and in a ſhort time they decayed and dropped off; which I have often obſerved has been the caſe with many other ſucculent plants, when placed in thoſe houſes which were filled with many ſorts of Evergreen trees, that required to be frequently watered.

Therefore, to avoid the inconvenience which attends the placing of plants of very different natures in the ſame houſe, it will be very proper to have two wings added to the main Green-houſe, which, if placed in the manner expreſſed in the annexed plan, will greatly add to the beauty of the building, and alſo collect a greater ſhare of heat. In this plan the Green-houſe is placed exactly fronting the ſouth, and one of the wings faces the ſouth-eaſt, and the other the ſouth-weſt; ſo that from the time of the ſun's firſt appearance upon any part of the building, until it goes off at night, it is conſtantly reflected from one part to the other, and the cold winds are alſo kept off from the front of the main Green-houſe hereby; and in the area of this place you may contrive to place many of the moſt tender exotic plants, which will bear to be expoſed in the ſummer ſeaſon; and in the ſpring, before the weather will permit you to ſet out the plants, the beds and borders of this area may be full of Anemonies, Ranunculuſes, early Tulips, &c. which will be paſt flowering, and the roots fit to take out of the ground by the time you carry out the plants, which will render this place very agreeable during the ſpring ſeaſon, when the flowers are blown: and here you may walk and divert yourſelf in a fine day, when perhaps the air in moſt other parts of the garden will be too cold for perſons not much uſed thereto, to take pleaſure in being out of the houſe.

In the center of this area may be contrived a ſmall baſon for water, which will be very convenient for watering of plants, and add much to the beauty of the place; beſides the water being thus ſituated, will be ſoftened by the heat which will be reflected from the glaſſes upon it, whereby it will be rendered much better than raw cold water for theſe tender plants.

The two wings of the building ſhould be contrived ſo as to maintain plants of differing degrees of hardineſs, which muſt be effected by the ſituation and extent of the fire-place, and the manner of conducting the flues, a particular account of which will be exhibited under the article of Stoves. But I would here obſerve, that the wing facing the ſouth-eaſt ſhould always be preferred for the warmeſt ſtove, its ſituation being ſuch, as that the ſun, upon its firſt appearance in the morning, ſhines directly upon the glaſſes, which is of great ſervice in warming the air of the houſe, and adding life to the plants, after having been ſhut up during the long nights in the winter ſeaſon. Theſe wings being in the draught annexed, allowed ſixty feet in length, may be divided in the middle by partitions of glaſs, with glaſs-doors to paſs from one to the other. To each of theſe there ſhould be a fire-place, with flues carried up againſt the back wall, through which the ſmoke ſhould be made to paſs, as many times the length of the houſe, as the height will admit of the number of flues; for the longer the ſmoke is in paſſing, the more heat will be given to the houſe, with a leſs quantity of fuel, which is an article worth conſideration, eſpecially where fuel is dear. By this contrivance you may keep ſuch plants as require the ſame degree of heat in one part of the houſe, and thoſe which will thrive in a much leſs warmth in the other part, but this will be more fully explained under the article of Stoves.

The other wing of the houſe, facing the ſouth-weſt, may alſo be divided in the ſame manner, and flues carried through both parts, which may be uſed according to the ſeaſons, or the particular ſorts of plants which are placed therein; ſo that here will be four diviſions in the wings, each of which may be kept up to a different degree of warmth, which, together with the Green-houſe, will be ſufficient to maintain plants from all the ſeveral countries of the world; and without having theſe ſeveral degrees of warmth, it will be impoſſible to preſerve the various kinds of plants from the ſeveral parts of Africa and America, which are annually introduced into the Engliſh gardens; for when plants from different countries are placed in the ſame houſe, ſome are deſtroyed for want of heat, while others are forced and ſpoiled by too much of it; and this is often the caſe in many places, where there are large collections of plants.

In the building theſe wings, if there are not ſheds running behind them their whole length, the walls ſhould not be leſs than three bricks thick; and if they are more, it will be better, becauſe where the walls are thin, and expoſed to the open air, the cold will penetrate them, and when the fires are made, the heat will come out through the walls, ſo that it will require a larger quantity of fuel, to maintain a proper temperature of warmth in the houſe. The back part of theſe houſes having ſloping roofs, which are covered either with tiles or ſlates, ſhould alſo be lined with Reeds, &c. under the covering, as is before directed for the Green-houſe, which will keep out the cold air, and ſave a great expence of fuel; for the cloſer and better theſe houſes are built, and the glaſſes of the ſlope, as alſo in front, well guarded by ſhutters, or Reeds in hard froſt, the leſs fuel will be required to warm the houſes; ſo that the firſt expence in building theſe houſes properly, will be the cheapeſt, when the after-expence of fires is taken into conſideration.

The ſloping glaſſes of theſe houſes ſhould be made to ſlide and take off, ſo that they may be drawn down more or leſs in warm weather, to admit air to the plants; and the upright glaſſes in front may be ſo contrived, as that every other may open as doors upon hinges, and the alternate glaſſes may be divided into two; the upper part of each ſhould be contrived ſo as to be drawn down like ſaſhes, ſo that either of theſe may be uſed to admit air, in a greater or leſs proportion, according as there may be occaſion.

But beſides the Conſervatories here mentioned, it will be proper to have a deep hot-bed frame, ſuch as is commonly uſed to raiſe large annuals in the ſpring, into which may be ſet pots of ſuch plants as come from Carolina, Virginia, &c. while the plants are too ſmall to plant in the open air, as alſo many other ſorts from Spain, &c. which require only to be ſcreened from the violence of froſts, and ſhould have as much free air as poſſible in mild weather; which can be no better effected than in one of theſe frames, where the glaſſes may be taken off every day when the weather will permit, and put on every night; and in hard froſts the glaſſes may be covered with mats, Straw, Peas-haulm, or the like, ſo as to prevent the froſt from entering to the pots to freeze the roots of the plants, which is what will many times utterly deſtroy them, though a ſlight froſt pinching the leaves or ſhoots, very ſeldom does them much harm; if theſe pits are ſunk a foot or more, below the ſurface of the ground, they will be the better, provided the ground is dry, otherwiſe they muſt be wholly above ground; the ſides of this frame ſhould be built with brick, with a curb of wood laid round on the top of the wall, into which the gutters, on which the glaſſes ſlide may be laid; the back wall of this frame may be four feet high, and two bricks and a half thick, the front one foot and a half; the width of the inſide of the frame about ſix feet, and the length in proportion to the number of plants to be containd therein.

GREWIA. Lin. Gen. Plant. 914. This genus of plants was conſtituted by Dr. Linnæus, who gave it this name in honour of Dr. Grew, F. R. S. who publiſhed a curious book of the anatomy of plants.

The CHARACTERS are,

The flower hath a thick leathery empalement, compoſed of five ſpear-ſhaped leaves, which are coloured, and ſpread open. The flower hath five petals of the ſame form, but ſmaller, and are indented at their baſe, where is ſituated a ſcaly nectarium to each petal, which is thick and incurved, inclining to the border, to which the ſtyle is fixed; it hath many ſtamina, which are briſtly, the length of the petals, terminated by roundiſh ſummits. In the center is ſituated the roundiſh germen, which is lengthened to a column, ſupporting a ſlender ſtyle, crowned by a four-cornered obtuſe ſtigma. The germen afterward becomes a four-cornered berry with four cells, each incloſing one globular ſeed.

This genus of plants is ranged in the ſeventh ſection of Linnæus's twentieth claſs, which includes thoſe plants whoſe flowers have many ſtamina joined to the ſtyle, forming a column of one body.

The SPECIES are,

1. GREWIA (*Occidentalis*) foliis ſubovatis crenatis. *Grewia with oval crenated leaves.* Ulmi facie arbuſcula Æthiopica, ramulis alatis, floribus purpuraſcentibus. Hort. Amſt. 1. p. 165. tab. 85. *Ethiopian Shrub with the appearance of Elm, winged branches, and purpliſh flowers.*
2. GREWIA (*Africanus*) foliis ovato-lanceolatis ſerratis. *Grewia with oval ſpear-ſhaped leaves which are ſawed.*

The firſt ſort has been long preſerved in many curious gardens, both in England and Holland, and is figured by Dr. Plukenet, by the title of Ulmifolia arbor Africana baccifera, floribus purpureis; but by Dr. Boerhaave it was ſuppoſed to be one of Father Plumier's American plants, intitled Guidonia Ulmi foliis, flore roſeo; but the characters of this do not at all agree with thoſe of the Guidonia, that particular ſpecies of this genus being in the royal garden at Paris, which is extremely different from this. It grows naturally at the Cape of Good Hope, from whence I have received the ſeeds, which have ſucceeded in the Chelſea garden.

This will grow to the height of ten or twelve feet, and has a ſtem and branches very like thoſe of the ſmall-leaved Elm, the bark being ſmooth, and of the ſame colour as that of Elm when young; the leaves are alſo very like thoſe of the Elm, and fall off in winter; the flowers are produced ſingly along the young branches from the wings of the leaves, which are of a bright purple colour; theſe appear toward the end of July, and continue in Auguſt, and the beginning of September, but are never ſucceeded by fruit in this country.

This may be propagated from cuttings or layers; the cuttings ſhould be taken off, and planted in April, before the buds ſwell, for they do not ſucceed well after; theſe cuttings ſhould be planted in ſmall pots filled with loamy earth, and the pots ſhould be plunged into a moderate hot-bed of tanners bark, where, if they are duly watered, and in the heat of the day ſhaded from the ſun, they will take good root in about two months, and may then be gradually inured to bear the open air, into which they ſhould be removed in June, and placed in a ſheltered ſituation, where they may remain till autumn, when they muſt be removed into the green-houſe; the beſt time to lay down the layers of this plant is in the ſpring, before the buds come out, and theſe will be rooted by the ſame time the following year, when they may be cut off from the old plants, and planted each into a ſeparate pot filled with a ſoft loamy ſoil.

The beſt time to remove or tranſplant this plant is, either in the ſpring, juſt before the buds begin to ſwell, or in autumn, when the leaves begin to drop; for in ſummer, when the plants are in full leaf, it will be very improper to diſturb them.

In winter theſe plants ſhould be placed in the green-houſe, for they are too tender to live abroad in England; but they ſhould have as much free air as poſſible in mild weather, for they only require to be protected from froſt, and after their leaves are fallen, they will require very moderate watering; but in ſummer they ſhould be conſtantly watered three or four times a week in dry weather, and placed in a ſheltered ſituation, with other hardy green-houſe plants, where they will add to the variety.

The ſeeds of the ſecond ſort were ſent me by Monſ. Richard, gardener to the King of France at Marſeilles,

ſeilles, which were brought from Senegal in Africa, by Monſ. Adanſon; this riſes in this country with a ſhrubby ſtalk five or ſix feet high, ſending out many lateral branches, which are covered with a brown hairy bark, and garniſhed with oval ſpear-ſhaped leaves, about two inches long, and one inch and a quarter broad in the middle, having ſeveral tranſverſe veins from the midrib to the ſides, where they are ſawed; theſe are placed alternately on the branches, having very ſhort foot-ſtalks, and continue in verdure through the year; the plants are young, ſo have not as yet flowered in England, therefore I can give no further account of them.

This ſort is tender, ſo will not live through the winter in England, unleſs it is placed in a warm ſtove; nor do thoſe plants thrive well, which are placed on ſhelves in the dry ſtove; therefore the only method to have them ſucceed, is to place them in the bark-bed in the tan-ſtove, where the plants have grown very well for ſome years. In ſummer theſe plants require a good ſhare of free air to be admitted to them, and ſhould have water three or four times a week in warm weather; but in winter they muſt be ſparingly watered, and require to be kept warm.

GRIAS. Lin. Gen. 659. Anchovy Pear.

The Characters are,

The empalement is cup-ſhaped, of one leaf, cut into four equal ſegments; the flower has four leathery concave petals, and many briſtly ſtamina which are inſerted to the receptacle, terminated by roundiſh ſummits, and a depreſſed germen immerſed in the empalement, having no ſtyle, crowned by a four-cornered croſs-ſhaped ſtigma, which afterward becomes a fleſhy berry, with a large nut having eight furrows, and one cell containing a large pointed ſeed.

This genus of plants is ranged in the firſt order of Linnæus's thirteenth claſs, intitled Polyandria Monogynia, the flower having many ſtamina and one ſtyle.

We know but one Species of this genus, viz.

1. Grias (*Cauliflora*). Lin. Sp. 732. *Anchovy Pear.* Palmis affinis malus Perſica maxima, caudice non ramoſa, foliis longiſſimis, flore tetrapetalo pallide luteo, fructu ex arboris trunco prodeunte. Sloan. Hiſt. Jam. 2. p. 122.

This plant grows naturally in Jamaica, and in many other warm parts of America, where it riſes with a ſtrait undivided ſtem about twenty feet high, having a gray bark, marked with the veſtigia of the fallen leaves; the top of the ſtem is garniſhed with leaves near two feet long and ſix inches broad, ſitting cloſe without foot-ſtalks; theſe have one longitudinal midrib with ſeveral tranſverſe veins, and are of a lucid green; the flowers come out from the ſtem below the leaves, having no foot-ſtalk, in ſome places one, and in others they are in cluſters, each having four thick yellow petals, and a great number of ſtamina which are fixed to the empalement of the flower; the germen is included in the empalement, which afterward becomes a large oval Plumb, including a large pointed nut.

The fruit of this tree is by the Spaniards in the Weſt-Indies pickled and ſent to old Spain as preſents, who eat them as Mango's, and ſome ſay the ripe fruit is eaten as a deſart.

The plant is propagated by planting of the ſtones, which ſhould be put into the ground ſoon after the fruit is gathered, and the plants muſt be conſtantly kept in the bark-bed in the ſtove, otherwiſe it will not thrive in this country.

GRONOVIA. Martyn. Cent. 4. Lin. Gen. Plant. 284. The name of this genus was given by the late Dr. Houſton, in honour of Dr. Gronovius, a learned botaniſt at Leyden.

The Characters are,

The flower hath a permanent empalement of one leaf, which is coloured, and cut to the middle into five ſegments. It hath five ſmall petals which are fixed to the cuts of the empalement, and five hairy ſtamina the length of the petals, which are inſerted into the empalement, and are placed alternate with the petals, terminated by twin ſummits which are erect. The germen is ſituated under the flower, ſupporting a ſlender ſtyle which is longer than the ſtamina, crowned by an obtuſe ſtigma. The germen afterward becomes a roundiſh-coloured fruit with one cell, incloſing one large roundiſh ſeed.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, which includes thoſe plants whoſe flowers have five ſtamina and one ſtyle.

We know but one Species of this genus, viz.

Gronovia (*Scandens*). Hort. Cliff. 74. Gronovia ſcandens lappacea, pampinea fronde. Houſt. *Climbing burry Gronovia.*

This plant was diſcovered by the late Dr. Houſtoun at La Vera Cruz, from whence he ſent the ſeeds to Europe, which have ſucceeded in many gardens. It is an annual plant, which ſends forth many trailing branches like thoſe of the Cucumber, which are cloſely ſet with broad green leaves, in ſhape like thoſe of the Vine; but they are covered with ſmall ſpines on both ſides, which ſting like the Nettle: the branches have many tendrils or claſpers, by which they faſten themſelves to whatever plants they grow near, and will riſe to the height of ſix or eight feet; the flowers are ſmall, and of a greeniſh yellow colour, ſo make no great appearance.

This being a very tender plant, muſt be raiſed on a hot-bed early in the ſpring, and afterward placed in the bark-ſtove, and treated in the ſame way as the Momordica, with which management it will produce ripe ſeeds; but this having neither uſe or beauty, is rarely cultivated but in botanic gardens for the ſake of variety.

GROSSULARIA. Raii Meth. Plant. 145. Tourn. Inſt. R. H. 639. tab. 409. Ribes. Lin. Gen. Plant. 247. Gooſeberry; in French, *Groſelier.*

This and the Currant are by Tournefort placed in the ſame genus, under the title of Groſſularia; they are alſo joined together by Dr. Linnæus, under the title of Ribes, for in their principal characters they agree; ſo according to the ſyſtems of botany, they ſhould be included in the ſame genus; but this may not be quite ſo proper in a body of gardening, for as theſe fruits have always paſſed under different denominations, ſo if they are here joined together, it may occaſion ſome confuſion among thoſe who do not enter into the ſtudy of botany. Mr. Ray has ſeparated theſe into different genera, and makes the difference of Gooſeberry from the Currant, to conſiſt in the firſt having thorns on the branches, and the fruit growing ſingle; whereas the latter hath ſmooth branches, and the fruit growing in long bunches; and although theſe differences may not be ſtrictly ſcientific, yet it may be allowed ſufficient to diſtinguiſh them among gardeners.

The Characters are,

The flower has a permanent empalement of one leaf, cut into five ſegments at the top, which is ſwollen, concave, and coloured. It hath five ſmall, obtuſe, erect petals, which riſe from the border of the empalement; and five awl-ſhaped ſtamina, which are inſerted into the empalement, terminated by compreſſed proſtrate ſummits. The germen is ſituated below the flower, having a bifid ſtyle crowned by an obtuſe ſtigma, and afterward becomes a globular berry having a navel, with one cell, which is filled with roundiſh compreſſed ſeeds included in a pulp.

This genus of plants is ranged by Dr. Linnæus in the firſt ſection of his fifth claſs, intitled Pentandria Monogynia, which contains thoſe plants whoſe flowers have five ſtamina and one ſtyle.

The Species are,

1. Grossularia (*Reclinatum*) ramis reclinatis aculeatis, pedunculis triphyllis. *Gooſeberry with reclining branches armed with ſpines, and a three-leaved foot-ſtalk.* Groſſularia ſpinoſa, fructu obſcure purpuraſcente. J. B. 1. 48. *Prickly Gooſeberry with a dark purpliſh fruit.*
2. Grossularia (*Hirſuta*) ramis aculeatis, baccis hirſutis. *Gooſeberry with prickly branches and hairy berries.* Groſſularia fructu maximo hiſpido margaritarum ferè colore. Raii Hiſt. 1484. *Gooſeberry with a very large rough fruit, almoſt of a pearl colour.*

3. GROSSULARIA (*Uva Criſpa*) ramis aculeatis, erectis, baccis glabris. *Gooſeberry with erect prickly branches, and ſmooth berries.* Groſſularia ſimplici acino, vel ſpinoſa ſylveſtris. C. B. P. 455. *Gooſeberry with a ſingle fruit, or wild prickly Gooſeberry.*

4. GROSSULARIA (*Oxyacanthoides*) ramis undique aculeatis. *Gooſeberry whoſe branches are armed on all ſides with ſpines.* Groſſularia oxyacanthæ foliis amplioribus è ſinu Hudſonis. Pluk. Amalth. 212. *Gooſeberry with larger Hawthorn leaves from Hudſon's Bay.*

5. GROSSULARIA (*Cynoſbati*) aculeis ſubaxillaribus, baccis aculeatis racemoſis. *Gooſeberry with ſpines on the lower part of the branches, and prickly berries growing in cluſters.* Ribes aculeis ſubaxillaribus, baccis aculeatis racemoſis. Lin. Sp. Plant. 202. *Currant with ſpines on the lower part of the branches, and prickly berries growing in bunches.*

The ſorts which are here enumerated, are ſuppoſed to be diſtinct ſpecies; but there are ſeveral other varieties which have been obtained from ſeeds, and are propagated for ſale in the nurſeries; moſt of theſe are titled from the perſons who raiſed them, as Lamb's Gooſeberry, Hunt's Gooſeberry, Edwards's Gooſeberry, &c. and as there are frequently new varieties obtained, it is needleſs to enumerate them here, therefore I ſhall proceed to their culture.

Theſe are propagated either by ſuckers taken from the old plants, or by cuttings; the latter of which I prefer to the former, becauſe thoſe plants which are produced from ſuckers are always more diſpoſed to ſhoot out a greater number of ſuckers from their roots, than ſuch as are raiſed from cuttings, which generally form much better roots.

The beſt ſeaſon for planting theſe cuttings is in autumn, juſt before their leaves begin to fall; obſerving always to take the handſomeſt ſhoots, and from ſuch branches as generally produce the greateſt quantity of fruit; for if you take thoſe which are produced from the ſtem of the old plants (which are commonly very luxuriant) they will not be near ſo fruitful as thoſe taken from bearing branches: theſe cuttings ſhould be about ſix or eight inches long, and muſt be planted in a border of light earth, expoſed to the morning ſun, about three inches deep, obſerving to water them gently when the weather proves dry, to facilitate their taking root; and in the ſummer, when they have put out branches, you ſhould rub off all the under ſhoots, leaving only the uppermoſt or ſtrongeſt, which ſhould be trained upright, to form a regular ſtem. In October following theſe plants may be removed; at which time you ſhould prepare an open ſpot of freſh earth, which ſhould be well dug, and cleanſed from all noxious weeds, roots, &c. and being levelled, you ſhould proceed to take up your plants, trimming their roots, and cutting off all lateral ſide branches; then plant them at three feet diſtance row from row, and one foot aſunder in the rows, obſerving to place ſome ſhort ſticks to the plants, in order to train their ſtems upright and regular. In this place they may remain one or two years, being careful to keep them clear from weeds, as alſo to trim off all lateral ſhoots which are produced below the head of the plant, ſo that the ſtem may be clear about a foot in height above the ſurface of the earth, which will be full enough; and as the branches are produced commonly very irregular in the head, you muſt cut out ſuch of them as croſs each other, or thin them where they are too cloſe, whereby the head of the plant will be open, and capable of admitting the air freely into the middle, which is of great uſe to all kinds of fruits.

After theſe plants have remained in this nurſery one or two years at moſt, they will be fit to tranſplant to the places where they are deſigned to remain; for it is not ſo well to let them grow in the nurſeries too large which will occaſion their roots to be woody, whereby the removing of them will not only hazard the growth of the plants, but ſuch of them as may take very well will remain ſtined for two or three years, before they will be able to recover their check. The ſoil in which theſe plants thrive to the greateſt advantage, is a rich light earth; though they will do very well upon middling ſoils, which are not too ſtrong or moiſt, and in all ſituations; but where the fruit is cultivated, in order to procure it in the greateſt perfection, they ſhould never be planted in the ſhade of other trees, but muſt have a free open expoſure. The diſtance they ought to be planted is eight feet row from row, and ſix feet aſunder in the rows. The beſt ſeaſon for tranſplanting them is in October, when their leaves begin to decay; obſerving, as was before directed, to prune their roots, and trim off all lateral ſhoots, or ſuch as croſs each other, ſhortening all long branches, ſo as to make the head regular.

In the pruning of theſe ſhrubs moſt people make uſe of garden-ſhears, obſerving only to cut the head round, as is practiſed for Evergreens, &c. whereby the branches become ſo much crowded, that what fruit is produced, never grows to half the ſize as it would do were the branches thinned, and pruned according to art; which ſhould always be done with a pruning-knife, ſhortening the ſtrong ſhoots to about ten inches, and cutting out all thoſe which grow irregular, thinning the fruit-bearing branches where they are too thick, obſerving always to cut behind a leaf bud. With this management your fruit will be near twice as large as thoſe which are produced upon ſuch buſhes as are not thus pruned, and the ſhrubs will continue in vigour much longer; but you muſt obſerve to keep the ground clear from weeds, and dig it at leaſt once a year; and every other year you ſhould beſtow a little rotten dung upon it, which will greatly improve the fruit.

It is a common practice with the gardeners near London, who have great quantities of theſe buſhes in order to ſupply the markets, to prune them ſoon after Michaelmas, and then to dig up the ground between the rows, and plant it with Coleworts for ſpring uſe, whereby their ground is employed all the winter, without prejudicing the Gooſeberries; and in hard winters theſe Coleworts often eſcape, when thoſe which are planted in an open expoſure are all deſtroyed; and theſe are generally pulled up for uſe in February or March, ſo that the ground is clear before the Gooſeberries come out in the ſpring; which is a piece of huſbandry well worth practiſing where ground is dear, or where perſons are confined for room.

GROVES are the greateſt ornaments to a garden, nor can a garden be complete which has not one or more of theſe. In ſmall gardens there is ſcarce room to admit of Groves of any extent, yet in theſe there ſhould be at leaſt one contrived, which ſhould be as large as the ground will allow it; and where theſe are ſmall, there is more ſkill required in the diſpoſition, to give them the appearance of being larger than they really are.

Groves have been in all ages held in great veneration: the ancient Romans had a ſort of Groves near ſeveral of their temples, which were conſecrated to ſome God, and were called luci by antiphraſis, à non lucendo, as being ſhady and dark; and theſe were dedicated to holy uſes, being places of ſolitude and retirement, and were never to be violated with the ax.

Theſe Groves are not only great ornaments to gardens, but are alſo the greateſt relief againſt the violent heats of the ſun, affording ſhade to walk under in the hotteſt part of the day, when the other parts of the garden are uſeleſs; ſo that every garden is defective which has not ſhade.

Groves are of two ſorts, viz. open and cloſe Groves: open Groves are ſuch as have large ſhady trees, which ſtand at ſuch diſtances, as that their branches may approach ſo near each other, as to prevent the rays of the ſun from penetrating through them; but as ſuch trees are a long time in growing to a proper ſize for affording a ſhade, ſo where new Groves are planted, the trees muſt be placed cloſer together, in order to have ſhade as ſoon as poſſible; but in planting of theſe Groves, it is much the beſt way to diſpoſe all the trees irregularly, which will give them a greater magnificence, and alſo form a ſhade ſooner, than when the trees are planted in lines; for when the ſun ſhines between the rows of trees, as it muſt do ſome part of the day in ſummer, the walks between them will be expoſed to the heat at ſuch times, until the branches of theſe trees meet; whereas in the irregular plantations, the trees intervene, and obſtruct the direct rays of the ſun.

When a perſon who is to lay out a garden, is ſo happy as to meet with large full grown trees upon the ſpot, they ſhould remain inviolate, if poſſible; for it will be better to put up with many inconveniencies, than to deſtroy theſe, which will require an age to retrieve; ſo that nothing but that of offending the habitation, by being ſo near as to occaſion great damps or obſtructing fine views, ſhould tempt the cutting of them down.

Moſt of the Groves which have been planted either in England, or in thoſe celebrated gardens of France, are only a few regular lines of trees; many of which are avenues to the habitation, or lead to ſome building, or object; but theſe do not appear ſo grand, as thoſe which have been made in woods where the trees have grown accidentally, and at irregular diſtances; and where the trees have large ſpreading heads, and are left at ſuch a diſtance, as to permit the Graſs to grow under them, then they afford the greateſt pleaſure: for nothing is more noble than fine ſpreading trees with large ſtems, growing through Graſs, eſpecially if the Graſs is well kept, and has a good verdure; beſides, moſt of theſe planted Groves have generally a gravel-walk, made in a ſtrait line between them, which greatly offends the ſight of perſons who have true taſte; therefore whenever a gravel-walk is abſolutely neceſſary to be carried through theſe Groves, it will be much better to twiſt it about, according as the trees naturally ſtand, than to attempt regularity; but dry walks under large trees are not ſo uſeful as in open places, becauſe the dropping of the trees will render theſe walks uſeleſs after rain, for a conſiderable time.

Cloſe Groves have frequently large trees ſtanding in them, but the ground is filled under theſe with ſhrubs, or under-wood; ſo that the walks which are made in them are private, and ſcreened from winds, whereby they are rendered agreeable for walking, at ſuch times when the air is too violent or cold for walking in the more expoſed parts of the garden.

Theſe are often contrived ſo as to bound the open Groves, and frequently to hide the walls, or other incloſures of the garden; and when they are properly laid out, with dry walks winding through them, and on the ſides of theſe ſweet-ſmelling ſhrubs and flowers irregularly planted, they have a charming effect; for here a perſon may walk in private, ſheltered from the inclemency of cold or violent winds, and enjoy the greater ſweets of the vegetable kingdom: therefore where it can be admitted, if they are continued round the whole incloſure of the garden, there will be a much greater extent of walk; and theſe ſhrubs will appear the beſt boundary, when there are not fine proſpects to be gained.

Theſe cloſe Groves are by the French termed boſquets, from the Italian word boſquetto, which ſignifies a little wood, and in moſt of the French gardens there are many of them planted; but theſe are reduced to regular figures, as ovals, triangles, ſquares, and ſtars; which have neither the beauty or uſe which thoſe have that are made irregularly, and whoſe walks are not ſhut up on each ſide by hedges, which prevents the eye from ſeeing the quarters; and theſe want the fragancy of the ſhrubs and flowers, which are the great delight of theſe private walks: add to this, the keeping of the hedges in good order is attended with a great expence, which is a capital thing to be conſidered in the making of gardens.

GUAIABARA. See Coccolobos.

GUAJACANA. See Diospyros.

GUAJACUM. Plum. Nov. Gen. 39. tab. 17. Lin. Gen. Plant. 465. Lignum Vitæ, or Pockwood.

The Characters are,

The flower hath a concave empalement of one leaf, which is quinquefid. It hath five oblong, oval, concave petals, which are inſerted in the empalement and ſpread open, and ten erect ſtamina inſerted in the empalement, terminated by ſmall ſummits. The ſtyle is long and ſlender, the germen is oval and pointed, and the ſtigma is ſingle and ſlender. The germen afterward becomes a berry which is roundiſh, with an oblique point, and deeply furrowed, incloſing an oval hard ſeed.

This genus of plants is ranged in the firſt ſection of Linnæus's tenth claſs, intitled Decandria Monogynia, which includes thoſe plants whoſe flowers have ten ſtamina and one ſtyle.

The Species are,

1. Guajacum (*Officinale*) foliolis bijugatis obtuſis. Lin. Sp. Plant. 381. *Guajacum with obtuſe lobes placed by pairs.* Guajacum flore cæruleo, fructu ſubrotundo. Plum. Nov. Gen. 391. *Guajacum with a blue flower and a roundiſh fruit.*
2. Guajacum (*Sanctum*) foliolis multijugatis obtuſis. Lin. Sp. Plant. 382. *Guajacum with many pair of obtuſe lobes.* Guajacum flore cæruleo fimbriato, fructu tetragono. Plum. Nov. Gen. 391. *Guajacum with a blue fringed flower, and a four-cornered fruit.*
3. Guajacum (*Afrum*) foliolis multijugatis obtuſis. Lin. Sp. Plant. 382. *Guajacum with many pair of acute-pointed lobes.* Guilandinoides. Hort. Cliff. 489. and the Afra arbor acaciæ ſimilis, foliis myrti aculeatis ſplendentibus. Boerh. Ind. alt. 2. p. 57. *African-tree like the Acacia, with ſhining, acute-pointed, Myrtle leaves.*

The firſt ſort is the common Lignum Vitæ, or Guajacum, which is uſed in medicine, and grows naturally in moſt of the iſlands in the Weſt-Indies, where it riſes to be a very large tree, having a hard, brittle, browniſh bark, not very thick; the wood is firm, ſolid, and ponderous, appearing very reſinous, of a blackiſh yellow colour within, and of a hot aromatic taſte; the ſmaller branches have an Aſh-coloured bark, garniſhed with leaves, which are divided by pairs, each pair having two pair of ſmall, oval, blunt leaves (or pinnæ) of a ſtiff conſiſtence, and a lucid green; the flowers are produced in cluſters at the end of the branches, compoſed of five oval concave petals, of a fine blue colour; in the center of theſe is fixed a ſtyle with an oval germen, crowned by a ſlender ſtigma; and round this is ſituated from ten to twenty ſtamina, which are as long as the ſtyle, terminated by ſickle-ſhaped ſummits. Dr. Linnæus ſuppoſes the flowers to have but ten ſtamina, whereas they certainly have near twenty.

The bark and wood of this tree are much of the ſame nature, only the wood is accounted hotter; they are uſed in diet-drinks to purify and cleanſe the blood, and to cauſe ſweating; they are eſteemed good for the gout and dropſy, the king's-evil, and particularly for the French pox. The gum or reſin, which is black, ſhining, and brittle, and when powdered, of a greeniſh white colour, of an aromatic ſmell, and poignant taſte, is ſomewhat cathartic, and a good purge in rheumatic caſes, to the quantity of two ſcruples mixed with the yolk of an egg, and given in a convenient vehicle.

The wood of this tree is ſo hard as to break the tools in felling them, ſo they are ſeldom cut down for fire-wood, being difficult to burn; but the wood is of great uſe to the ſugar-planters, for making of wheels and cogs for the ſugar-mills, &c. It is alſo frequently brought to Europe, and wrought into bowls, and other utenſils are made of the wood.

This tree can only be propagated by ſeeds, which muſt be procured from the countries where it naturally grows; theſe muſt be freſh, otherwiſe they will not grow; when they arrive, they ſhould be ſown in pots filled with light earth, and plunged into a good hot-bed: if the ſeeds are good, and the bed in which they are plunged is of a proper temperature of heat, the plants will appear in ſix weeks or two months after; and in ſix weeks will grow to be of ſtrength enough more for tranſplanting; then they ſhould be carefully taken out of the ſeed-pots, ſo as to preſerve their roots as entire as poſſible, and each planted in ſeparate ſmall pots filled with light earth, and plunged into a new hot-bed of tanners bark, where they muſt be ſhaded from the ſun till they have taken freſh root; then they muſt be treated in the ſame manner as other tender exotic plants from warm countries, admitting a large ſhare of free air to them when the weather is warm: they will require to be frequently refreſhed with water in warm weather, but it muſt be given them with caution, for too much wet will infallibly deſtroy them. While the plants are young, they may be kept during the ſummer ſeaſon in a hot-bed of tanners bark under a frame; but in the autumn they muſt be removed into the bark-ſtove, and plunged into the hot-bed of tan, where they ſhould conſtantly remain, and muſt be treated in the ſame manner as other tender plants, being careful not to give them too much water in the winter, when it is very prejudicial to them, and in ſummer they ſhould have a large ſhare of free air admitted to them every day. With this treatment the plants will thrive very well, but they are plants of ſlow growth in their own country, ſo cannot be expected to make great progreſs in Europe.

The ſecond ſort has many ſmall leaves placed along the midrib by pairs, which are rounded and obtuſe at their ends, but narrow at their baſe: they are of the ſame conſiſtence with thoſe of the former ſort, but of a darker green colour; the flowers are produced in looſe bunches toward the end of the branches, which are of a fine blue colour, and their petals are fringed on their edges. This is called in ſome of the iſlands Baſtard Lignum Vitæ; I received it from Antigua by that title. It requires the ſame treatment as the firſt ſort, and is propagated by ſeeds in the ſame way.

I have alſo received ſpecimens from the iſland of Barbuda of one, which ſeems different from either of thoſe before-mentioned: the branches have the ſame appearance with thoſe of the firſt ſort, but the leaves are larger and indented at their extremities, and are placed all round the branches, on very ſhort footſtalks; the flowers were broken off, ſo I cannot determine the difference between them, but by all appearance they ſeem to be of the ſame genus.

The third ſort has been long an inhabitant in ſome of the curious gardens in England and Holland, but ſeldom produces flowers in Europe. This grows naturally at the Cape of Good Hope, from whence the ſeeds were brought firſt to Holland, where it paſſed for a ſpecies of Acacia, until it produced its flowers; which, by the account given of them by the late Dr. Boerhaave, were of the butterfly kind; but whether Dr. Linnæus has ſeen the flowers or not, I cannot ſay; however, he has removed it from that claſs of plants, and has added it to this genus; and as I have not yet ſeen the flowers, ſo I do not know if it is rightly placed. The plants retain their leaves all the year, and will live in a good green-houſe in winter, but in ſummer muſt be placed abroad with other green-houſe plants. It is of ſlow growth, and is with difficulty propagated by layers.

GUILANDINA. Lin. Gen. Plant. 464. Bonduc. Plum. Nov. Gen. 25. tab. 39. The Nickar-tree.

The Characters are,

The empalement of the flower is of one leaf, is bell-ſhaped, and cut at the top into five equal ſegments: the flower has five concave ſpear-ſhaped petals which are equal, and ſit cloſe to the empalement, into which they are inſerted. It hath ten awl-ſhaped ſtamina which are erect, and inſerted in the empalement, being alternately ſhorter than each other, and terminated by obtuſe ſummits. In the center is ſituated an oblong germen, ſupporting a ſlender ſtyle the length of the ſtamina, crowned by a ſingle ſtigma. The germen afterward becomes a rhomboid pod, with a convex ſuture on the upper ſide; it is ſwelling and compreſſed, having one cell, including oval hard ſeeds, which are ſeparated by partitions.

This genus of plants is ranged in the firſt ſection of Linnæus's tenth claſs, in which he includes the plants whoſe flowers have ten ſtamina and one ſtyle.

The Species are,

1. Guilandina (*Bonduc*) aculeata pinnis ovatis foliolis aculeis ſolitariis. Lin. Sp. 545. *Prickly Guilandina with oval-winged leaves, whoſe ſmall leaves are armed with ſingle ſpines.* Bonduc vulgare majus polyphyllum. Plum. Nov. Gen. 25. *Common greater Bonduc, having many leaves, called yellow Nickar.*
2. Guilandina (*Bonducella*) aculeata, pinnis oblongo-ovatis foliolis aculeis geminis. Lin. Sp. 545. *Prickly Guilandina with oblong oval leaves, having ſpines by pairs.* Bonduc vulgare minus polyphyllum. Plum. Nov. Gen. 25. *Smaller common Bonduc, or Nickar-tree having many leaves, called gray Nickar.*
3. Guilandina (*Glabra*) inermis foliis bipinnatis, foliolis ovatis acutis alternis. *Smooth Guilandina with double winged leaves, whoſe ſmall leaves are oval-pointed and alternate.*
4. Guilandina (*Moringa*) inermis, foliis ſubpinnatis, foliolis inferioribus ternatis. Flor. Zeyl. 155. *Smooth Guilandina with winged leaves, whoſe under ſmall leaves are trifoliate.* Moringa Zeylanica, foliorum pinnis pinnatis, flore majore, fructu anguloſo. Burm. Zeyl. 162. tab. 75. *Morunga of Ceylon, with double-winged leaves, a larger flower, and an angular fruit.*
5. Guilandina (*Dioica*) inermis foliis bipinnatis baſi apiceque ſimpliciter pinnatis. Lin. Sp. 546. *Guilandina with ſmooth branches, doubly winged leaves, whoſe baſe and tops are ſingle winged.* Bonduc Canadenſe polyphyllum, non ſpinoſum, mas & fœmina. Du Hamel. *Canada Nickar-tree having many leaves, which have no ſpines, and are male and female in different plants.*

The firſt and ſecond ſorts grow naturally in moſt of the iſlands in the Weſt-Indies, where they twine their ſtalks about any neighbouring ſupport, and riſe to the height of twelve or fourteen feet. The leaves of the firſt ſort are near a foot and a half long, and are compoſed of ſix or ſeven pair of pinnæ, or wings, each of which has as many pair of lobes, or ſmall leaves ſet along the midrib; theſe are oval and entire; the foot-ſtalk or principal midrib of the leaf, is armed with ſhort, crooked, ſingle thorns, which are placed irregularly; the ſtalks are cloſely armed with the like thorns, which are larger. The ſtalks at firſt grow erect, but afterward they twine about the neighbouring trees or ſhrubs, being too weak to ſtand without ſupport: the flowers come out in long ſpikes from the wings of the ſtalk; they are compoſed of five concave yellow petals, which are equal; in the center is ſituated the oblong germen, ſurrounded by ten ſtamina. After the flower is paſt, the germen becomes a broad thick pod, about three inches long and two broad, cloſely armed with ſlender ſpines, opening with two valves, each incloſing two hard ſeeds about the ſize of children's marbles, of a yellowiſh colour,

The ſecond ſort differs from the firſt, in having much ſmaller leaves, which are ſet cloſe together; and below each pair of lobes are ſituated two ſhort ſtiff crooked ſpines, which are placed oppoſite; the flowers are of a deeper yellow colour than thoſe of the firſt ſort, and the ſeeds are of an Aſh-colour.

The third ſort was diſcovered by the late Dr. Houſtoun at Campeachy, from whence he ſent the dried ſamples to England, but there was no fruit on the trees at the time when he was there; but he mentions that this ſort had an upright ſtem, which was of a large ſize, dividing into many branches; theſe are garniſhed with double winged leaves, which are ſmooth; the wings come out altenrnate, each leaf being compoſed of four pair, but the lobes are placed oppoſite upon the middle rib; they are oval, but end in a point, and are of a light green colour.

The fourth ſort grows naturally in the iſland of Ceylon, and in ſeveral places on the Malabar coaſt, from whence the ſeeds were brought to England. This in its native country riſes to the height of twenty-five or thirty feet, with a ſtrong ſtem, covered with a ſmooth bark, which in the young branches is green, but on the older it is of an Aſh-colour; the root grows knobbed, and very thick. This, when young, is ſcraped and uſed by the inhabitants as Horſe-radiſh is in Europe, having much the ſame ſharp taſte; the branches are garniſhed with decompounded winged leaves; thoſe which are ſituated at the baſe have but three leaves, but above, the leaves are branched out into ſeveral diviſions, which are again divided into ſmaller, having each five or ſix pair of oval lobes, terminated by an odd one; they are of a light green, and a little hoary on their under ſide. The flowers are produced in looſe bunches from the ſide of the branches; they are compoſed of an unequal number of petals, from five to ten; they have ten ſhort ſtamina ſurrounding the germen, which afterward turns to a long taper pod, including ſeveral angular ſeeds, covered with a thin membrane. Theſe have a flavour like the root.

Theſe four ſorts are natives of warm countries, ſo will not live through the winter in England, unleſs they are placed in a warm ſtove, and the pots plunged into the tan-bed. They are propagated by ſeeds, but thoſe of the two firſt ſorts are ſo hard, that unleſs they are ſoaked two or three days in water before they are put into the ground, or placed under the pots in the tan-bed to ſoften their covers, they will remain years in the ground without vegetating: when the plants come up, they will be fit to tranſplant in a ſhort time; then they ſhould be each tranſplanted into a ſmall pot filled with light freſh earth, and plunged into a moderate hot-bed of tanners bark, ſhading them till they have taken freſh root; then they muſt be treated in the ſame manner as other tender exotic plants, giving them a large ſhare of air in warm weather, and but little water; and when the plants have advanced to be too tall to remain in the frames, they muſt be removed into the bark-ſtove and plunged into the hot-bed, where they will make great progreſs, provided they have not too much water, eſpecially during the winter ſeaſon, for theſe plants are very impatient of moiſture in cold weather.

The fourth ſort requires the ſame treatment as thoſe before-mentioned, but the ſeeds will grow without being ſteeped in water; and the plants are with difficulty ſhifted from one pot to another, for their roots are large, fleſhy, and have but few fibres; ſo that unleſs great care is taken, all the earth will fall away from them, which often cauſes their ſtalks to decay almoſt to the root, and ſometimes occaſions the loſs of the plants. This plant muſt be ſparingly watered at all times, but particularly in cold weather, when moiſture will cauſe them to rot in a ſhort time.

The fifth ſort grows naturally in Canada, from whence the plants were brought to Paris, where it has been ſome years cultivated; but about fourteen years paſt, it was firſt brought to England. This, in the country where it naturally grows, riſes with an erect ſtem to the height of thirty feet or more, dividing into many branches, which are covered with a bluiſh Aſh-coloured bark very ſmooth, and garniſhed with large decompounded winged leaves which are of the oval ſhape, very ſmooth and entire, but are ranged alternate on the midrib; theſe fall off in the autumn, and new ones come out late in the ſpring.

There are male and female of this ſort in different plants; as theſe have not as yet flowered in any of the Engliſh gardens, ſo I can give no farther account of them nor of the fruit, having never ſeen any of them. This ſort lives abroad in the open air, and is never hurt by froſt. It is propagated by cutting off ſome of the horizontal roots, which will cauſe them to ſhoot upward, ſo it may be taken from the old root, and planted in pots, whereby the plant may be multiplied, or by ſuckers from the root. It requires a light ſoil, not too moiſt.

GUNDELIA. Tourn. Cor. 51. tab. 586. Lin. Gen. Plant. 828. Hacub. Vaill. Ac. Reg. Scien. 1718.

This plant was ſo named by Dr. Tournefort, in honour of Dr. Gundelſcheimer, who found it in his travels in company with Dr. Tournefort in the Levant.

The CHARACTERS are,

It hath an uniform tubulous flower, compoſed of many hermaphrodite florets, which are incircled by leaves. They have but one petal which is cloſed at the bottom, but ſwells at the top, where it is ſlightly cut into five ſegments: they have five ſhort hairy ſtamina, terminated by long cylindrical ſummits. The oval germen is ſituated at the bottom of the flower, crowned by ſmall ſcales, ſupporting a ſlender ſtyle which is longer than the petal, terminated by two revolving ſtigmas. The germen afterward becomes a roundiſh ſingle ſeed incloſed in the common receptacle, which is conical, and the ſeeds are ſeparated by a chaffy down.

This genus of plants is by Tournefort referred to his twelfth claſs, which contains the herbs with floſculous flowers. Dr. Linnæus ranges it in the fifth ſection of his nineteenth claſs, intitled Syngeneſia Polygamia ſegregata, which includes thoſe plants whoſe flowers have a common empalement, and each of the florets are included in another.

We have but one diſtinct SPECIES of this genus at preſent in England, viz.

GUNDELIA. Lin. Sp. Plant. 814. There is no Engliſh title to this plant, but there are two varieties of it mentioned by Tournefort, which are ſuppoſed to ariſe from the ſame ſeeds, as they were found growing promiſcuouſly together. Theſe are,

1. GUNDELIA (*Tournefortii*) Orientalis acanthi aculeati foliis, floribus intenſè purpureis, capite araneoſâ lanugine obſito. Tourn. Cor. 51. *Eaſtern Gundelia with prickly Bear's-breech leaves, deep purple flowers, and a head covered with a down like a cobweb.*
2. GUNDELIA (*Glabro*) Orientalis, acanthi aculeati folio, capite glabro. Tourn. Cor. 51. *Eaſtern Gundelia with a prickly Bear's-breech leaf, and a ſmooth head.*

This plant was diſcovered by Dr. Gundelſcheimer, in company with Tournefort, near Baibout in Armenia, but has ſince been foundgrowing naturally in ſeveral places in the Levant, where it is generally found in dry ſtrong land. The ſtalks of this plant ſeldom riſe more than a foot and a half high; the under leaves are long, narrow, and ſawed on their edges, their teeth ending in a ſpine; the other leaves are broader, which are irregularly ſlaſhed to the midrib, and armed at the points with ſharp prickles; the ſtalks divide upward into ſeveral branches, which are armed with leaves of the ſame form, but are narrower; and each is terminated by a conical head of flowers, reſembling thoſe of Fuller's Thiſtle, being ſurrounded at the baſe by a circle of long, narrow, prickly leaves: theſe heads are compoſed of many hermaphrodite florets, which are ſhut up in the ſcales, each having an empalement, and a germen with five ſtamina ſurrounding it; but there are few of the ſeeds which ripen perfectly in each head, in the natural places of its growth. If rain happens at the time when the plants are in flower, the germen periſhes, which is the caſe with ſeveral other of thoſe plants whoſe flowers are collected into heads.

Theſe plants are propagated by ſeed, which ſhould be ſown the beginning of March, in a warm dry border of freſh, but lean earth, in the place where the plants are deſigned to remain. When the plants come up, they muſt be carefully cleared from weeds; as they grow large, they ſhould be thinned, leaving the plants which are deſigned to remain, about two feet aſunder, that they may have room to ſpread. After this there is no other culture required, but to keep them clear from weeds; and if the froſt ſhould prove ſevere in winter, the plants ſhould be covered with ſtraw or Peas-haulm to protect them, but this covering muſt be taken off in mild weather; in two years they will produce their flowers, when they will make a fine appearance amongſt other hardy plants in the pleaſure-garden. They flower in May, and the plants loſe their ſtalks and leaves in autumn, but their roots will abide many years.

GYPSOPHYLA. Lin. Gen. Plant. 498. We have no Engliſh title for this genus.

The Characters are,

The flower hath a permanent, angular, bell-ſhaped empalement, cut into five parts at the top. It hath five oval blunt petals, which ſpread open, and ten awl-ſhaped ſtamina, terminated by roundiſh ſummits. In the center is ſituated a globular germen, ſupporting two ſlender ſtyles, crowned by ſingle ſtigmas. The germen afterward becomes a globular capſule with one cell, opening with five valves, filled with ſmall roundiſh ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's tenth claſs, which includes thoſe plants whoſe flowers have ten ſtamina and two ſtyles.

The Species are,

1. Gypsophyla (*Aggregata*) foliis mucronatis recurvatis, floribus aggregatis. Lin. Sp. Plant. 406. *Gypſophyla with pointed recurved leaves, and flowers gathered in a head.* Lychnis Hiſpanica kali folio multiflora. Tourn. Inſt. R. H. 338. *Spaniſh Lychnis with a Glaſſwort leaf and many flowers.*
2. Gypsophyla (*Faſtigiata*) foliis lanceolato-linearibus, obſoletè triquetris lævibus obtuſis ſecundis. Lin. Sp. Plant. 407. *Gypſophyla with narrow ſpear-ſhaped leaves, having three blunt angles, and ſmooth obtuſe leaves in cluſters.* Saponaria caule ſimplici, foliis linearibus ex alis foliorum confertis teretibus. Hort. Cliff. 166. *Sopewort with a ſingle ſtalk, very narrow leaves, coming out in cluſters from the wings of the ſtalks.*
3. Gypsophyla (*Proſtrata*) foliis lanceolatis lævibus, caulibus diffuſis, piſtillis corollâ campanulatâ longioribus. Lin. Sp. Plant. App. 1195. *Gypſophyla with ſmooth ſpear-ſhaped leaves, diffuſed ſtalks, and the pointal longer than the petal, which is bell-ſhaped.*
4. Gypsophyla (*Perfoliata*) foliis ovato-lanceolatis, ſemiamplexicaulibus. Lin. Sp. Plant. 408. *Gypſophyla with oval ſpear-ſhaped leaves, half embracing the ſtalks.* Lychnis Orientalis, ſaponariæ folio & facie, flore parvo & multiplici. Tourn. Cor. 24. *Eaſtern Lychnis with the leaf and appearance of Sopewort, having many ſmall flowers.*
5. Gypsophyla (*Paniculata*) foliis lanceolatis ſcabris, floribus dioicis corollis revolutis. Lin. Sp. Plant. 407. *Gypſophyla with rough, ſpear-ſhaped leaves, male and female in different plants, and the petals of the flowers recurved.* Alſine fruteſcens caryophylli folio, flore parvo albo. Gerb. *Shrubby Chickweed with a Clove Gilliflower leaf, and a ſmall white flower.*

The firſt ſort grows naturally in the ſouth of France, Spain, and Italy, upon the mountains. This hath a perennial root, from which ariſe many narrow leaves ending in acute points, which are recurved; the ſtalks riſe about a foot high, garniſhed with narrower leaves placed oppoſite, and at ſome of the joints there are ſmaller leaves growing from the ſtalks in cluſters; the upper part of the ſtalk divides into ſmaller branches, each being terminated by a cloſe bunch of ſmall white flowers. Theſe appear in July, and are ſucceeded by ſmall oval capſules, filled with ſmall ſeeds.

The ſecond ſort is ſomewhat like the firſt, but the leaves are much narrower, and almoſt three-cornered; they are placed in cluſters, which come out from the ſide of the ſtalk; the bunches of the flowers are ſmaller, and not ſo cloſely joined. This hath a perennial root, and grows naturally upon the Helvetian mountains.

The third ſort hath a perennial root, from which ariſe ſmooth ſpear-ſhaped leaves in cluſters; the ſtalks are near a foot long, but are proſtrate on the ground; the flowers have a purpliſh caſt, and the ſtamina are much longer than the petals of the flowers. This flowers in June and July, and the ſeeds ripen in autumn.

The fourth ſort grows naturally in the Levant, and alſo in Spain. It hath a ſtrong, fleſhy, fibrous root, which ſtrikes deep in the ground, ſending up ſeveral thick, fleſhy ſtalks, which riſe near two feet high, garniſhed with oval ſpear-ſhaped leaves, which half embrace the ſtalks with their baſe; the upper part of the ſtalk divides into many ſmaller branches, which are terminated with looſe bunches of ſmall white flowers. Theſe open in July, and the ſeeds ripen in autumn.

The fifth ſort grows naturally in Siberia and Tartary, the ſeeds of it were ſent me from Peterſburgh. This hath a perennial root, from which ariſe many branching ſtalks a foot and a half high, garniſhed with narrow ſmooth-pointed leaves, ſhaped like thoſe of Gilliflowers; at the top of the ſtalks are produced looſe cluſters of very ſmall white flowers, which appear at the ſame time with the former ſorts, and the ſeeds ripen in the autumn.

Theſe plants have no great beauty, ſo are rarely cultivated but in botanic gardens for the ſake of variety.

They are propagated by ſeeds, which ſhould be ſown in a bed of light earth, and when the plants are fit to remove, they may be tranſplanted into the places where they are deſigned to remain, and will require no other culture but to keep them clean from weeds; for the roots will continue ſeveral years, and annually produce flowers and ſeeds.

H.

HÆMANTHUS. Tourn. Inſt. R. H. 657. tab. 433. Lin. Gen. Plant. 394. Dracunculoides. Boerh. Ind. alt. 2. 226. [Αἵμανθος, of Αἷμα, blood, and Ἄνθος, flos, a flower, i. e. Blood-flower.]

The Characters are,

The flower has a permanent empalement of ſix leaves, which is large, and ſhaped like an umbel. It hath one erect petal, which is cut into ſix parts, having a ſhort angular tube, and ſix awl-ſhaped ſtamina, which are inſerted in the petal, but are longer, terminated by oblong proſtrate ſummits. The germen is ſituated under the flower, ſupporting a ſingle ſtyle the length of the ſtamina, crowned by a ſingle ſtigma. The germen afterward becomes a roundiſh berry with three cells, each containing one triangular ſeed.

This genus of plants is ranged in the firſt ſection of Linnæus's ſixth claſs, intitled Hexandria Monogynia, which includes the plants whoſe flowers have ſix ſtamina and one ſtyle.

The Species are,

1. Hæmanthus (*Coccineus*) foliis linguiformibus planis lævibus. Prod. Leyd. 42. *Blood-flower with plain, tongue-ſhaped, ſmooth leaves.* Hæmanthus Africanus. H. L. Bat. *African Blood-flower, or Cape Tulip.*
2. Hæmanthus (*Carinatus*) foliis longioribus carinatis. *Blood-flower with longer keel-ſhaped leaves.*
3. Hæmanthus (*Puniceus*) foliis lanceolato ovatis undulatis erectis. Hort. Cliff. 127. *Blood-flower with ſpear-ſhaped, waved, erect leaves.* Hæmanthus colchici foliis perianthio herbaceo. Hort. Elth. 167. *Blood-flower with Meadow Saffron leaves, and an herbaceous involucrum.* Dracunculoides. Boerh. Ind. alt. 2. 226. *Baſtard Dragon.*

The firſt ſort has been many years in ſeveral curious gardens in Europe, where it hath ſeldom flowered. This hath a large bulbous root, from which in the autumn comes out two broad flat leaves, of a fleſhy conſiſtence, ſhaped like a tongue, which turn backward on each ſide, and ſpread flat on the ground, ſo have a ſingular appearance all the winter; and in the ſpring theſe leaves decay, ſo that from the end of May to the beginning of Auguſt, they are deſtitute of leaves: when theſe produce their flowers, it is always in the autumn, juſt before the new leaves come out. In the books where this plant is figured, the flowers are repreſented growing upon a ſtrong upright foot-ſtalk; but all thoſe which I have ſeen in flower, never have riſen more than two or three inches from the bulb, with a large cluſter of bright red flowers, incloſed in a common leafy-coloured empalement; theſe were tubulous, with one petal cut into ſix parts, each having ſix long ſtamina, ſtanding out beyond the petal, and in the center appears the germen ſitting under the flower, ſupporting a ſingle ſtyle, crowned with a ſtigma. The germen never ripens to a ſeed in England, but decays with the flower, and then the green leaves grow and ſpread on the ground.

The ſecond ſort hath a large bulbous root like the firſt, which ſends out three or four leaves, that grow a foot long or more; theſe are not flat like thoſe of the other, but are hollowed like the keel of a boat, and ſtand more erect than thoſe of the former ſort, but are not quite ſo broad; the flowers of this are like thoſe of the firſt, but are of a paler red; this is certainly different from the other. I received the roots of this from Dr. Van Royen, profeſſor of botany at Leyden.

The third ſort hath roots compoſed of many thick fleſhy tubers, which join at the top, where they form a head, out of which ariſes a fleſhy ſpotted ſtalk, like that of the dragon, which ſpreads out at the top into ſeveral ſpear-ſhaped leaves, which are waved on their edges. The ſtalks grow about a foot high, and the leaves are ſix or eight inches long, and two broad in the middle; from the ſide of this ſtalk near the ground, breaks out a ſtrong fleſhy foot-ſtalk, about ſix or eight inches long, ſuſtaining at the top a large cluſter of flowers, included in one common empalement or covering, which is permanent; the flowers are ſhaped like thoſe of the other ſorts, but are of a yellowiſh red colour. Theſe appear in May, June, or July, and are ſucceeded by berries which are of a beautiful red colour when ripe.

The two firſt ſorts are with difficulty propagated in Europe, for their roots put out offſets but ſparingly, ſo the gardens in Holland are ſupplied with them from the Cape of Good Hope, where they naturally grow, and produce ſeeds; the plants are too tender to thrive in this country in winter in the open air, therefore the roots muſt be planted in pots filled with light loamy earth, and, in the winter, placed in a dry glaſs-caſe, where, during that ſeaſon, the leaves will be in full vigour, ſo will make a pretty appearance, when intermixed with other plants in the ſtove; and though they ſeldom flower here, yet are they worthy of a place in every garden where there is conveniency of keeping them. The roots may be taken up when their leaves are decayed, and kept out of the ground till Auguſt, when they ſhould be new potted, and may remain abroad till the end of September, at which time they may be removed into the glaſs-caſe; and during the time they are growing, will require to have frequent waterings, but it muſt not be given to them in large quantities.

If a border is made either againſt the front of the green-houſe or ſtoves, which may be contrived ſo as to be covered with glaſſes in winter, in which theſe roots, with the African Gladiolus's, Ixia's, Perſian Cyclamens, &c. are planted in the full ground, they will flower more conſtantly, and the foot-ſtalks will riſe much higher than thoſe kept in pots.

The third ſort is alſo a native of the Cape of Good Hope, from whence it was firſt brought to Holland, where it has been propagated and diſperſed over Europe; this may be propagated by parting of the roots; the beſt time for this is in the ſpring, before the plants put out new ſtalks, which is alſo a right time to ſhift and new-pot them; but as the roots do not multiply very faſt in offſets, the beſt way is to propagate them from ſeeds, which they ripen plentifully in England; theſe ſhould be ſown ſoon after they are ripe, in pots filled with light earth, and kept in the ſtove all the winter; if theſe pots are plunged into the tan-bed in the bark-ſtove, in the vacancies between the plants, the earth will be kept warm, and will not dry ſo faſt, as when they are placed in a dry ſtove, ſo the ſeeds will be ſooner prepared to vegetate; in the ſpring the pots may be taken out of the ſtove, and plunged into a hot-bed, which will bring up the plants; theſe muſt have air admitted to them every day in mild weather, to prevent their drawing up weak; and when they are fit to remove, they may be each planted in a ſeparate ſmall pot filled with light earth, and plunged into the hot-bed again, to promote their taking new root; then they muſt be gradually hardened, and afterward may be removed into the dry ſtove, where they ſhould conſtantly remain, otherwiſe the plants will not thrive and flower in this country. In the winter ſeaſon they muſt not have too much wet, for as their roots are fleſhy and ſucculent, ſo they are apt to rot with moiſture. In the ſummer they muſt have a large ſhare of air in warm weather, and require to be frequently watered, eſpecially during the time of their flowering.

HÆMATOXYLUM. Lin. Gen. Plant. 417. Bloodwood, Logwood, or Campeachy Wood.

The Characters are,

The flower hath a permanent empalement, which is cut into five oval ſegments. It hath five oval petals which are equal, and larger than the empalement, and ten awl-ſhaped ſtamina, which are longer than the petals, terminated by ſmall ſummits. In the center is ſituated an oblong oval germen, ſupporting a ſingle ſtyle, crowned by a thick indented ſtigma. The germen afterward becomes a compreſſed obtuſe capſule, with one cell, opening with two valves, containing two or three oblong kidney-ſhaped ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's tenth claſs, intitled Decandria Monogynia, which includes thoſe plants whoſe flowers have ten ſtamina and one ſtyle.

We have but one Species of this genus, viz.

Hæmatoxylum (*Campechianum*). Hort. Cliff. 161. *Logwood*, Lignum Campechianum, ſpecies quædam. Sloan. Cat. Jam 213. *Campeachy Wood.*

This tree grows naturally in the Bay of Campeachy, at Honduras, and other parts of the Spaniſh West-Indies, where it riſes from ſixteen to twenty-four feet high. The ſtems are generally crooked, and very deformed, and are ſeldom thicker than a man's thigh. The branches come out on every ſide; they are crooked, irregular, and armed with ſtrong thorns, garniſhed with winged leaves, compoſed of three or four pair of lobes, which are obtuſe, and indented at the top. The flowers come out in a racemus from the wings of the leaves, ſtanding erect; they are of a pale yellowiſh colour, with a purple empalement, and are ſucceeded by flat oblong pods, each containing two or three kidney-ſhaped ſeeds.

The wood of this tree is brought to Europe, where it is uſed for dyeing purples, and for the fineſt blacks, ſo is a valuable commodity; but the Spaniards, who claim a right to the poſſeſſion of thoſe places where it naturally grows, are for excluding all other countries from cuting of the wood, which has occaſioned many diſputes with their neighbours, but particularly with the Engliſh; this it is to be hoped will ſoon be over, as there are ſome of the planters in Jamaica, and the other iſlands in America, belonging to the crown of Great-Britain, who have propagated this tree in ſo great plenty, as to have hopes of ſupplying the demand for this wood in Britain in a very few years; for the trees grow ſo faſt there, as to be fit for uſe in ten or twelve years years from ſeed; and as they produce great plenty of ſeeds in the Britiſh colonies, ſo thoſe ſeeds ſcattering about, the plants come up in all the neighbouring lands, therefore will ſoon be like an indigenous plant of the country.

Some of the planters in Jamaica have incloſed their eſtates with hedges formed of theſe trees, which are very ſtrong and durable; but where the hedges are cut, it will greatly retard the growth of the trees, ſo that thoſe who propoſe to make an advantage by the propagation of the wood, ſhould ſow the ſeeds upon ſwampy lands, which may be unfit for growing of ſugar, and permit all their branches to remain, which will be of great uſe in augmenting the bulk of their ſtems; and if, while the plants are young, they are kept clean from weeds, &c. it will be of great advantage in promoting of their growth. I have been credibly informed by ſome of the planters in Jamaica, that they have had ſome plants of this ſort upward of ten feet high in three years, ſo that it requires but few years to raiſe a ſupply of this wood, ſufficient to anſwer all the demands for it.

This plant is preſerved in ſome curious gardens in England, for the ſake of variety. The ſeeds are frequently brought from America, which, if freſh, readily grow when ſown upon a good hot-bed; and if the plants are kept in a moderate hot-bed, they will grow to be upward of a foot high the ſame year, and, while the plants are young, they are generally well furniſhed with leaves; but afterward they make but little progreſs, and are frequently but thinly clothed with leaves. Theſe plants are very tender, ſo ſhould be conſtantly kept in the bark-ſtove, where, if they are duly watered, and the ſtove kept in a good degree of heat, the plants may be preſerved very well. There are ſome of theſe plants now in England, which are upward of ſix feet high, and as thriving as thoſe in their native ſoil.

HALESIA. Lin. Gen. Plant. 596.

The CHARACTERS are,

The flower hath a ſmall permanent empalement of one leaf, indented in four parts; it hath a bell-ſhaped ſwelling flower of one petal, divided at the brim into four lobes, and from twelve to ſixteen ſtamina, ſhorter than the petal, terminated by oblong erect ſummits; the germen is ſituated below, is oblong, ſupporting a ſlender ſtyle longer than the petal, crowned by a ſimple ſtigma; the germen afterward becomes an oblong nut, narrowed at both ends, having four angles, with two cells, incloſing a ſingle ſeed in each.

This genus of plants is ranged in the firſt ſection of Linnæus's eleventh claſs, intitled Dodecandria Monogynia, the flower having twelve ſtamina and one ſtyle.

The SPECIES are,

1. HALESIA (*Tetraptera*) foliis lanceolato-ovatis, petiolis glanduloſis. Lin. Sp. 636. *Haleſia with oval ſpear-ſhaped leaves, whoſe foot-ſtalks are glandulous.* Frutex padi foliis ſerratis, floribus monopetalus albis campaniformibus, fructu craſſo tetragono. Cateſb. Hiſt. Carol. 1. p. 64.
2. HALESIA (*Diptera*), foliis ovatis, petiolis lævibus. Lin. Sp. 636. *Haleſia with oval leaves having ſmooth foot-ſtalks.*

This genus of plants received its title from the late learned and reverend Doctor Hales, miniſter of Teddington, near Hampton-Court.

Both the ſorts grow naturally in South-Carolina; the firſt on the banks of Santee river, where it frequently comes up with two or three ſtems from the ſame root, which riſe from fifteen to twenty feet high, ſending out branches toward their tops, garniſhed with oval ſpear-ſhaped leaves, ſawed on their edges: the flowers are produced on the ſide of the branches in cluſters, from two or three to ſix or ſeven in each; they are bell-ſhaped, hanging downward, of one petal, white, which is indented in four parts at the brim; theſe are ſucceeded by oblong nuts, having four wings and four cells, each containing one oblong ſeed.

The ſecond ſort hath much reſemblance to the firſt, the leaves are oval, and the foot-ſtalks are ſmooth; the fruit has but two angles.

Theſe plants are propagated by ſeeds, when they can be procured freſh from the places of their natural growth. Theſe ſhould be ſown in pots as ſoon as the ſeeds arrive, plunging the pots into the ground, in a ſituation where they may have only the morning ſun. The ſeeds often remain a year in the ground, therefore the earth in the pots ſhould not be diſturbed, until there is no probability of the ſeed growing. When the plants appear, they ſhould be ſcreened from the ſun, and frequently, but not too plentifully watered; for while the plants are young, much moiſture will rot their ſhanks. The following autumn, the pots ſhould be placed in a common frame, where the plants may enjoy the free air in mild weather, and be ſcreened from froſt. The ſpring following, before the plants begin to ſhoot, they ſhould be each put into a ſeparate ſmall pot, plunging them in a frame, where they ſhould be ſhaded from ſun; and in the ſummer placed in a ſhady ſituation, ſcreening them in winter; and the ſpring following they may be turned out of the pots, and planted in the full ground where they are deſigned to remain.

HALICACABUS PEREGRINA. See CARDIOSPERMUM.

HALIMUS. See ATRIPLEX.

HALLERIA. Lin. Gent. Plant. 679. Caprifolium. Boerh. Ind. alt. 2. p. 226. *African Fly Honeyſuckle.*

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, which is cut into three parts at the top, the upper ſegment being much broader than the other. It hath one petal of the grining kind. The bottom of the tube is roundiſh. The chaps are ſwollen and inflexed, the brim is erect and oblique, cut into four ſegments, the upper being longer than the others, and is blunt, with an indenture at the top; the two ſide ones are ſhorter, and pointed, the lower is very ſhort and acute. It hath four ſtamina, which are briſtly, two being longer than the other, terminated by twin ſummits. In the bottom of the tube is ſituated an oval germen, with a ſtyle longer than the ſtamina, crowned by a ſingle ſtigma. The germen afterward becomes a roundiſh berry with two cells, each containing one hard ſeed.

This genus of plants is ranged in the ſecond ſection of Linnæus's fourteenth claſs, intitled Didynamia Angioſpermia, which includes the plants with a ringent flower, which have two long and two ſhorter ſtamina, and the ſeeds are included in a capſule.

We have but one SPECIES of this genus, viz.

HALLERIA (*Lucida*). Hort. Cliff. 323. This plant has its title from Dr. Haller, who was profeſſor of botany at Gottingen, in Germany. Caprifolium Africanum folio pruni leviter ſerrato, flore ruberrimo, baccâ nigrâ. Boerh. Ind. alt. 2. 226. *African Fly Honeyſuckle, with a Plumb leaf lightly ſawed, a very red flower, and a black berry.*

The Engliſh name which I have here added, has been given to this plant by ſome gardeners, who obſerved that the ſhape of the flower had ſome reſemblance to that of the Upright, or Fly Honeyſuckle, and for want of an Engliſh name gave this to it; or they might take it from the Latin name, by which it was called by Dr. Boerhaave, who made it a ſpecies of Honeyſuckle.

This plant grows to the height of ſix or eight feet, having a woody ſtem, which is well furniſhed with branches; theſe have oval ſawed leaves, which are placed oppoſite, and continue green through the year; the flowers come out ſingly, and are of a red colour, but, being intermixed with the leaves, are not ſeen unleſs they are looked after, for they grow ſcatteringly on the branches; theſe come out in June, and the ſeeds ripen in September; the leaves are green in winter, ſo the plants make a variety in the green-houſe during that ſeaſon.

It may be propagated by cuttings, which, if planted in pots filled with light earth in June, and plunged into a gentle hot-bed, will ſoon take root; theſe plants may be expoſed in ſummer, and will require plenty of water in that ſeaſon; in winter they muſt be houſed with Myrtles, and other hardy exotic plants, which require a large ſhare of air in mild weather.

HAMAMELIS. Lin. Gen. Plant. 155. Trilopus. Mitch. Gen. 22. *The Witch Hazel.*

The Characters are,

It is male and female in different plants; the male flowers have a four-leaved empalement, and four narrow petals, which are reflexed; they have four narrow ſtamina, which are ſhorter than the petals, terminated by horned reflexed ſummits. The female flowers have a four-leaved involucrum, in which are four flowers; theſe have a four-leaved empalement, which is coloured; they have four narrow petals, which are reflexed, and four nectariums adhering to the petals. In the center is ſituated an oval hairy germen, ſupporting two ſtyles, crowned by headed ſtigmas. The germen afterward becomes an oval capſule ſitting in the involucrum, having two cells, each containing one hard, oblong, ſmooth ſeed.

This genus of plants is ranged in the ſecond ſection of Linnæus's fourth claſs, but properly belongs to the ſecond ſection of his twenty-ſecond claſs, which includes thoſe plants which have male and female flowers in different plants, whoſe female flowers have two ſtyles.

We have but one Species of this genus in the Engliſh gardens at preſent, viz.

Hamamelis (*Virginiana*). Flor. Virg. 139. *The Witch Hazel.* Piſtachia Virginiana nigra, coryli foliis. Pluk. Alm. 296. *Black Virginia Piſtachia with Hazel leaves.*

This plant grows naturally in North America, from whence the ſeeds have been brought to Europe, and many of the plants have been raiſed in the Engliſh gardens, where they are propagated for ſale by the nurſery gardeners. It hath a woody ſtem, from two to three feet high, ſending out many ſlender branches, garniſhed with oval leaves, indented on their edges, having great reſemblance to thoſe of the Hazel Nut, placed alternately on the branches; theſe fall away in autumn, and when the plants are deſtitute of leaves, the flowers come out in cluſters from the joints of the branches; theſe ſometimes appear the latter end of October, and often not till December, but are not ſucceeded by ſeeds in this country.

As the flowers of this ſhrub make very little appearance, ſo it is only preſerved in the gardens of the curious, more for the ſake of variety than its beauty.

This is propagated by laying down the young branches in autumn, which will take root in one year, provided they are duly watered in dry weather; but many of the plants which are in the gardens, have been produced from ſeeds which came from America; theſe ſeeds always remain a whole year in the ground, ſo they ſhould be ſown in pots, which may be plunged into the ground in a ſhady part of the garden, where they may remain all the ſummer, and require no other care but to keep the pots clean from weeds, and in very dry weather to water them now and then; in autumn the pots may be removed to a warmer ſituation, and plunged into the ground under a warm hedge; and if the winter ſhould prove very ſevere, they ſhould have ſome light covering thrown over the pots, which will ſecure the ſeeds from being deſtroyed.

In the ſpring the plants will come up, therefore as the ſeaſon grows warm, the pots may be removed where they may have the morning ſun till eleven o'clock; and if they are duly watered in dry weather, the plants will have made good progreſs by autumn, when they ſhould be tranſplanted, either into ſmall pots, or in a nurſery-bed, where in one, or at moſt two years time, they will be ſtrong enough to plant where they are deſigned to remain; they love a moiſt ſoil, and a ſhady ſituation.

HAMELLIA. Lin. Gen. 232.

The Characters are,

The empalement of the flower is ſmall, permanent, and cut into five acute ſegments; the flower is of one petal, having a long tube, whoſe brim is cut into five acute points; it hath five awl-ſhaped ſtamina inſerted to the middle of the petal, terminated by linear ſummits the length of the petal; and an oval germen, whoſe lower point is conical, ſupporting a ſlender ſtyle the length of the corolla, crowned by an obtuſe linear ſtigma: the germen afterward becomes an oval furrowed berry, with five cells, filled with ſmall compreſſed ſeeds.

This genus of plants is ranged in the firſt order of Linnæus's fifth claſs, intitled Pentandria Monogynia, the flower having five ſtamina and one ſtyle: it is named in honour of Monſieur du Hamel des Monceaux, member of the Academy of Sciences at Paris, and fellow of the Royal Society of London; a gentleman well known to the learned, by the many uſeful books he has publiſhed.

We know but one Species of this genus, viz.

1. Hamellia (*Patens*) racemis erectos. Jacq. Amer. 71. *Hamellia with erect ſpikes of flowers.*

This plant grows naturally in Africa, and alſo in the warm parts of America: I received the ſeeds from Paris, which were brought from Senegal by Mr. Adanſon, with the title of Mortura on the paper; and before that, received a drawing of the plant in flower, from the late Dr. Houſtoun, who found it growing naturally in America, where it has ſince been found growing by Mr. Jacquin, who has figured it.

It riſes with a ligneous ſtalk five or ſix feet high, ſending out ſeveral erect branches toward the top, garniſhed with oval woolly leaves, placed by threes round the branches, having red foot-ſtalks; the flowers terminate the branches in ſlender ſpikes; they are tubulous, and cut at their brims into five ſharp ſegments, ſtanding erect, of a bright red colour: theſe are not ſucceeded by ſeeds in England.

This plant is propagated by ſeeds, when they can be procured freſh from the countries where it grows naturally: theſe ſhould be ſown in ſmall pots, and plunged into a moderate hot-bed: the plants generally appear in about five or ſix weeks after, and ſhould then be treated in the ſame way as other plants from the ſame countries; giving them proper air in warm weather, and gently refreſhing them with water; and when they are fit to tranſplant, they ſhould be each planted in a ſmall pot, plunging them into the hot-bed again, where they ſhould be ſhaded from the ſun until they have taken new root, when they ſhould have air and moiſture according to the warmth of the ſeaſon. In the autumn the plants muſt be removed into the tan-ſtove, plunging the pots into the bed, where they ſhould be always continued: this flowers in July and Auguſt, when it makes a pretty appearance.

As the ſeeds of this plant are ſeldom brought to England, ſo the plant may be propagated by cuttings, which if planted in ſmall pots, plunged into a moderate hot-bed, and cloſely covered with either bell or hand-glaſſes, will put out roots in about ſix weeks, and may then be treated in the ſame way as the ſeedling plants.

HARMALA. See Peganum.

HASSELQUISTIA. Lin. Gen. 341.

The Characters are,

It is an umbelliferous plant, whoſe univerſal umbel is compoſed of ſix ſpreading rays; theſe are for the moſt part double; the greater involucrum has many ſhort briſtly *leaves; the proper empalement is very ſmall, and hath five indentures; the general umbel is half radiated; the outer flowers are fruitful, but thoſe in the diſk are barren; they have five petals, and five ſlender ſtamina longer than the petals, terminated by roundiſh ſummits: the turbinated germen is ſituated under the flower, ſupporting two ſlender recurved ſtyles, crowned by obtuſe ſtigmas; the germen afterward becomes an orbicular fruit, compoſed of two ſeeds having borders.*

This genus of plants is ranged in the ſecond order of Linnæus's fifth claſs, intitled Pentandria Digynia, the flowers having five ſtamina and two ſtyles.

It it named after Mr. Haſſelquiſt, who was a pupil of Dr. Linnæus.

1. Hasselquistia (*Ægyptiaca*). Amœn. Acad. 4. p. 370. *Egyptian Haſſelquiſtia.* Paſtinaca Orientalis, foliis eleganter inciſis. Buxb. Cent. 3. p. 16.

This plant is bennial, and being a native of warm countries, is with difficulty preſerved in England; for when the plants come up early in the ſpring, they do not perfect their ſeeds the ſame year: and thoſe plants which ariſe in the autumn, ſeldom live through the winter; therefore the ſureſt method to procure good ſeeds in this country, is to ſow the ſeeds in pots about the middle of Auguſt, placing the pots where they may have the morning ſun only, being careful to water them duly; and as weeds will come up in the pots to take them out, and where the plants are too cloſe, thin them; in October remove the pots into a common frame, where they may enjoy the free air in mild weather, but be ſcreened from froſt: in the ſpring following, if the plants are carefully turned out of the pots, and planted in the full ground, they will flower in June, and the ſeeds will ripen in Auguſt.

HAWTHORN. See Mespilus.

HAZEL. See Corylus.

HEDERA. Lin. Gen. Plant. 249. Tourn. Inſt. R. H. 612. tab. 384. *The Ivy-tree.*

The Characters are,

The flowers are diſpoſed in form of an umbel, having a ſmall involucrum indented in many parts. The empalement is cut into five parts, and ſits upon a germen. The flower hath five oblong petals, which ſpread open, whoſe points are incurved; they have five awl-ſhaped ſtamina, terminated by proſtrate ſummits, which are cut into two at their baſe. The germen, which is ſituated below the flower, ſupports a ſhort ſtyle, crowned by a ſingle ſtigma. The germen afterward becomes a globular berry with one cell, incloſing four or five large ſeeds, convex on one ſide, and angular on the other.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, which includes thoſe plants whoſe flowers have five ſtamina and but one ſtyle.

The Species are,

1. Hedera (*Helix*) foliis ovatis lobatiſque. Flor. Lapp. 91. *Ivy with oval lobed leaves.* Hedera arborea. C. B. P. 305. *Tree Ivy*; and the Hedera communis major. J. B. 2. 111. *Great common Ivy.*
2. Hedera (*Quinquefolia*) foliis quinatis, ovatis, ſerratis. Hort. Cliff. 74. *Ivy with leaves compoſed of five lobes, which are ſawed.* Vitis quinquefolia Canadenſis ſcandens. Tourn. Inſt. 613. *Climbing Canada Vine with five leaves, commonly called Virginia Creeper.*

The firſt ſort grows naturally in moſt parts of England, where it meets with any neighbouring ſupport. The ſtalks will faſten to it, and riſe to a very great height, ſending out roots on every ſide, which get into the joints of walls, or the bark of trees, and thereby are ſupported; or if there is no ſupport near, the ſtalks trail upon the ground, and take root all their length, ſo that they cloſely cover the ſurface, and are difficult to eradicate; for where any ſmall parts of the ſtalks are left, they will ſoon ſpread and multiply. While theſe are fixed to any ſupport, or trail upon the ground, their ſtalks are ſlender and flexible; but when they have reached to the top of their ſupport, they ſhorten and become woody, forming themſelves into large buſhy heads, and their leaves are larger, more of an oval ſhape, and not divided into lobes like the lower leaves, that it hath a different appearance, which has occaſioned ſome to take them for diſtinct ſpecies.

In the latter part of the laſt century, when it was the faſhion to fill gardens with all ſorts of ſheered Ever-greens, there were many of theſe plants trained into round heads, which were clipped into balls, or in form of a cone; and as theſe were ſo hardy as not to be injured by weather, and would grow in any ſoil, ſo they were then much eſteemed; but ſince that unnatural taſte has been exploded, theſe plants are ſeldom admitted into gardens, unleſs to cover walls, or run over grottos, &c. for which purpoſe there is no plant ſo well adapted.

There are two varieties of this, one with ſilver-ſtriped leaves, and the other with yellowiſh leaves on the top of the branches; theſe are preſerved in ſome gardens for the ſake of variety.

Theſe plants are eaſily propagated by their trailing branches, which ſend forth roots their whole length; which branches being cut off, and planted, will grow in almoſt any ſoil or ſituation, and may be trained up to ſtems, or ſuffered to remain as climbers, to cover walls, pales, &c.

They may alſo be propagated by ſeeds, which ſhould be ſown ſoon after they are ripe, which is in the beginning of April: if theſe are kept moiſt and ſhaded, they will grow the ſame ſpring, otherwiſe they will remain a year in the ground; therefore few perſons trouble themſelves to propagate the plants in this way, the other being much more expeditious.

While the ſtalks of this plant trail, either on the ground or upon walls, or other ſupport, they do not produce any flowers, which has occaſioned its being called ſterile, or barren Ivy; but when the branches get above their ſupport, they produce flowers at the end of every ſhoot; theſe appear in September, and are ſucceeded by berries, which turn black before they are ripe, and are formed into round bunches, which are called corymbi, and from theſe the epithet of corymbus, ſo frequently uſed by botaniſts, is taken.

The leaves of this plant are frequently applied to iſſues to keep them cool, and free from inflammations; they are alſo uſed for curing of ſcabs, ſores, and ſcald heads. Mr. Boyle, in his Uſefulneſs of Experimental Philoſophy, commends a large doſe of the full ripe berries, as a remedy againſt the plague; but Schroder ſays, they purge upward and downward. The gum of Ivy is cauſtic, but is recommended by ſome to take ſpots and freckles out of the face.

There is mention made of another ſpecies of Ivy, which is titled Hedera Poetica, by Caſpar Bauhin; this grows in many of the iſlands of the Archipelago, and produces yellow berries; but as I have not ſeen this plant, I cannot determine if it is a diſtinct ſpecies. Dr. Linnæus ſuppoſes it to be only a variety, though he has not ſeen the plant; but Tournefort, who gathered it in the Levant, puts it down as a different ſort.

The ſecond ſort grows naturally in all the northern parts of America; it was firſt brought to Europe from Canada, and has been long cultivated in the Engliſh gardens, chiefly to plant againſt walls, or high buildings to cover them, which theſe plants will do in a ſhort time, for they will ſhoot almoſt twenty feet high in one year, and will mount up to the top of the higheſt building; but as the leaves fall off in autumn, the plants make but an indifferent appearance in winter; and as it is late before they come out in the ſpring, they are not much eſteemed, unleſs it is for ſuch ſituations, where better things will not thrive; for this plant will thrive in the midſt of London, and is not injured by ſmoke, or the cloſeneſs of the air, ſo are very proper for ſuch ſituations. The ſtalks of theſe plants put out roots, which faſten themſelves into the joints of the walls, whereby they are ſupported.

This may be propagated by cuttings, which if planted in autumn on a ſhady border, will take root, and by the following autumn will be fit to plant where they are deſigned to remain.

HEDERA TERRESTRIS. See Glechoma.

HEDGES. Hedges are either planted to make fences round incloſures, or to part off and divide the ſeveral parts of a garden: when they are deſigned as outward fences, they are planted either with Hawthorn, Crabs, or Black Thorn, which is the Sloe; but thoſe Hedges which are planted in gardens, either to ſurround wilderneſs quarters, or to ſcreen the other parts of a garden from ſight, are planted with various ſorts of plants, according to the fancy of the owner; ſome preferring ever-green Hedges, in which caſe the Holly is beſt, next the Yew, then Laurel, Lauruſtinus, Phillyrea, &c. others, who make choice of the deciduous plants, prefer the Beach and Hornbeam, Engliſh Elm, or the Alder, to any other; I ſhall firſt treat of thoſe Hedges which are planted for outſide fences, and afterward briefly touch on the other.

Theſe Hedges are moſt commonly made of Quick, yet it will be proper, before planting, to conſider the nature of the land, and what ſorts of plants will thrive beſt in that ſoil, whether it be clay, gravel, ſand, &c. likewiſe what the ſoil is from whence the plants are to be taken; for if the land they are taken from is much better than that in which they are to be planted, it will be more difficult to get them to grow. As for the ſize, the ſets ought to be about the bigneſs of a gooſe quill, and cut within about four or five inches of the ground; they ſhould be freſh taken up, ſtrait, ſmooth, and well rooted. Thoſe plants which are raiſed in the nurſery, are to be preferred to all others, and if raiſed on a ſpot near the place, it will be beſt.

Secondly, If the Hedge has a ditch, it ſhould be made ſix feet wide at top, and one foot and a half at bottom, and three feet deep, that each ſide may have a proper ſlope; for when the banks are made too upright, they are very ſubject to fall down after every froſt or hard rain; beſides, if the ditches are made narrower, they are ſoon choked up in autumn by the falling leaves, and the growth of weeds, nor are they a ſufficient fence to the Hedge againſt cattle, where they are narrower.

Thirdly, If the bank be without a ditch, the ſets ſhould be ſet in two rows, almoſt perpendicular, at the diſtance of a foot from each other, in the quincunx order, ſo that in effect they will be but ſix inches aſunder.

Fourthly, The turf is to be laid with the Graſs ſide downwards, on that ſide of the ditch the bank is deſigned to be made, and ſome of the beſt mould ſhould be laid upon it, to bed the Quick; then the Quick is to be planted upon it a foot aſunder, ſo that the ends of the Quick may ſtand upright.

Fifthly, When the firſt row of Quick is planted, it muſt be covered with mould, and the turf laid upon it as before; ſo that when the bank is a foot high, you may plant another row of ſets againſt the ſpaces of the lower Quick, and cover them as the former was done; and the bank is to be topped with the bottom of the ditch, and a dry, or dead Hedge laid on the other ſide, to defend the under plantation from the cattle.

In making of theſe dead Hedges, there ſhould be ſtakes driven into the looſe earth, at about two feet and a half diſtance, ſo low as to reach the firm ground.

Oak ſtakes are accounted the beſt, and Black Thorn and Sallow the next; then let the ſmall buſhes be laid at bottom, but not too thick, for that will cauſe the buſhes to rot; but the upper part of the Hedge ſhould be laid with long buſhes to bind the ſtakes in with, by interweaving them.

And, in order to render the Hedge yet ſtronger, you may edder it (as it is called,) i. e. bind the top of the ſtakes in with ſome ſmall long poles, or ſticks on each ſide; and when the eddering is finiſhed, drive the ſtakes anew, becauſe the waving of the Hedge and eddering is apt to looſen the ſtakes.

The Quick muſt be conſtantly kept weeded, and ſecured from being cropped by the cattle, and in February it will be proper to cut it within an inch of the ground, if it was not done before; which will cauſe it to ſhoot ſtrong, and help it much in the growth.

When a Hedge is of about eight or nine years growth, it will be proper to plaſh it; the beſt time for this work is either in October or February.

When a Hedge is grown old, i. e. of about twenty or thirty years growth, and there are in it old ſtubs as well as new ſhoots, the old ſtubs ſhould be cut ſloping off within two or three inches of the ground, and the beſt and longeſt of the middle ſize ſhould be left to lay down; and ſome of the ſtrongeſt, at the height of five or ſix feet, according as you deſign the height of the Hedge to be, may be left to ſerve inſtead of ſtakes, and freſh ſtakes ſhould be put in thoſe places where they are wanting; the Hedge ſhould be then thinned, ſo as to leave on the ſtubs only ſuch ſhoots as are deſigned to be of uſe, that there may be room left to put a ſpade in between them; the ditch alſo ſhould be cleanſed, and each ſide of the ſlopes kept as in a new ditch; and where the earth is waſhed from the roots of the Quick, or is hollow, face it anew with ſo much of the firſt ſpit of earth that is dug out of the ditch, as there is occaſion for, and lay what is dug out at the ſecond ſpit, on the top of the bank; for if it be laid on the ſide, or face of the bank, it will ſlip into the ditch again when wet comes, and alſo take a great deal of the bank along with it.

In plaſhing Quicks, there are two extremes to be avoided; the firſt is, laying it too low and too thick; becauſe it makes the ſap run all into the ſhoots, and leaves the plaſhes without nouriſhment, which, with the thickneſs of the Hedge, kills them.

Secondly, It muſt not be laid too high, becauſe this draws all the ſap into the plaſhes, and ſo cauſes but ſmall ſhoots at the bottom, and makes the Hedge ſo thin, that it will neither hinder the cattle from going through, nor from cropping of it.

When the ſhoot that is deſigned to be plaſhed is bent, give it a ſmall cut with a bill, half through, ſloping a little downwards, and then weave it about the ſtakes; and when the whole is finiſhed, trim off the ſmall ſuperfluous branches that ſtraggle too far out on both ſides of the Hedge.

If the ſtubs are very old, cut them quite down, and ſecure them with good dead Hedges on both ſides, till the young ſhoots are got up tall enough to plaſh, and plant new ſets in the void ſpaces.

In making a Hedge, if it be ſet with Crab Stocks, it will be proper to leave one ſtanding uncut up at every thirty or forty feet, if the ground on both ſides of the Hedge be your own; which being done, they may be ſo ordered, by pruning or ſtaking, that one may lean into one ground, and the other into another, &c.

Theſe ſtocks ſhould be pruned up every year, till they are brought out of the reach of the cattle, and then they may be grafted with the Red Streak, Gennetmoil, or what other kind of cyder Apple you pleaſe.

If the ſtocks be of Apple kernels, they may ſtand ungrafted, for many of them will yield very good cyder fruit; but then ſuch ſtocks as are not grafted, will be longer before they bear; and alſo when you do graft, you may be certain of your kind; but if you find a very natural ſtock, which by leaf, ſhoot, and bud, appears likely, you may try it, and ſo you may have a new fine fruit; and if you do not like it, you may graft it when you pleaſe.

As for the reſt of the Hedge, when it has ſhot four or five years, you may lay it to make a fence for the doing of which, take the following directions:

Firſt, At every laying to lay down ſome old plaſhes; or, if the Hedge be thin, young ones; but they muſt be ſo laid, as to point with their ends to the ditch ſide of the bank, the ends being kept low on the bank; by being ſo ordered, they will the better thicken the bottom of the Hedge, and keep up the earth of the bank.

Secondly, To heighten the bank every time you lay earth on it, ſo as to cover the layers, all but the ends, this earth will very much help the Quick; and by heightening the banks, and deepening the ditch, you will render the fence the better.

Thirdly, Not to cut the plaſhes too much, but juſt ſo as they may bend down well; nor to lay them too upright, as ſome do, but to lay them near to a level; for by ſo doing, the ſap will the better break out at ſeveral places, and not run ſo much to the ends, as it will when they lie too much upon the ſlope.

If you have much wood to ſpare, you may cut up great part of thoſe that grow near the ditch, but then you ought to hang the bank with buſhes, to prevent cattle from cropping them the firſt year; theſe will ſhoot ſtrong, ſecure the Hedge, keep up the bank, and thicken the bottom of the Hedge.

Fourthly, Take care to lay the Hedge pretty thick, and turn the beard on the ditch ſide; but you muſt not let the beard hang uncut (though it makes a good ſhew at the firſt making), but you muſt cut off all the ſtraggling boughs within half a foot of the Hedge on both ſides, which will cauſe it to ſhoot ſtrong at theſe places, and make the Hedge much the thicker.

Fifthly, If the bank be high, make the Hedge ſo low, that it may juſt ſerve for a fence the firſt year, for it will ſoon grow higher; and the lower the Hedge is made, the faſter the Quick will grow, and alſo will be the thicker at the bottom; but care muſt be taken to preſerve it from cattle on the field ſide for the two firſt years that it is made.

Sixthly, If you would have a good Hedge, or fence, you ſhould new lay it once in fourteen or fifteen years, and conſtantly root out Elder, Travellers Joy (which ſome call Bull-bine), Briony, &c. and do not leave too many high ſtandards, or pollards in it, though the Elm is one of the beſt; alſo no dead wood is to be left in the bottom of the Hedges, for that will choke the Quick; but if there be a gap, the dead Hedge ſhould be made at a diſtance.

The Crab is alſo frequently planted for Hedges, and if the plants are raiſed from the kernels of the ſmall wild Crab, they are much to be preferred to thoſe which are raiſed from kernels of all ſorts of Apples without diſtinction; becauſe the plants of the true ſmall Crab never ſhoot ſo ſtrong as thoſe of the Apples, ſo may be better kept within the proper compaſs of a Hedge; and as they have generally more thorns upon them, they are better guarded againſt cattle, &c. than the other; beſides, the plants of the Crab will grow more equal than thoſe which are raiſed from the kernels of various kinds of Apples, for theſe always produce a variety of plants, which differ from each other in their manner of growth, as much as in the ſize and flavour of their fruits; ſo that Hedges made of theſe will not appear ſo well, nor can be ſo well managed as the other.

Some perſons intermix Crab with the White Thorn in their Hedges, but this is not a good method; for the plants of the Crab will grow much ſtronger than thoſe of the White Thorn, ſo that the Hedge will not be of equal growth; which is not near ſo beautiful or uſeful, as when the plants of a Hedge keep pace in their growth.

The Black Thorn, or Sloe, is alſo frequently planted for Hedges, and is a ſtrong durable plant for that purpoſe, eſpecially as it is ſo ſtrongly armed with thorns, that cattle ſeldom care to brouze upon it; but where this is planted, the beſt way is to raiſe the plants from the ſtones of the fruit; for all thoſe which are taken from the roots of old trees, ſpawn, and put out ſuckers in ſuch plenty from their roots, as to ſpread over, and fill the neighbouring ground to a conſiderable diſtance on each ſide of the Hedge; and this plenty of ſuckers drawing away the nouriſhment from the old plants of the Hedge, they never grow ſo well as where there are few or no ſuckers produced, which thoſe plants which are propagated from the ſtones ſend not forth, or at leaſt but ſparingly, therefore may with little trouble be kept clear of them. The beſt method of raiſing theſe Hedges is, to ſow the ſtones in the place where the Hedge is intended (where it can be conveniently done), for then the plants will make a much greater progreſs than thoſe which are tranſplanted; but the objection to this method will ariſe from the difficulty of ſecuring the young plants from the cattle; but this can have little force, when it muſt be conſidered, that if the Hedge is planted, it muſt be fenced for ſome years, to prevent the cattle from deſtroying it; therefore the ſame fence will do for it when ſown, nor will this require a fence much longer than the other. For the plants which ſtand unremoved, will make a better fence in ſeven years, than that which is planted, though the plants ſhould be of three or four years growth when planted; which is what I have ſeen two or three times, where the experiment has been tried. The ſtones of this fruit ſhould be ſown early in January, if the weather will permit; but when they are kept out of the ground longer, it will be proper to mix them with ſand, and keep them in a cool place. The buſhes of the Black Thorn are by much the beſt of any for making of dead Hedges, being of longer duration, and having many thorns, neither the cattle nor the Hedge-breakers, will care to meddle with them; theſe buſhes are alſo the beſt to be uſed for under ground drains, for the draining of land, for they will remain ſound a long time when the air is excluded from them.

The Holly is ſometimes planted for Hedges, and is a very durable ſtrong fence; but where it is expoſed, there will be great difficulty to prevent its being deſtroyed, otherwiſe it is by far the moſt beautiful plant, and being an Evergreen, will afford much better ſhelter to cattle in winter, than any other ſort of Hedge; and the leaves being armed with thorns, the cattle will not care to brouze upon it. Another objection to this plant is the ſlow growth, ſo that Hedges planted with this plant, require to be fenced a much longer time than moſt others. This is a reaſon which muſt be admitted, to prevent this being generally practiſed; but in ſuch grounds as lie contiguous to, or in ſight of gentlemen's houſes, theſe ſort of Hedges will have an exceeding good effect, eſpecially when they are well kept, as they will appear beautiful at all ſeaſons of the year; and in the ſpring of the year, when the ſharp winds render it unpleaſant to walk abroad in expoſed places, theſe Hedges will afford good ſhelter, as they will effectually keep off the cold winds, if they are kept cloſe and thick. The ſureſt method of raiſing theſe Hedges is, by ſowing the berries in the place where they are to ſtand; but theſe berries ſhould be buried in the ground one year before they are ſown, by which method they will be prepared to grow the following ſpring. The way of doing this is, to gather the berries about Chriſtmas (which is the time they are uſually ripe,) and put them into large flower-pots, mixing ſome ſand with them; then dig holes in the ground, into which the pots muſt be ſunk, covering them over with earth about ten inches thick; in this place they may remain till the following October, when they ſhould be taken up, and ſown in the place where the Hedge is intended. The ground for this Hedge ſhould be well trenched, and cleared from the roots of all bad weeds, buſhes, trees, &c. Then two drills ſhould be made at about a foot diſtance from each other, and about two inches deep, into which the ſeeds ſhould be ſcattered pretty cloſe, leſt ſome ſhould fail; for it is better to have too many plants come up, than to want. The reaſon of my adviſing two drills is, that the Hedge may be thick to the bottom, which in a ſingle row rarely happens, eſpecially if there is not great care taken of them in the beginning. When the plants come up, they muſt be carefully weeded; for if the weeds are permitted to grow among them, they will ſoon deſtroy them, or weaken them ſo much, that they will not recover their ſtrength in a long time. This ſhould be conſtantly obſerved, by every perſon who is deſirous to have good Hedges of either ſort; for when the weeds are ſuffered to grow near the plants, they will not only rob them of a great part of their nouriſhment, but alſo prevent their putting out ſhoots near the ground, which will occaſion the bottom of the Hedge to be thin and naked.

When theſe Holly Hedges are deſigned to be kept very neat, they ſhould be ſheered twice a year, in May and Auguſt; but if they are only deſigned as fences, they need not be ſheered oftener than once a year, which ſhould be about the latter end of June, or the beginning of July; and if this is well performed, the Hedges may be kept very beautiful.

The fences which are made to ſecure theſe Hedges from cattle while they are young, ſhould be contrived ſo as to admit as much free air as poſſible, which is abſolutely neceſſary for the growth of the plants; for when they are crowded on each ſide with dead Hedges, the plants ſeldom thrive well. The beſt ſort of fences for this purpoſe, are thoſe which are made with poſts and rails; or inſtead of rails, three ropes drawn from poſt to poſt, and holes made in the poſts to draw the ropes through; this is the cheapeſt fence of this kind, and will appear very handſome; but if ſheep are not admitted into the fields, there will be occaſion for two ropes only, which will be enough to keep off larger cattle; and if the ropes are painted over with a compoſition of melted pitch, brown Spaniſh colour, and oil, mixed well together, they will laſt ſound ſeveral years; and theſe ſort of fences never obſtruct the air, and the place, at the ſame time being open to view, the weeds will be better diſcovered than when the fences are cloſe. In the latter caſe, the Hedges are ſometimes ſuffered to be over-run with weeds, by their being excluded from the ſight, ſo are frequently forgotten, eſpecially in moiſt weather, when the weeds grow more luxuriant.

There are ſome perſons who intermix Holly with the White Thorn in making their Hedges, which if rightly managed, will have a good effect, eſpecially when young; but when this is practiſed, the Holly ſhould be planted ſo near, as that the Hedge may be entirely formed of it as it grows up, when the White Thorn ſhould be quite rooted out; for as theſe advance, they will not keep pace in their growth, ſo will not appear beautiful when intermixed.

When a Hedge of Holly is intended to be made by plants, the ground ſhould be well trenched, as was before adviſed for the ſeeds; and (unleſs the ground be very wet) the plants ſhould be ſet in October, but, in wet ground, March is preferable. The plants ſhould not be taken from a better ſoil than that in which they are to be planted; for when it ſo happens, the plants are much longer before they recover this change, than thoſe are which are taken from a leaner ſoil. If the plants have been before removed two or three times, they will have better roots, and will be in leſs danger of miſcarrying; beſides, they may be removed with balls of earth to their roots. When the froſt comes on, if mulch be laid upon the ground near the roots of the plants, it will prevent the tender fibres, which may then have been put out, from being deſtroyed by the cold. I would never adviſe the planting of Hedges with Holly plants, of above five or ſix years growth from the berries; for when the plants are older, if they take to grow, they are longer before they form a good Hedge, than plants which are much younger; and if the plants have been twice before tranſplanted, they will more certainly grow.

I ſhall next treat of Hedges for ornaments in gardens: theſe are ſometimes planted with Evergreens, eſpecially if they are not intended to grow very high; in which caſe, they are planted with deciduous trees. Evergreen Hedges are planted with Holly, Yew, Laurel, Lauruſtinus, Phillyrea, Alaternus, evergreen Oak, and ſome others of leſs note. The Holly is preferable to any other, for the reaſons before given. Next to this, moſt people prefer the Yew, on account of its growing very cloſe; for when theſe Hedges are well kept, they will be ſo thick as that a bird cannot get through them; but the dead colour of the Yew, renders theſe Hedges leſs agreeable. The Laurel is one of the moſt beautiful greens of any of the evergreen trees, but then it ſhoots ſo luxuriant, as to render it difficult to keep the Hedges which are planted with it, in tolerable ſhape; beſides, the leaves being very large, if the Hedge is clipped with ſheers, the leaves will be cut through, which gives them a bad appearance; therefore where there are Hedges of this kind, it will be the beſt way to prune them with a knife, cutting the ſhoots juſt down to a leaf. And although by this method the Hedge cannot be rendered ſo even as when cut with ſheers, yet it will have a much better appearance than that of moſt of the leaves being cut through and ſtubbed, in the manner they muſt be when ſheered.

The Lauruſtinus is alſo a very fine plant for this purpoſe, but the ſame objection is to be made to this as hath been to the Laurel; and as one of the great beauties of this plant is in its flowers, which are produced in the winter and ſpring, ſo when theſe are ſheered, the flowers are generally cut off, by which their beauty is loſt. Nor can this be avoided, where the Hedge is to be kept in cloſe order, therefore this plant is not ſo proper for the purpoſe; but in ſuch places where walls or other fences are deſigned to be hid, there is not any plant better adapted than this, provided it is rightly managed; for the branches of this plant are ſlender and pliable, ſo may be trained up cloſe to the fence, whereby it may be entirely covered; and if, inſtead of clipping theſe with ſheers, they are pruned with a knife, they may be ſo managed, as to have them full of flowers from the ground upward. This may be effected by pruning them in April, when the flowers are going off, cutting out thoſe ſhoots that have flowered, or project too far from the fence; always cutting cloſe to the leaf, that no ſtubs may be left: but thoſe new ſhoots of the ſame ſpring muſt by no means be ſhortened, becauſe the flowers are always produced at the extremity of the ſhoots of the ſame year; therefore when theſe are topped, as they muſt be by ſheering, there can be few or no flowers upon theſe plants, except toward the top, where the ſheers have not paſſed. By this method of knife pruning, the leaves will alſo be preſerved entire, and the Hedge may always be kept enough within compaſs; and ſo thick, as fully to anſwer the purpoſe of covering the fence; and by the ſhoots growing a little irregular, it will make a much better appearance than any ſhorn Hedge whatever.

The ſmall leaved and the rough leaved Lauruſtinus are the beſt ſorts for this purpoſe, becauſe their branches grow cloſer together than thoſe of the ſhining leaved; they are alſo more hardy, and flower much better than the other, when growing in the open air.

The True Phillyrea is the next beſt plant for Hedges; it is by the gardeners called the True Phillyrea, to diſtinguiſh it from the Alaternus, which they ſimply call the Phillyrea. The branches of this are ſtrong, the leaves pretty large, and of a ſtrong green colour. And as this is a plant of middling growth, the Hedges planted with this may be led up to the height of ten or twelve feet; and if theſe Hedges are kept narrow at the top, that there may not be too much width for the ſnow to lodge upon them, they may be rendered very cloſe and thick, and being a very good green, will make a fine appearance.

The Alaternus was formerly much more cultivated in the Engliſh gardens than at preſent. This was often planted to form Hedges, but the branches of this plant are too pliant for this purpoſe, being frequently diſplaced by ſtrong winds, which render theſe Hedges unſightly; they alſo ſhoot very irregular and thin, ſo that the middle of the Hedge is frequently open and wide, and only the ſides of them can be kept tolerably cloſe, and that muſt be by often clipping them. If we add to this, their being frequently laid or broken down by ſnow in the winter, it muſt be deemed an improper plant for this purpoſe.

The Ilex, or evergreen Oak, is alſo planted for Hedges, and where theſe are deſigned to grow pretty tall, it is a fit plant for the purpoſe; becauſe it is a plant of large growth, eſpecially the ſort which is moſt common in England; for there are two ſorts of them which grow in the ſouth of France and Italy, that are of much humbler growth, ſo are better adopted to this purpoſe, eſpecially where the Hedge is not intended to be high, but theſe are not at preſent common here. When theſe Hedges are planted very young, and kept cloſe trained from the beginning, they may be very cloſe from the ground to the height of twenty feet or more; but theſe muſt always be kept narrower at the top than below, that there may not too much ſnow lodge upon them in the winter, which is apt to break and diſplace the branches, whereby the Hedges will be rendered unſightly.

There are alſo ſome perſons who have planted the Pyracantha, or evergreen Thorn, Juniper, Box, Cedar of Virginia, Bay, &c. as alſo the Halimus, or Sea Purſlane, and the Furz, Roſemary, and ſeveral other plants for Hedges; but the five ſorts firſt mentioned having very pliant branches, which will require to be ſupported, and the three laſt being often deſtroyed by ſevere froſt, renders them unfit for this purpoſe; nor are there other ſorts of evergreen plants in the Engliſh gardens, which are ſo well adapted for Hedges, as thoſe before-mentioned,

The deciduous trees, which are uſually planted to form Hedges in gardens, are the following ſorts.

The Hornbeam is much eſteemed for this purpoſe, eſpecially in ſuch places where they are not required to be very high, or not wanted to grow very faſt; for this plant, while young, doth not make ſo great progreſs as many others; but as it is of ſlower growth, the Hedges may be kept neat with leſs trouble than moſt other plants will require; and the branches naturally growing very cloſe, they will make one of the cloſeſt Hedges of all the deciduous trees; but as the leaves of this tree continue upon the branches all the winter, and until the buds in the ſpring force them off, they have a bad appearance during the winter ſeaſon.

The Beech is alſo a very proper tree for this purpoſe, having the ſame good qualities as the Hornbeam; but the leaves of this continue late in winter upon the branches, when they will have a bad appearance; beſides, the litter which is occaſioned by their leaves gradually falling moſt part of the winter, prevents the garden from being made clean a great while longer than if there are none of theſe trees planted.

The ſmall-leaved Engliſh Elm, is alſo a proper tree for tall Hedges; if theſe are planted young, and kept cloſely clipped from their firſt ſetting out, the Hedges may be trained up to the height of thirty or forty feet, and be very cloſe and thick the whole height. But when theſe trees are planted for this purpoſe, they ſhould not be crowded ſo cloſe together as they uſually are by moſt people; by which method, when the trees have ſtood ſome years, if they have thriven well, their ſtems will approach ſo near each other, as that few branches can be maintained below, whereby the bottom of the Hedge will be naked; therefore they ſhould not be planted cloſer together than ſeven or eight feet, or if they are ten feet it will be ſtill better. And although at this diſtance they will not form a cloſe Hedge ſo ſoon as when the trees are planted cloſer together, yet they will in a few years recompenſe for that, by their growing much cloſer and better from the ground upward.

The Dutch Elm was formerly in great eſteem for Hedges, being quick of growth, and thriving in ſuch ſoils as the Engliſh Elm would not grow; but the wretched appearance which theſe Hedges made, after they had been growing a few years, very juſtly occaſioned their being almoſt univerſally rooted out of gardens, for a more abominable plant was never introduced into gardens than this.

The Lime-tree hath alſo been recommended for Hedges, and in ſome of the old gardens there were many planted with this tree, which, for a few years after planting, made a tolerable appearance, eſpecially when they grow upon a moiſt ſoil; but after they had ſtood ſome years, they grew very thin at bottom, and by being ſheered at the top, they were rendered very ſtubby and unſightly, their leaves growing very thinly upon the branches, and theſe frequently turning of a black diſagreeable colour, and falling off very ſoon in the autumn, and ſometimes in the ſummer in dry ſeaſons, has brought theſe trees ſo much into diſrepute, as that few perſons make uſe of them at preſent for this purpoſe: nor ſhould any of the very ſtrong ſhooting trees be applied to this uſe; for the more they are cut, the ſtronger they will ſhoot, and of courſe will appear very unſightly; beſides, the often cutting of theſe Hedges occaſions great trouble and expence, and frequent litters in gardens.

The Alder is frequently planted for Hedges, and where the ſoil is moiſt, there is not any of the deciduous trees equal to it for this purpoſe; for the leaves are of a lively green, continuing freſh till late in the autumn; and when they decay, their litter is ſoon over, for they all drop in a ſhort time.

There are, beſides the trees before-mentioned, many of the flowering ſhrubs which have been planted to form Hedges; ſuch as Roſes, Honeyſuckles, Sweetbriar, &c. but theſe make a bad appearance, being more difficult to train; and if they are cut to keep them within compaſs, their flowers, which are their greateſt beauty, will be entirely deſtroyed. But as theſe are but of low growth, they are not proper to plant where the Hedges are to be of any height.

Although I have given theſe full directions for planting and ordering of theſe Hedges for the pleaſure-garden, yet I am far from recommending them as ornamental or uſeful. But as there are numbers of perſons who may differ from me in their opinion, and therefore might think it a deficiency in my book, had I not given theſe inſtructions; to avoid their reproach, I have inſerted as much as I think will be neceſſary for the obtaining theſe Hedges wherever they are deſired, and at a leſs expence than the late method of planting them hath been generally attended with; where it is not uncommon to ſee four times the number of trees planted in theſe Hedges as would have been neceſſary, or that can remain long cloſe together with any beauty. But moſt people who plant, are in too great a hurry to have their garden filled; and therefore frequently plant ſo cloſe, as that in three or four years (if their trees thrive) three-fourths of them will require to be taken away again, to make room for thoſe which are left to grow; and there are not wanting perſons, who are ready enough to encourage this practice, ſince their own intereſt is thereby promoted.

The taſte in gardening having been greatly altered of late years for the better, theſe clipped Hedges have been almoſt excluded; and it is to be hoped, that a little time will entirely baniſh them out of the Engliſh gardens, as it has already been done by the ſhorn Evergreens, which, a few years ſince, were eſteemed the greateſt beauties of gardens. The latter was introduced by the Dutch gardeners, and that of tall Hedges with treillage-work, was in imitation of the French gardens; in ſome of which, the expence of the iron treillage, to ſupport the trees which compoſe their cabinets, pavillions, bowers, porticoes, and other pieces of rural architecture, amounted to a very great ſum. I have been informed this work, in one garden, has coſt above twenty thouſand crowns; and this only to train up trees in the diſtorted ſhape of pilaſters, niches, cornices, pediments, &c. when at the ſame time, theſe can no longer retain the forms intended, than they are kept cloſely ſhorn into them; for no ſooner do the trees begin to make freſh ſhoots, but the whole frame is altered; and inſtead of carrying the fine finiſhed appearance of a regular piece of architecture, it is grown into a rude unpoliſhed form. This expenſive ſort of work never has made much progreſs in England, but that part of the French taſte, in ſurrounding all the ſeveral diviſions of gardens with tall clipped Hedges, making great alleys, forming the walks into ſtars, and the like ſtiff performances, have too much obtained for ſome years paſt in England: and the taller theſe clipped Hedges were, the more they were admired; though many times they ſhut out from the view the ſight of ſome of the nobleſt Oaks, and other timber trees, growing in the quarters, which are infinitely more pleaſing to a perſon of true taſte, than all the ridiculous forms it is poſſible for trees to be framed in by art. Beſides, when the expence of keeping theſe Hedges, together with the great litter they occaſion when clipped, is conſidered, theſe, added to many other reaſons which might be given, are ſufficient to exclude them out of gardens; where they can never be eſteemed neceſſary, but to ſhut out from the view the ſight of worſe objects.

HEDYPNOIS. See HYOSERIS.

HEDYSARUM. Lin. Gen. Plant. 793. Tourn. Inſt. R. H. 401. tab. 225. French *Honeyſuckle.*

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, cut into five ſegments at the top. It is of the butterfly kind, having an oblong compreſſed ſtandard, which is indented at the point and reflexed; the wings are oblong and narrow; the keel is compreſſed, broader at the end, but convex at the baſe. It hath nine ſtamina joined, and one ſtanding ſeparate, which are terminated by roundiſh compreſſed ſummits; the ſtamina are reflexed, having an angle or knee. In the center is ſituated a long narrow germen, ſupporting an awl-ſhaped inflexed ſtyle, crowned by a ſingle ſtigma. The germen afterward becomes a jointed pod which is compreſſed, each joint being roundiſh, and incloſes a ſingle kidney-ſhaped ſeed.

This genus of plants is ranged in the third ſection of Linnæus's ſeventeenth claſs, intitled Diadelphia Decandria, which includes thoſe plants whoſe flowers have ten ſtamina joined in two bodies.

The SPECIES are,

1. HEDYSARUM (*Coronarium*) foliis pinnatis, leguminibus articulatis aculeatis, nudis, rectis, caule diffuſo. Hort. Cliff. 365. *French Honeyſuckle with winged leaves, naked, prickly, jointed pods, and a diffuſed ſtalk.* Hedyſarum clypeatum, flore ſuaviter rubente. H. Eyſt. *French Honeyſuckle, with a delicate red flower.*
2. HEDYSARUM (*Spinoſiſſimum*) foliis pinnatis, leguminibus articulatis, aculeatis tomentoſis, caule diffuſo. Hort. Upſal. 231. *French Honeyſuckle with winged leaves, jointed, prickly, woolly pods, and a diffuſed ſtalk.* Hedyſarum clypeatum minus, flore purpureo. Raii Hiſt. *Smaller French Honeyſuckle with a purple flower.*
3. HEDYSARUM (*Canadenſe*) foliis ſimplicibus ternatiſque, floribus racemoſis. Hort. Cliff. 232. *French Honeyſuckle with ſingle and trifoliate leaves, and flowers in bunches.* Hedyſarum triphyllum Canadenſe. Cornut. *Three-leaved French Honeyſuckle of Canada.*
4. HEDYSARUM (*flexuoſum*) foliis pinnatis, leguminibus articulatis, aculeatis, flexuoſis, caule diffuſo. Lin. Sp. Plant. 750. *French Honeyſuckle with winged leaves, jointed prickly pods which are waved, and a diffuſed ſtalk.* Hedyſarum annuum, ſiliquâ aſperâ undulatâ intortâ. Tourn. *Annual French Honeyſuckle, with a rough, waved, writhed pod.*
5. HEDYSARUM (*Diphyllum*) foliis binatis petiolatis, floralibus ſeſſilibus. Flor. Zeyl. 291. *French Honeyſuckle with two leaves upon a foot-ſtalk, ſitting cloſe to the ſtalks.* Hedyſarum minus diphyllum, flore luteo. Sloan. Cat. 73. *Smaller two-leaved French Honeyſuckle, with a yellow flower.*
6. HEDYSARUM (*Purpureum*) foliis ternatis, foliolis obovatis floribus paniculatis terminalibus, leguminibus intortis. *French Honeyſuckle with trifoliate oval leaves, flowers growing in panicles at the ends of the ſtalks, and intorted pods.* Hedyſarum triphyllum fruticoſum, flore purpureo, ſiliquâ varie diſtortâ. Sloan. Cat. 73. *Three-leaved ſhrubby French Honeyſuckle, with a purple flower and a variouſly diſtorted pod.*
7. HEDYSARUM (*Caneſcens*) foliis ternatis ſubtus nervoſis, caule glabro fruticoſo floribus ſpicatis terminalibus. *Three-leaved ſhrubby dwarf Honeyſuckle, with veins on the under ſide, a ſmooth ſhrubby ſtalk, with flowers growing in ſpikes at the ends.* Hedyſarum triphyllum fruticoſum ſupinum, flore purpureo. Sloan. Cat. *Three-leaved ſhrubby dwarf French Honeyſuckle, with a purple flower.*
8. HEDYSARUM (*Sericeum*) foliis ternatis, foliolis ovatis ſubtus ſericeis, floribus ſpicatis alaribus terminalibuſque. *Three-leaved French Honeyſuckle, with oval leaves ſitting on their under ſide, and flowers in ſpikes from the ſide and the end of the ſtalks.* Hedyſarum triphyllum fruteſcens, foliis ſubrotundis & ſubtus ſericeis, flore purpureo. Houſt. *Three-leaved ſhrubby French Honeyſuckle with roundiſh leaves, which are ſilky underneath, and a purple flower.*
9. HEDYSARUM. (*Villoſum*) foliis ternatis, caulibus diffuſis villoſis, floribus ſpicatis terminalibus, calycibus, villoſiſſimis. *Three-leaved French Honeyſuckle, with diffuſed ſtalks which are hairy, flowers growing in ſpikes at the ends of the branches, and very hairy empalements.* Hedyſarum triphyllum humile, flore conglomerato calyce villoſo. Houſt. *Dwarf three-leaved French Honeyſuckle, with flowers growing in cluſters, and a hairy cup.*
10. HEDYSARUM (*Procumbens*) foliis ternatis caulibus procumbentibus racemoſis, floribus laxè ſpicatis terminalibus, leguminibus contortis articulis quadrangularibus. *Three-leaved French Honeyſuckle, with branching trailing ſtalks, flowers growing in looſe ſpikes at the ends of the branches, and twiſted pods with ſquare joints.* Hedyſarum triphyllum procumbens, foliis rotundioribus & minoribus, ſiliquis tenuibus & intortis. Houſt. *Trailing three-leaved French Honeyſuckle, with ſmaller and rounder leaves, and narrow contorted pods.*
11. HEDYSARUM (*Intortum*) foliis ternatis, foliolis obcordatis, caule erecto triangulo villoſo, racemis terminalibus, leguminibus articulatis incurvis. *French Honeyſuckle, with trifoliate leaves whoſe lobes are heart-ſhaped, a triangular upright hairy ſtalk, flowers growing in long bunches at the ends of the branches, and and jointed incurved pods.* Hedyſarum triphyllum, caule triangulari, foliis mucronatis, ſiliquis tenuibus intortis. Houſt. *Three-leaved French Honeyſuckle, with a triangular ſtalk, pointed leaves, and a narrow contorted pod.*
12. HEDYSARUM (*Glabrum*) foliis ternatis obcordatis, caule paniculato, leguminibus monoſpermis glabris. *French Honeyſuckle with trifoliate heart-ſhaped leaves, a paniculated ſtalk, and ſmooth pods containing one ſeed.* Hedyſarum triphyllum, annuum, erectum, ſiliquis intortis, & ad extremitatem amplioribus. Houſt. *Three-leaved, annual, upright French Honeyſuckle, with contorted pods, which are broad at their extremity.*
13. HEDYSARUM (*Scandens*) foliis ternatis, foliolis obversè-ovatis, caule volubili, ſpicâ longiſſimâ reflexâ. *Three-leaved French Honeyſuckle, with obverſe oval lobes, a twining ſtalk, and a very long reflexed ſpike of flowers.* Hedyſarum triphyllum Americanum ſcandens, flore purpureo. *Three-leaved, climbing, American French Honeyſuckle, with a purple flower.*
14. HEDYSARUM (*Repens*) foliis ternatis obcordatis, caulibus procumbentibus racemis lateralibus. Lin. Sp. 1056. *Three-leaved French Honeyſuckle, with oval heart-ſhaped leaves, trailing hairy ſtalks, and flowers on the ſide of the ſtalks.* Hedyſarum procumbens, trifolii fragiferi folio. Hort. Elth. 172. *Trailing French Honeyſuckle, with leaves like the Strawberry Trefoil.*
15. HEDYSARUM (*Maculatum*) foliis ſimplicibus ovatis obtuſis. Hort. Cliff. 449. *French Honeyſuckle, with oval, obtuſe, ſingle leaves.* Hedyſarum humile, capparidis folio maculato. Hort. Elth. 170. *Low French Honeyſuckle, with a ſpotted Caper leaf.*
16. HEDYSARUM (*Fruteſcens*) foliis ternatis ovato-lanceolatis, ſubtus villoſis, caule fruteſcente villoſo.

Trifoliate French Honeyſuckle, with oval ſpear-ſhaped leaves, hairy on their under ſide, and a ſhrubby hairy ſtalk. Quere, Whether this be not the Hedyſarum foliis ternatis ſub-ovatis ſubtus villoſis caule fruteſcente. Flor. Virg. 174. *Three-leaved French Honeyſuckle, with oval leaves and a ſhrubby ſtalk.*

17. HEDYSARUM (*Pedunculatum*) foliis ternatis, foliolo intermedio pediculo longiore, racemis alaribus erectis longiſſimis. *French Honeyſuckle with trifoliate leaves, the middle lobe ſtanding on a longer foot-ſtalk, and very long bunches of flowers coming from the ſides of the ſtalks.*

18. HEDYSARUM (*Alhagi*) foliis ſimplicibus lanceolatis obtuſis, caule fruticoſo ſpinoſo. Lin. Sp. Plant. 745. *French Honeyſuckle with ſingle, ſpear-ſhaped, obtuſe leaves, and a prickly ſhrubby ſtalk.* Alhagi Maurorum. Rauwolf. 94. *The Albagi of the Moors.*

19. HEDYSARUM (*Triquetrum*) foliis ſimplicibus cordato-oblongis integerrimis glabris. *French Honeyſuckle with ſingle, oblong, heart-ſhaped leaves, which are ſmooth and entire.* Onobrychis Zeylanica aurantii folio. Pet. Hort. Scic. 247. *Cockſhead of Ceylon with an Orange-leaf.*

20. HEDYSARUM (*Echaſtaphyllum*) foliis ſimplicibus ovatis ſubtus ſericeis, petiolis muticis. Amœn. Acad. 5. p. 403. *French Honeyſuckle with oval ſingle leaves, ſilky on their under ſide, and a ſpiked foot-ſtalk.* Spartium ſcandens, citri foliis, floribus albis ad nodos conſertim naſcentibus. Plum. Sp. 19.

21. HEDYSARUM (*Gangeticum*) foliis ſimplicibus ovatis acuminatis, ſpicis longiſſimis nudis terminalibus. *French Honeyſuckle with oval-pointed ſingle leaves, and very long naked ſpikes of flowers terminating the ſtalks.* An Hedyſarum foliis ſimplicibus ovatis acutis baſi ſtipulatis. Lin. Sp. 1052.

The firſt ſort has been long cultivated in the Engliſh gardens for ornament. This grows naturally in Italy; there are two varieties of this, one with a bright red, and the other a white flower, which very rarely vary from one to the other; but as there is no other difference but in the colour of their flowers, ſo they are ſuppoſed to be the ſame ſpecies.

It is a biennial plant, which flowers the ſecond year, and ſoon after the ſeeds are ripe, the roots generally periſh: this ſends up ſeveral hollow ſmooth ſtalks two or three foot long, which branch out on each ſide, garniſhed with winged leaves, compoſed of five or ſix pair of oval lobes, terminated by an odd one; the leaves are placed alternate, and from their baſe comes out foot-ſtalks which are five or ſix inches long, ſuſtaining ſpikes of beautiful red flowers; theſe are ſucceeded by compreſſed jointed pods, which are very rough, ſtanding erect; in each of the joints is lodged one kidney-ſhaped ſeed. This ſort flowers in June and July, and the ſeeds ripen in September. The white is only a variety of this, and as ſuch, is ſometimes preſerved in gardens.

They are propagated by ſowing their ſeeds in April, in a bed of light freſh earth; and when the plants come up, they ſhould be tranſplanted into other beds of the like earth, and in an open ſituation, at about ſix or eight inches diſtance from each other, leaving a path between every four rows, to go between them to hoe, and clear them from weeds. In theſe beds they may remain until Michaelmas, then may be tranſplanted into the large borders of a parterre or pleaſure-garden, allowing them at leaſt three feet diſtance from other plants, amongſt which they ſhould be interſperſed, to continue the ſucceſſion of flowers; where they will make a fine appearance when blown, eſpecially the red ſort, which produces very beautiful flowers.

As theſe plants decay after they have perfected their ſeeds, ſo there ſhould annually be a freſh ſupply of plants raiſed, where they are deſired, for the old roots ſeldom continue longer. They are very proper ornaments for large borders, or to fill up vacancies among ſhrubs, but they grow too large for ſmall borders, unleſs their ſtalks are pruned off, leaving only two or three on each plant; which, if kept upright with ſticks, will prevent their hainging over other flowers. They are propagated for ſupplying the markets with plants to adorn the London gardens and balconies, by the gardeners in the neighbourhood of London.

The ſecond ſort is an annual plant, which grows naturally in Spain and Portugal; the leaves of this are narrow and oblong, four or five pair being placed along the midrib, with an odd one at the end; the ſtalks are terminated by ſmall ſpikes of purple flowers, which are ſucceeded by ſmall rough pods, ſhaped like thoſe of the former ſort. This plant is preſerved in botanic gardens for the ſake of variety; it is propagated by ſeeds, which ſhould be ſown the beginning of April, in the place where the plants are to remain, and will require no other culture but to thin them where they are too near, and keep them clean from weeds. This flowers in July, and the ſeeds ripen in autumn.

The third ſort hath a perennial root, which will abide many years if planted in a dry ſoil. This is propagated by ſowing the ſeeds in the manner directed for the former; but when the plants are come up two inches high, they ſhould be tranſplanted where they are to remain for good; but if they are not too thick in the ſeed-bed, they may be ſuffered to remain there until the following autumn; at which time they ſhould be carefully taken up, and tranſplanted into the borders where they are deſigned to ſtand; for their roots generally run down very deep, ſo that it is not ſafe to remove them often. This plant produces its flowers about the ſame time of the year as the former, and if the ſeaſon proves favourable, perfects its ſeeds in autumn; and the roots will abide in the open air very well, reſiſting the ſevereſt cold, provided they are planted in a dry ſoil.

The fourth ſort is an annual plant, which grows naturally in the Levant. This hath ſome reſemblance of the firſt, but is much ſmaller; the ſtalks ariſe near a foot high, and are garniſhed with winged leaves, compoſed of two or three pair of oval lobes, terminated by an odd one; the flowers come out in ſpikes at the top of the ſtalks, which are of a pale red intermixed, with a little blue. Theſe appear in July, and are ſucceeded by jointed pods which are waved on both ſides, forming an obtuſe angle at each joint; the ſeeds ripen in the autumn. This is propagated in the ſame way as the ſecond ſort, and is equally hardy.

The fifth ſort grows naturally in both Indies; the ſeeds of this were ſent me from La Vera Cruz, by the late Dr. Houſtoun. This is an annual plant, with a long tap root which runs deep in the ground, ſending out one or two ſtalks, which riſe about nine inches high, the lower part being garniſhed with oval leaves by pairs on each foot-ſtalk; but the upper part of the ſtalk where the flowers come out, is garniſhed with ſmall leaves, ending in acute points, ſitting cloſe to the ſtalks, and at each of theſe is ſituated a ſingle, ſmall, yellow flower, incloſed by the two leaves. Theſe make but little appearance, and are ſucceeded by oblong pods, containing one kidney-ſhaped ſeed.

The ſixth ſort was ſent me by the the late Dr. Houſtoun from La Vera Cruz, where he found it growing naturally, as it alſo does in Jamaica. This is an annual plant, which riſes with a ſhrubby ſtalk upward of four feet high, dividing into ſeveral branches, which are garniſhed with oblong oval leaves that are trifoliate, ſtanding upon pretty long foot-ſtalks, the middle lobe ſtanding an inch beyond the other two; the branches are terminated by long looſe panicles of purple flowers, which are ſucceeded by narrow jointed pods which are twiſted. Theſe plants flower in July, and their ſeeds ripen in autumn.

The two laſt mentioned are tender plants, ſo their ſeeds muſt be ſown in the ſpring upon a hot-bed; and when the plants are fit to remove, they ſhould be each planted in a ſeparate ſmall pot, filled with light earth, and plunged into a hot-bed, keeping them ſhaded from the ſun till they have taken new root;

then they muſt be treated in the ſame way as other tender plants from hot countries, always keeping them in the ſtove or glaſs-caſe, otherwiſe they will not flower or produce ſeeds in England.

The ſeventh ſort grows naturally in Jamaica, from whence the ſeeds were ſent me by the late Dr. Houſtoun. This is a ſhrubby plant, which riſes about five feet high, and divides into ſeveral branches, which are garniſhed with trifoliate leaves which are oval, the middle lobe being much larger than the other two; the ſtalks are terminated by long ſpikes of ſmall purple flowers, which are ſucceeded by narrow pods, ſtrait on one ſide, but jointed on the other.

The eighth ſort was ſent me from La Vera Cruz by the late Dr. Houſtoun, who found it growing there naturally. This riſes with a ſhrubby ſtalk ſix or ſeven feet high, dividing into ſeveral branches, which are garniſhed with trifoliate oval leaves, ſilky and white on their under ſide, but of a pale green on their upper ſide; the flowers come out in long narrow ſpikes from the wings, and at the end of the branches, ſitting cloſe to the ſtalks; they are ſmall, of a bright purple colour, and are ſucceeded by flat, ſmooth, jointed pods, about one inch long, each joint having one kidney-ſhaped ſeed.

The two laſt ſorts will continue two or three years, if the plants are placed in the bark-ſtove. They are propagated by ſeeds, which muſt be ſown upon a hot-bed, and the plants treated in the ſame manner as thoſe juſt before-mentioned; and when they have obtained height, they ſhould be removed into the bark-ſtove, where they ſhould conſtantly remain, allowing them a large ſhare of air in warm weather. Theſe plants ſeldom flower till the ſecond year, when they will produce ſeeds which ripen in the autumn.

The ninth ſort is an annual plant, which grows naturally at La Vera Cruz, from whence it was ſent me by the late Dr. Houſtoun. This ſeldom riſes more than eight or nine inches high, ſending out ſeveral branches from the root, which are diffuſed and hairy; they are cloſely garniſhed with ſmall, oval, trifoliate leaves, a little hoary. The flowers grow in cloſe ſhort ſpikes; they are purple, and have very hairy empalements.

The tenth ſort grows naturally in Jamaica. This hath ligneous trailing ſtalks a foot and a half long, ſending out ſeveral branches on each ſide, which are garniſhed with ſmall, round, trifoliate leaves, of a pale green colour; the flowers are produced in very looſe ſpikes at the ends of the branches; they are ſmall, and of a pale purpliſh colour, ſucceeded by narrow twiſted pods which are jointed, each joint being four cornered, containing a ſingle, ſmall, compreſſed ſeed.

The two laſt ſorts being annual, require the ſame treatment as the fifth and ſixth ſorts before-mentioned, with which management they will flower and ripen their ſeeds in this country.

The eleventh ſort is a ſhrubby plant, which riſes with triangular ſtalks five or ſix feet high, dividing into ſeveral branches, garniſhed with heart-ſhaped trifoliate leaves, ending in acute points; the flowers are produced in very long ſpikes at the end of the branches, which are of a pale purple colour, and are ſucceeded by narrow jointed pods which are variouſly twiſted; the ſeeds are ſmall and compreſſed.

This plant grows naturally in Jamaica, from whence the ſeeds were ſent me by the late Dr. Houſtoun. It will continue three or four years, if the plants are treated in the ſame manner directed for the ſeventh and eighth ſorts, and will perfect ſeeds in this country.

The twelfth ſort is annual, the ſeeds of it were ſent me by the late Dr. Houſtoun from Campeachy. This hath a paniculated ſtalk, which riſes about two feet high, garniſhed with heart-ſhaped trifoliate leaves; the upper part of the ſtalk branches out into panicles of flowers, which are of a pale purple colour; theſe are ſucceeded by lunulated compreſſed pods, which ſtand oblique to the ſtalk, each containing one compreſſed kidney-ſhaped ſeed. This ſort is propagated by ſeeds, and requires the ſame treatment as the fifth and ſixth ſorts.

The thirteenth ſort was ſent me from La Vera Cruz, by the late Dr. Houſtoun. This hath a twining ſtalk, which gets round the trees and ſhrubs which grow near it, and climbs to the height of ten or twelve feet, garniſhed with obverſe, oval, trifoliate leaves, ſtanding upon pretty long foot-ſtalks; the flowers are produced in very long ſpikes, which are reflexed; they are of a dark purple colour, and ſit cloſe to the ſtalk. This is an abiding plant, which requires a ſtove to preſerve it in this country, ſo the plants ſhould be treated in the ſame manner as the ſeventh and eighth ſorts.

The fourteenth ſort is an annual plant, which grows naturally in both Indies. The ſeeds of this were ſent me from the Havannah by the late Dr. Houſtoun; it hath trailing branches near a foot long, which are garniſhed with round trifoliate leaves, a little indented at the top, very like in ſhape to thoſe of the Strawberry Trefoil; the ſtalks and under ſide of the leaves are hairy; the flowers are produced toward the end of the branches, ſometimes ſingle, and at other times two at a joint; they are of a purple colour and ſmall; theſe are ſucceeded by pods about an inch long, which are ſtrait on one ſide, and jointed on the other. This flowers the end of July, and ſometimes perfects ſeeds here.

The fifteenth ſort is a low annual plant, having ſlender ſtalks near a foot long, their lower part being garniſhed with ſingle oval leaves, ſtanding upon ſlender foot-ſtalks; their upper part is adorned with flowers, which come out by pairs above each other, to the end of the ſtalk; they are but ſmall, and of a reddiſh yellow colour; theſe are ſucceeded by jointed narrow pods, which ſit cloſe to the ſtalk, and are ſickle-ſhaped. The two laſt mentioned are annual plants, which require the ſame culture as the fifth and ſixth ſorts.

The ſixteenth ſort was ſent me by the late Dr. Dale, from South Carolina. This hath a perennial root, from which ariſe two or three ſhrubby hairy ſtalks near two feet high, branching out on every ſide near the top, garniſhed with oval, ſpear-ſhaped, trifoliate leaves, which are hairy on their under ſide, and ſtand upon ſhort foot-ſtalks; the flowers are produced at the end of the branches in ſhort ſpikes; they are of a purpliſh yellow colour, and ſmall; the ſtalks of this ſort decay every autumn, and new ones ariſe in the ſpring. It is propagated by ſeeds, which ſhould be ſown upon a hot-bed in the ſpring, and when the plants are fit to remove, they ſhould be planted in ſeparate ſmall pots filled with light earth, and plunged into a moderate hot-bed, obſerving to ſhade them until they have taken new root; then they ſhould have a large ſhare of air admitted to them in warm weather, and in ſummer they may be expoſed to the open air, but in the autumn they muſt be placed under a frame to ſcreen them from froſt; the following ſpring ſome of theſe plants muſt be ſhaken out of the pots and planted in a warm border, where, if the ſummer proves warm, they will flower, but theſe ſeldom perfect their ſeeds; therefore two or three plants ſhould be put into larger pots, and plunged into a moderate hot-bed, which will bring them early into flower; ſo that if the glaſſes are kept over them in bad weather, theſe will ripen their ſeeds in autumn, and the roots will continue ſome years, if they are ſcreened from froſt in winter.

The ſeventeenth ſort was ſent me with the laſt, by the ſame gentleman, from South Carolina. This hath a perennial root and an annual ſtalk, which grows erect about two feet high, garniſhed with long trifoliate leaves, which are rounded at their baſe where they are broadeſt, and narrowed all the way to a point; they are near three inches and a half long, and half an inch broad at their baſe, of a light green colour, and ſmooth; the two ſide lobes ſit pretty cloſe to the ſtalk, but the middle one ſits upon a foot-ſtalk an inch long; the flowers are produced in long ſpikes from the wings of the ſtalk, growing erect; the lower part of the ſpike is but thinly ſet with flowers, but on the upper part they are diſpoſed very cloſe; theſe are ſmall, and of a bright yellow colour, ſitting very cloſe to the ſtalks, and are ſucceeded by jointed pods ſtrait on one ſide.

This plant is propagated by ſeeds, and requires the ſame treatment as the laſt mentioned, with which it will flower and produce ripe ſeeds.

The eighteenth ſort grows naturally in Syria, where it is one of the beauties of the country. It riſes with ſhrubby ſtalks about three feet high, which branch out on every ſide, and are garniſhed with ſingle leaves, ſhaped like thoſe of the broad-leaved Knot-graſs; they are very ſmooth, of a pale green colour, and ſtand on ſhort foot-ſtalks; under theſe leaves come out thorns, which are near an inch long, of a reddiſh brown colour; the flowers come out from the ſide of the branches in ſmall cluſters; they are of a purple colour in the middle, and reddiſh about the rims; theſe are ſucceeded by pods, which are ſtrait on one ſide, and jointed on the other, bending a little in ſhape of a ſickle. This plant is at preſent pretty rare in the Engliſh gardens; it is propagated by ſeeds, which will frequently lie a year in the ground before they vegetate, therefore ſhould be ſown in pots filled with light earth, and plunged into a moderate hot-bed; and if the plants do not appear by the beginning of June, the pots ſhould be taken out of the bed, and placed where they may have only the morning ſun, keeping them clean from weeds; and in the autumn, they ſhould be plunged into an old bed of tanners bark under a frame, where they may be ſcreened from the froſt and hard rains in the winter, and in ſpring plunged into a freſh hot-bed, which will bring up the plants: when theſe are fit to remove, they ſhould be each planted into a ſeparate ſmall pot, filled with light earth, and plunged into a very moderate hot-bed, ſhading them from the ſun till they have taken new root; then they ſhould be gradually hardened to bear the open air, into which they ſhould be removed in June, placing them in a ſheltered ſituation, where they may remain till the autumn; when, if they are plunged into an old tan-bed under a frame, where, in mild weather they may enjoy the free air, and be protected from froſt, they will ſucceed better than if placed in a greenhouſe, or more tenderly treated. I have ſeen this plant growing in the full ground, in a very warm border, where, by covering it in froſty weather, it had endured two winters, but a ſevere froſt happening the third winter entirely killed it.

From this ſhrub the Perſian Manna is collected, which is an exſudation of the nutritious juice of the plant. This drug is chiefly gathered about Tauris, a town in Perſia, where the ſhrub grows plentifully. Sir George Wheeler found it growing in Tinos, and ſuppoſed it was an undeſcribed plant. Tournefort found it in plenty in many of the plains in Armenia and Georgia, and made a particular genus of it under the title of Alhagi.

The nineteenth ſort grows naturally in India, from whence the ſeeds have been lately brought to Europe, and ſeveral plants have been raiſed in the Engliſh gardens; theſe have leaves ſo like thoſe of the Orange-tree, as ſcarcely to be diſtinguiſhed while young; but as there are not any plants here of a large ſize, ſo I can give no further account of this ſort at preſent.

The twentieth ſort was ſent me from Carthagena in New Spain, by the late Dr. Houſtoun: this is a perennial plant with a twining ſtalk, which twiſts round any neighbouring ſupport, riſing to the height of ten or twelve feet, ſending out a few ſmall branches from the ſide, garniſhed with oval leaves four or five inches long, and an inch and a half broad in the middle; the under ſide of the leaves are like ſattin; the flowers are white, coming out from the ſide of the ſtalk in cloſe bunches; they are of the ſame form with the other ſpecies of this genus, and are ſucceeded by ſhort pods, containing one or two kidney-ſhaped ſeeds.

The ſeeds of the twenty-firſt ſort I received from the Eaſt-Indies; this is an annual plant, which riſes about three feet high, having a ſlender ſtalk inclining to be ſhrubby, garniſhed with oval leaves placed ſingle on very ſhort foot-ſtalks; ſome of the plants ſend out one or two ſlender branches from the main ſtalk, the lower part of which are garniſhed with leaves of the ſame form with thoſe on the principal ſtalk, but are ſmaller: the upper part of the principal ſtalk and the branches are garniſhed with flowers near a foot in length, which are of a worn-out purple colour, ſtanding ſingle at each joint: theſe are ſucceeded by jointed pods an inch and a half long, containing three or four kidney-ſhaped ſeeds in each.

Theſe two ſorts are too tender to thrive in the open air in England; they are both propagated by ſeeds, which muſt be ſown on a hot-bed early in the ſpring; and when the plants are come up, and fit to remove, they ſhould be parted, and each planted in a ſeparate ſmall pot, plunging them into a freſh hot-bed, where they ſhould be ſcreened from the ſun till they have taken new root; after which, they ſhould be treated in the ſame manner as other tender plants. The twenty-firſt ſort muſt be placed in the bark-ſtove in autumn, but the other will ripen ſeeds the ſame year the beginning of October.

HEDYSARUM Zeylanicum majus & minus. See ÆSCHYNOMENE.

HEDYSARUM mimoſæ foliis. See ÆSCHYNOMENE.

HELENIUM. Lin. Gen. Plant. 863. Heleniaſtrum. Vaill. Act. R. Par. 1720. Baſtard Sun-flower.

The Characters are,

It hath a flower compoſed of ſeveral hermaphrodite florets, which form the diſk, and female half florets which compoſe the rays. The hermaphrodite florets are tubulous, and cut into five parts at the brim; theſe have each five ſhort hairy ſtamina, terminated by cylindrical ſummits, with an oblong germen ſupporting a ſlender ſtyle, crowned by a bifid ſtigma. The germen afterward becomes an angular ſingle ſeed, crowned by a ſmall five-pointed empalement. The female florets in the border have ſhort tubes, and are ſtretched out on one ſide like a tongue to form the ray; theſe are cut into five ſegments at their points, where they are broad. The female flowers have no ſtamina, but have an oblong germen, which turns to a ſingle ſeed like thoſe of the hermaphrodite flowers; theſe are all included in one common ſingle empalement, which ſpreads open, and is cut into ſeveral ſegments.

This genus of plants is ranged in the ſecond ſection of Linnæus's nineteenth claſs, which includes thoſe plants which have compound flowers, the hermaphrodite florets in the center, and the female half florets on the border, being both fruitful.

The Species are,

1. Helenium (*Autumnale*) foliis lanceolatis-linearibus integerrimis glabris, pedunculis nudis unifloris. *Helenium with ſpear-ſhaped narrow leaves, which are ſmooth, entire, and naked foot-ſtalks with ſingle flowers.* Heleniaſtrum folio longiore & anguſtiore. Vaill. Act. R. Par. 1720. *Baſtard Sun-flower with a longer and narrower leaf.*
2. Helenium (*Latifolium*) foliis lanceolatis acutis ſerratis, pedunculis brevioribus, calycibus multifidis. *Helenium with pointed, ſpear-ſhaped, ſawed leaves, ſhorter foot-ſtalks, and a many-pointed empalement.* Heleniaſtrum folio breviore & latiore. Vaill. Act. R. S. 1720. *Baſtard Sun-flower with a broader and ſhorter leaf.*

Theſe plants riſe to the height of ſix or ſeven feet in good ground; the roots, when large, ſend up a great number of ſtalks, which branch toward the top; thoſe of the firſt ſort are garniſhed with ſmooth leaves, which are three inches and a half long, and half an inch broad in the middle, with entire edges ſitting cloſe to the ſtalks, and from their baſe is extended a leafy border along the ſtalk, ſo as to form what was generally termed a winged ſtalk, but Linnæus calls it a running leaf; the upper part of the ſtalk divides, and from each diviſion ariſes a naked foot-ſtalk about three inches long, ſuſtaining one yellow flower at the top, ſhaped like a Sun-flower, but much ſmaller, having long rays, which are jagged pretty deep into four or five ſegments; theſe appear in Auguſt, and there is a ſucceſſion of flowers on the plants till the froſt puts a ſtop to them.

The ſecond ſort hath the appearance of the firſt, but the leaves are not three inches long, and are more than an inch broad in the middle, ending in acute points, and are ſharply ſawed on their edges. The flowers ſtand upon ſhorter foot-ſtalks, growing cloſer together, for the ſtalks of this do not branch near ſo much as thoſe of the other; they both flower at the ſame ſeaſon.

There is alſo another ſort with leaves as narrow as the firſt, which are acutely indented on the edges. The ſtalks branch at the top ſomewhat like thoſe of the firſt, but the middle flowers have much ſhorter foot-ſtalks than thoſe which branch on the ſide, and are garniſhed with ſmall leaves, almoſt to the top; but I am not certain if this is a diſtinct ſpecies, or only a variety which has accidentally riſen from the ſeeds of the other.

Theſe plants are both of them natives of America; the ſeeds of both ſorts I have received from Virginia and New England, where they grow wild in great plenty in the woods, and other ſhady places where the ground is moiſt. They may be propagated by ſeeds, or by parting their roots; but the latter is generally practiſed in this country, becauſe they ſeldom perfect their ſeeds here; but if the ſeeds are procured from abroad, they ſhould be ſown the beginning of March on a border of light earth; and if the ſeeds ſhould not come up the firſt year, the ground ſhould not be diſturbed, becauſe they often remain a whole year in the ground before the plants come up; in which caſe there is nothing more to be done, but to keep the ground clear from weeds, and wait until the plants riſe. When they appear, if the ſeaſon proves dry, they muſt be often watered, which will greatly forward their growth; and where the plants come up too cloſe to each other, they ſhould be thinned, and tranſplanted out into beds a foot aſunder every way, being careful to ſhade them until they have taken root, as alſo to water them in dry weather. In autumn they may be tranſplanted where they are to remain, and the following ſummer they will produce their flowers, which will continue till the froſt prevents them; and their roots will abide many years, and afford many offsets, by which they may be increaſed.

The beſt ſeaſon to tranſplant the old roots, and to part them for increaſe, is in the end of October, when their flowers are paſt, or the beginning of March, juſt before they begin to ſhoot; but if the ſpring ſhould prove dry, they muſt be duly watered, otherwiſe they will not produce many flowers the ſame year; theſe plants ſhould not be removed oftener than every other year, if they are expected to flower ſtrong; they delight in a ſoil rather moiſt than dry, provided it be not too ſtrong, or holds the wet in winter; but if they are planted in a dry ſoil, they muſt be often and plentifully watered in dry weather, to make them produce plenty of flowers.

HELENIUM, Elecampane. See Inula.

HELIANTHEMUM. Tourn. Inſt. R. H. 248. tab. 128. Ciſtus. Lin. Gen. Plant. 598. *Dwarf Ciſtus, or Sun-flower.*

The Characters are,

The flower has a three-leaved empalement, which is permanent, which afterward covers the ſeed-veſſel. It hath five roundiſh petals which ſpread open, with a great number of erect ſtamina, which are terminated by ſmall roundiſh ſummits. In the center is ſituated an oval germen, ſupporting a ſingle ſtyle the length of the ſtamina, crowned by an obtuſe ſtigma. The germen afterward becomes a roundiſh, or oval capſule, with three cells, opening in three parts, filled with ſmall roundiſh ſeeds.

This genus of plants is joined by Dr. Linnæus to that of Ciſtus, and is ranged in the firſt ſection of his thirteenth claſs, which includes thoſe plants whoſe flowers have many ſtamina and one ſtyle. As the empalement of the flower has but three leaves, and thoſe of Ciſtus five, and the capſule of the Helianthemum has but three cells, and that of Ciſtus five, ſo theſe characters are ſufficient to admit of their being ſeparated into different genera; and as there are a great number of ſpecies of both ſorts, ſo by this ſeparation they may be better aſcertained.

The Species are,

1. Helianthemum (*Chamæciſtus*) caulibus procumbentibus ſuffruticoſis, foliis oblongis ſubpiloſis, ſtipulis lanceolatis. *Dwarf Ciſtus with trailing ſhrubby ſtalks, oblong hairy leaves, and ſpear-ſhaped ſtipulæ.* Helianthemum vulgare flore luteo. J. B. 2. 15. *Common Dwarf Ciſtus with a yellow flower.*
2. Helianthemum (*Germanicum*) caulibus procumbentibus ſuffruticoſis, ramoſiſſimis, ſpicis florum longioribus. *Dwarf Ciſtus with trailing ſhrubby ſtalks full of branches, and longer ſpikes to the flowers.* Helianthemum album Germanicum. Tab. Icon. 1062. *White German Dwarf Ciſtus.*
3. Helianthemum (*Piloſus*) caulibus ſuffruticoſis piloſis foliis lanceolatis obtuſis, ſpicis reflexis. *Dwarf Ciſtus with hairy ſhrubby ſtalks, blunt ſpear-ſhaped leaves, and reflexed ſpikes of flowers.* Helianthemum foliis majoribus, flore albo. J. B. 2. 16. *Dwarf Ciſtus with larger leaves and a white flower.*
4. Helianthemum (*Apenninum*) incanum, caulibus ſuffruticoſis erectis, foliis lanceolatis hirſutis. *Hoary Dwarf Ciſtus with erect ſhrubby ſtalks, and hairy ſpear-ſhaped leaves.* Helianthemum ſaxatile, foliis & caulibus incanis, floribus albis, Appenini montis. Mentz. Pug. tab. 8. *Rock Dwarf Ciſtus of the Apennines, with hoary ſtalks and leaves, and white flowers.*
5. Helianthemum (*Umbellatum*) caule procumbente non ramoſo, foliis linearibus incanis oppoſitis. *Dwarf Ciſtus with an unbranched trailing ſtalk, and narrow hoary leaves placed oppoſite.* Helianthemum folio thymi incano. J. B. 2. 19. *Dwarf Ciſtus with a hairy Thyme leaf.*
6. Helianthemum (*Fumana*) caule ſuffruticoſo procumbente, foliis linearibus alternis, floribus auriculatis. *Dwarf Ciſtus with a ſhrubby trailing ſtalk, very narrow leaves placed alternate, and auriculated flowers.* Helianthemum tenuifolium glabrum luteo flore, per humum ſparſum. J. B. 2. 18. *Smooth narrow-leaved Dwarf Ciſtus, with a yellow flower and trailing ſtalks.*
7. Helianthemum (*Sampſuchifolium*) caule ſuffruticoſo procumbente, foliis lanceolatis oppoſitis, pedunculis longioribus, calycibus hirſutis. *Dwarf Ciſtus with a ſhrubby trailing ſtalk, ſpear-ſhaped leaves placed oppoſite, longer foot-ſtalks to the flowers, and hairy empalements.* Helianthemum ſive Ciſtus humilis, folio ſampſuchi, capitulis valde hirſutis. J. B. 2. 20. *Dwarf Ciſtus with a Marjoram leaf, and very hairy heads.*
8. Helianthemum (*Serpillifolium*) caule ſuffruticoſo procumbente, foliis linearibus oppoſitis, floribus umbellatis. *Dwarf Ciſtus with a ſhrubby trailing ſtalk, very narrow leaves placed oppoſite, and flowers growing in an umbel.* Helianthemum folio thymi floribus umbellatis. Tourn. Inſt. 250. *Dwarf Ciſtus with a Thyme leaf and umbellated flowers.*
9. Helianthemum (*Ciſtifolium*) caulibus procumbentibus ſuffruticoſis glabris, foliis ovato lanceolatis oppoſitis, pedunculis longioribus. *Dwarf Ciſtus with ſhrubby trailing ſtalks which are ſmooth, oval ſpear-ſhaped leaves placed oppoſite, and longer foot-ſtalks to the flowers.* Helianthemum Germanicum luteum Ciſti folio. Boerh. *Yellow German Dwarf Ciſtus with a Rock Roſe leaf.*
10. Helianthemum (*Tuberaria*) caule lignoſo perenne, foliis radicalibus ovatis trinerviis tomentoſis caulinis glabris lanceolatis alternis. *Perennial Dwarf Ciſtus with a woody ſtalk, whoſe lower leaves are oval, woolly, with three veins, thoſe on the ſtalks ſmooth, ſpear-ſhaped, and placed alternate.* Helianthemum plantaginis folio perenne. Tourn. Inſt. 250. *Perennial Dwarf Ciſtus with a Plantain leaf.*
11. Helianthemum (*Polifolium*) caulibus ſeſſilibus ſuffruticoſis, foliis lanceolatis oppoſitis tomentoſis caule florali racemoſo. *Dwarf Ciſtus with very ſhort ſhrubby ſtalks, woolly ſpear-ſhaped leaves placed oppoſite, and a*

branching flower-ſtalk. Helianthemum foliis polii montani. Tourn. Inſt. 249. *Dwarf Ciſtus with leaves like Poley Mountain.*

12. Helianthemum (*Nummularium*) caule ſuffruticoſo procumbente, foliis ovatis nervoſis, ſubtus incanis. *Dwarf Ciſtus with a ſhrubby trailing ſtalk, and oval veined leaves, white on their under ſide.* Helianthemum ad nummulariam accedens. J. B. 2. 20. *Dwarf Ciſtus reſembling Moneywort.*

13. Helianthemum (*Lavendulæfoliam*) caule ſuffruticoſo, foliis lineari-lanceolatis oppoſitis ſubtus tomentoſis. *Dwarf Ciſtus with a ſhrubby ſtalk, and narrow ſpear-ſhaped leaves placed oppoſite, which are woolly on their under ſide.* Helianthemum lavendulæ folio. Tourn. Inſt. 249. *Dwarf Ciſtus with a Lavender leaf.*

14. Helianthemum (*Hirtum*) caule ſuffruticoſo erecto, foliis linearibus margines revolutis ſubtus incanis. *Dwarf Ciſtus with a ſhrubby erect ſtalk, and narrow leaves reflexed on their edges, with their under ſide hoary.* Helianthemum foliis Roriſmarini ſplendentibus, ſubtus incanis. Tourn. Inſt. 250. *Dwarf Ciſtus with ſhining Roſemary leaves, which are hoary on their under ſide.*

15. Helianthemum (*Surrejanum*) caulibus ſuffruticoſis procumbentibus, foliis oblongo-ovatis ſubhirſutis, petalis acuminatis reflexis. *Dwarf Ciſtus with trailing ſhrubby ſtalks, oblong oval hairy leaves, and acute-pointed reflexed petals to the flowers.* Helianthemum vulgare petalis florum peranguſtis. Hort. Elth. 177. tab. 145. *Common Dwarf Ciſtus with narrow petals to the flowers.*

16. Helianthemum (*Luſitanicum*) caule ſuffruticoſo erecto, foliis lanceolatis incanis glabris caule florali ramoſo. *Dwarf Ciſtus with a ſhrubby upright ſtalk, hoary ſpear-ſhaped leaves, which are ſmooth, and branching flower-ſtalks.* Helianthemum Luſitanicum, mari folio incano, flore luteo. Tourn. Inſt. 250. *Portugal Dwarf Ciſtus with a hoary Marum leaf, and a yellow flower.*

17. Helianthemum (*Roſeum*) caule ſuffruticoſo, foliis oblongo-ovatis oppoſitis, ſummis linearibus alternis. *Dwarf Ciſtus with a ſhrubby ſtalk, oblong oval leaves placed oppoſite, thoſe toward the top being narrow and alternate.* Helianthemum ampliore folio, flore roſeo. Sherard. Act. Phil. N°. 383. *Dwarf Ciſtus with a larger leaf, and Roſe-coloured flower.*

18. Helianthemum (*Guttatum*) caule herbaceo hirſuto, foliis lanceolato-linearibus piloſis, pedunculis longioribus. *Dwarf Ciſtus with an herbaceous ſtalk which is hairy, narrow ſpear-ſhaped hairy leaves, and longer foot-ſtalks to the flowers.* Helianthemum flore maculoſo. Col. Cephr. 2. p. 78. *Dwarf Ciſtus with a ſpotted flower.*

19. Helianthemum (*Fugacium*) caule herbaceo, foliis ſubovatis piloſis, flore fugaci. *Dwarf Ciſtus with an herbaceous ſtalk, hairy oval leaves, and a fugacious flower.* Helianthemum annuum humile, foliis ſubovatis, flore fugaci. Allion. *Annual Dwarf Ciſtus with oval leaves, and a fugacious flower.*

20. Helianthemum (*Ledifolium*) caule herbaceo erecto, foliis lanceolatis oppoſitis, floribus ſolitariis, capſulis maximis. *Dwarf Ciſtus with an erect herbaceous ſtalk, ſpear-ſhaped leaves placed oppoſite, flowers growing ſingly, and very large capſules.* Helianthemum Ledi folio. Tourn. Inſt. 249. *Dwarf Ciſtus with a Ledon leaf.*

21. Helianthemum (*Salicifolium*) caule herbaceo ramoſo, foliis oblongo-ovatis oppoſitis, ſummis alternis, floribus ſolitariis. *Dwarf Ciſtus with a branching herbaceous ſtalk, oblong oval leaves placed oppoſite, thoſe toward the top growing alternate, and ſolitary flowers.* Helianthemum ſalicis folio. Tourn. Inſt. 249. *Dwarf Ciſtus with a Willow leaf.*

22. Helianthemum (*Faſciculatum*) foliis faſciculatis. Royen. *Dwarf Ciſtus with leaves growing in bunches.*

23. Helianthemum (*Ægyptiacum*) herbaceum erectum, foliis lineari-lanceolatis petiolatis, calycibus inflatis corolla majoribus. *Dwarf Ciſtus with erect herbaceous ſtalks, linear ſpear-ſhaped leaves, and ſwelling empalements larger than the petals.*

24. Helianthemum (*Mariſolium*) caule herbaceo procumbente, foliis ovatis tomentoſis ſeſſilibus. *Dwarf Ciſtus with an herbaceous trailing ſtalk, and oval woolly leaves ſitting cloſe to the branches.* Helianthemum Alpinum, folio piloſellæ minoris Fuchſii. J. B. 2. 18. *Hoary Dwarf Ciſtus of the Alps, with leſſer Cat's-foot leaves.*

The firſt ſort grows naturally on the chalky hills and banks in many parts of England; the ſtalks of this plant are ligneous and ſlender, trailing upon the ground, extending themſelves near a foot each way; theſe are garniſhed with ſmall oblong leaves, of a dark green on their upper ſide, but of a grayiſh colour on their under. The flowers are produced at the end of the ſtalks in looſe ſpikes; they are compoſed of five deep yellow petals, which ſpread open in the day, but ſhut cloſe in the evening; theſe appear in June and July, and are ſucceeded by roundiſh capſules, incloſing many angular ſeeds, which ripen in Auguſt and September, and the roots laſt ſeveral years.

The ſecond ſort grows naturally in Germany; the ſtalks of this are much larger, and extend farther than thoſe of the firſt; the leaves are longer, and are hoary; there are three accuminated ſtipula at each of the lower joints, which are erect. The ſpikes of flowers are much longer than thoſe of the former, and the flowers are white and larger. The empalement of the flowers are hairy and whitiſh; theſe differences are laſting from ſeeds.

The third ſort grows naturally in the ſouth of France, in Italy, and Germany. The ſtalks of this grow more erect than either of the former, and are more ligneous. The joints are farther aſunder; the leaves are longer and hairy; the ſpikes of flowers are generally reflexed; they are white, and the ſize of thoſe of the ſecond; the ſtipula of this are very narrow.

The fourth ſort grows naturally on the Apennine mountains; the ſtalks of this are more erect than thoſe of the third. The leaves are not ſo long, the ſtipula are very ſmall, and the whole plant is very hoary. The flowers are white, and the ſpikes are ſhorter and more compact than either of the former.

The fifth ſort grows naturally in the ſouth of France, in Spain, and Iſtria, from the laſt country I have received the ſeeds; this hath low trailing ſtalks, which are ligneous, but ſeldom branch, and are not more than four or five inches long. The leaves are narrow and hoary, and have no ſtipula at their baſe. The flowers are white, and are in ſmall cluſters at the end of the ſtalks; this ſort ſeldom continues longer than two years.

The ſixth ſort hath trailing ſhrubby ſtalks, which extend a foot in length, and are garniſhed with very narrow ſmooth leaves placed alternate; but thoſe ſhort ſtalks near the root, which do not flower, have ſhorter and finer leaves growing in cluſters; theſe have no ſtipula at their baſe. The flowers are placed thinly toward the end of the branches, they are yellow and auriculated; this ſort grows in the ſouth of France and Italy.

The ſeventh ſort hath very long, trailing, ligneous ſtalks, which are garniſhed with ſpear-ſhaped leaves placed oppoſite, which are very hairy, and gray on their under ſide, having at their baſe three long narrow ſtipula. The ſpikes of flowers are near a foot in length, but grow thinly; they are large, and of a deep yellow colour, with very hairy empalements; this grows naturally in the ſouth of France and Spain.

The eighth ſort hath very ſhrubby crooked ſtalks, covered with a purpliſh brown bark like the common heath. The branches are ſlender, and garniſhed with narrow ſtiff leaves like thoſe of Thyme, which ſtand oppoſite, having no ſtipula at their baſe. The flowers are produced on naked foot-ſtalks, which terminate the branches in a ſort of umbel; they are of a pale yellow colour, and a little ſmaller than thoſe of the common ſort; this grows naturally on the ſands near Fontainbleau, in France.

The ninth ſort grows naturally in Germany, from whence the ſeeds were ſent to the late Dr. Boerhaave, in whoſe curious garden near Leyden I gathered the ſeeds; this ſends out from a ligneous root a great number of trailing ſtalks, which are ſmooth, and extend more than a foot each way, garniſhed with oval, ſpear-ſhaped, ſmooth leaves, placed oppoſite, having at their baſe three ſpear-ſhaped ſtipula. The flowers are large, yellow, and grow in ſhort cluſters at the end of the branches; this always continues the ſame from ſeeds.

The tenth ſort grows naturally in Spain, from whence I received it; this hath a ſhort, thick, woody ſtalk, from which come out ſeveral ſhort ſide-branches, which are garniſhed with oval woolly leaves, having three longitudinal veins. The flower-ſtalk which ariſes from the main ſtem grows about nine inches high, having two or three narrow leaves placed alternate. The flowers are produced in pretty long pedicles toward the top of the ſtalk, and have very ſmooth empalements.

The eleventh ſort was ſent me from Verona, where it grows naturally; this hath a low ſhrubby ſtalk, from which come out a few ſhort branches, garniſhed with ſmall woolly ſpear-ſhaped leaves, placed oppoſite. The flower-ſtalk riſes about ſix inches high, and branches toward the top, where the flowers are produced on pretty long foot-ſtalks; they are white, and ſmaller than thoſe of the common ſort.

The twelfth ſort hath long ſhrubby ſtalks which trail on the ground, and divide into many branches, which are garniſhed with oval veined leaves of a light green on their upper ſide, but of a grayiſh colour below, with three narrow erect ſtipula at their baſe. The flowers are pretty large, white, and grow in cluſters at the end of the branches.

The thirteenth ſort hath ſhrubby ſtalks which grow pretty upright, garniſhed with narrow ſpear-ſhaped leaves, placed oppoſite, woolly on their under ſide, with three very narrow ſtipula growing at their baſe. The flowers are white, growing in long ſpikes at the end of the branches; this grows naturally in the ſouth of France.

The fourteenth ſort hath an erect ſhrubby ſtalk, which ſends out many ſide branches, whoſe joints are pretty cloſe, and are garniſhed with very narrow leaves, placed oppoſite, whoſe borders are reflexed; their upper ſide is of a lucid green, and their under ſide hoary. The flowers are pretty large, white, and grow in ſmall cluſters at the end of the branches; this grows naturally in Spain, from whence the roots were ſent me.

The fifteenth ſort was found by Mr. Edmund Du Bois, near Croydon, in Surry, and was at firſt ſuppoſed to be only an accidental variety of the common ſort, but the ſeeds of this always produce the ſame. I have cultivated this above thirty years, and never have found it vary from ſeeds; this is very like the common ſort, but the leaves are hairy. The petals of the flowers are ſtar-pointed, and ſmaller than thoſe of the common ſort.

The ſixteenth ſort hath upright ſhrubby ſtalks, which riſe a foot and a half high, ſending out branches the whole length; theſe are garniſhed with ſmall ſpear-ſhaped ſilvery leaves, placed oppoſite, which are ſmooth. The flower-ſtalks branch, and the flowers, which are white, are produced in ſhort ſpikes at the end of the branches.

The ſeventeenth ſort was found growing naturally by the late Dr. William Sherrard, near Smyrna, who ſent the ſeeds to England; this hath ſhrubby ſtalks which do not trail on the ground, garniſhed with oblong oval leaves placed oppoſite, but thoſe toward the top are narrow and placed alternate. The flowers are produced at the end of the branches in long looſe ſpikes; they are of a Roſe colour, and the ſize of thoſe of the common ſort.

The eighteenth ſort is annual; this grows naturally in France, Spain, Italy, and in Jerſey, where the late Dr. William Sherrard found it, and ſent the ſeeds to England; this hath a branching herbaceous ſtalk, which riſes four or five inches high, garniſhed with narrow ſpear-ſhaped leaves, placed oppoſite, which are covered with hairs; thoſe on the upper part of the ſtalks are placed alternate, and are narrower. The flowers are produced in looſe ſpikes at the end of the branches, ſtanding upon long foot-ſtalks; they are ſmall, and compoſed of five yellow petals, with a dark purple ſpot at the baſe of each; theſe flowers are very fugacious, for they open early in the morning, and their petals drop off in a few hours after, ſo that by ten of the clock the flowers are all fallen.

The nineteenth ſort grows naturally upon Mount Baldus, from whence the ſeeds were ſent me; this is an annual plant, which ſends out many herbaceous ſtalks from the root, garniſhed with oval leaves, which are hairy. The flowers are produced in looſe ſpikes at the end of the branches; they are of a pale yellow colour, and very fugacious, ſeldom laſting two hours before the petals fall off: there is another variety of this which grows about Verona, with upright ſtalks.

The twentieth ſort grows naturally in the ſouth of France and Italy, and was found by the late Dr. William Sherrard, growing near Smyrna, who ſent the ſeeds to England and Holland by a new title, ſuppoſing it to be a different plant; but when it was cultivated here, it proved to be the ſame with that growing in the ſouth of France; for this plant puts on different appearances, according to the ſoil and ſituation where it grows; for, in a good ſoil, where the plants ſtand ſingle, and are not injured by weeds, they will riſe near a foot and a half high, the leaves will be two inches and a half long, and near half an inch broad in the middle; but in a poor ſoil, or where the plants ſtand too cloſe, or are injured by weeds or neighbouring plants, they do not riſe more than half that height. The leaves are much narrower, and the ſeed-veſſels not half ſo large; ſo that any perſon finding theſe plants in two different ſituations may be deceived, and take them for different ſpecies; but when they are cultivated in a garden in the ſame ſoil and ſituation, they do not differ in any particular. This is an annual plant, which periſhes ſoon after the ſeeds are ripe.

The twenty-firſt ſort is an annual plant, which grows naturally in Spain and Portugal; this hath branching ſtalks, which riſe a foot high, garniſhed with oval oblong leaves placed oppoſite on the lower part of the ſtalk; but on the upper part they are alternate and narrow, a ſingle leaf being placed between each flower, which occaſions the title of Solitary Flowers, for they grow in looſe ſpikes at the end of the branches, in the ſame manner as the other ſpecies.

The twenty-ſecond ſort was ſent me by Dr. Adrian Van Royen, who received the ſeeds from the Cape of Good Hope. This riſes with a ſhrubby ſtalk about nine inches high, garniſhed with very narrow fine leaves, growing in cluſters; the flowers come out from the ſide and at the end of the branches, ſtanding upon ſlender foot-ſtalks; they are of a pale Straw colour, and very fugacious, ſeldom continuing longer than two hours before the petals fall off. This ſeldom continues longer than two years.

The twenty-third ſort grows naturally in Egypt; this is an annual plant having ſhrubby erect ſtalks, garniſhed with narrow ſpear-ſhaped leaves, ſtanding on foot-ſtalks; the upper part of the ſtalks are adorned with white flowers, whoſe petals are not ſo large as the empalement, and being very fugacious they make but little appearance: it flowers in July, and the ſeeds ripen in September, ſoon after which the plants decay.

The twenty-fourth ſort grows naturally about Kendal in Weſtmoreland, and in ſome parts of Lancaſhire, upon rocky ſituations. This hath trailing herbaceous ſtalks, which ſeldom extend more than three or four inches, garniſhed with oval leaves, which are very woolly, and ſit cloſe to the branches; the flowers are produced at the upper part of the branches; they are white and ſmall, ſo make no great appearance.

Moſt of the perennial ſorts of Dwarf Ciſtus are hardy, ſo will thrive in the open air in England; they are propagated by ſeeds, which may be ſown in places where the plants are to remain, and will require no other care but to keep them clean from weeds, and thin them where they are too cloſe, always obſerving to leave thoſe ſorts at a farther diſtance, whoſe ſtalks trail on the ground, and grow to the greateſt length. Theſe plants will continue ſeveral years, eſpecially in a poor dry ſoil; but in rich ground or moiſt ſituations, they ſeldom laſt long: but as they ripen ſeeds in plenty, ſo they may be eaſily repaired. They all flower about the ſame time as the common ſort, and their ſeeds ripen in the autumn.

The annual ſorts may be propagated with as great facility; for if their ſeeds are ſown upon a bed of common earth in April, the plants will come up in May, and require no other culture, but to thin them where they are too cloſe, and keep them clear from weeds. Theſe will flower in July, and the ſeeds ripen in the autumn. The twenty-ſecond ſort will thrive in the full ground in the ſame manner as the other; but unleſs the ſummer proves favourable, the ſeeds will not ripen: the roots have ſtood through the winter when the ſeaſon has proved mild, without any ſhelter, and have flowered the following ſummer.

The twenty-fourth ſort requires a ſhady ſituation, otherwiſe it will not thrive here.

HELIANTHUS. Lin. Gen. Plant. 877. Corona ſolis. Tourn. Inſt. R. H. 489. tab. 279. [of Ἥλιος, the ſun, and Ἄνθος, a flower,] i. e. Sun-flower; in French, *Soliel.*

This genus of plants was titled Corona ſolis, by moſt of the botanic writers; but this being a compound name, Dr. Linnæus has altered it to this of Helianthus: it has alſo by ſome been titled Heliotropium, which name is now applied to another genus of plants, very different from this.

The Characters are,

It hath a compound radiated flower, the border or rays being compoſed of female half-florets, which are barren, and the diſk of hermaphrodite florets, which are fruitful: theſe are contained in one common ſcaly empalement, whoſe ſcales are broad at their baſe, pointed at their ends, and expand. The hermaphrodite florets are cylindrical, ſwelling at their baſe, cut at the brim into five acute ſegments, which ſpread open; theſe have five ſtamina which are curved at bottom, as long as the tube, and terminated by tubulous ſummits. The germen, which is ſituated at the bottom of the tube, ſupports a ſlender ſtyle the length of the tube, crowned by a reflexed ſtigma, divided in two parts; the germen afterward becomes an oblong, blunt, four-cornered ſeed. The female half florets, which compoſe the border, are ſtretched out on one ſide like a tongue, which is long and entire; theſe have a germen in the bottom, but no ſtyle or ſtamina, and are not fruitful.

This genus of plants is ranged in the third ſection of Linnæus's nineteenth claſs, in which he includes thoſe plants whoſe flowers are compoſed of hermaphrodite fruitful flowers in the center, and female barren flowers in the circumference.

The Species are,

1. Helianthus (*Annuus*) foliis omnibus cordatis trinervatis, floribus cernuis. Lin. Sp. 1276. *Sun-flower, whoſe leaves are all heart-ſhaped, with three veins and a nodding flower.* Corona ſolis. Tabern. Icon. 763. and the Helenium Indicum maximum. C. B. P. 276. *Greateſt Indian Sun-flower, commonly called annual Sun-flower.*
2. Helianthus (*Multifloris*) foliis inferioribus cordatis trinervatis, ſuperioribus ovatis. Lin. Sp. Plant. 1277. *Sun-flower whoſe under leaves are heart-ſhaped, with three veins, and the upper leaves oval.* Corona ſolis minor fœmina. Tabern. Icon. 764. *Leſſer female Sun-flower, commonly called perennial Sun-flower.*
3. Helianthus (*Tuberoſus*) foliis ovato-cordatis triplinerviis. Lin. Sp. Plant. 1277. *Sun-flower with oval heart-ſhaped leaves with three nerves.* Corona ſolis parvo flore tuberoſâ radice. Tourn. Inſt. 489. *Sun-flower with a ſmall flower and a tuberous root, commonly called Jeruſalem Artichoke*; in French, *Taupinambours.*
4. Helianthus. (*Strumoſis*) radice fuſſi formi. Hort. Cliff. 420. *Sun-flower with a ſpindle-ſhaped root.* Corona ſolis latifolia altiſſima. Tourn. Inſt. 489. *Talleſt broad-leaved Sun-flower.*
5. Helianthus (*Giganteus*) foliis alternis lanceolatis ſcabris, baſi ciliatis, caule ſtricto ſcabro. Lin. Sp. Plant. 1278. *Sun-flower with ſpear-ſhaped leaves, and a ſlender rough ſtalk.* Chryſanthemum Virginianum altiſſimum anguſtifolium puniceis caulibus. Mor. Hiſt. 3. p. 24. *Talleſt Virginia Chryſanthemum, with a narrow leaf and purple ſtalks.*
6. Helianthus (*Divaricatus*) foliis oppoſitis ſeſſilibus ovato oblongis trinerviis, paniculâ dichotomâ. Lin. Sp. Plant. 1279. *Sun-flower with oblong, oppoſite, oval leaves, having three veins ſitting cloſe to the ſtalk, and a forked panicle.* Chryſanthemum, Virginianum repens, foliis aſperis binatim ſeſſilibus acuminatis. Mor. Hiſt. 3. p. 22. *Creeping Virginia Chrſyanthemum, with rough-pointed leaves, ſitting cloſe by pairs.*
7. Helianthus (*Trachelifolius*) foliis lanceolatis oppoſitis, ſuperne ſcabris, inferne trinerviis, caule dichotomo ramoſo. *Sun-flower with ſpear-ſhaped leaves placed oppoſite, whoſe upper ſurface is rough, the under having three veins and a divided ſtalk.* Corona ſolis trachelii folio, radice repente. Tourn. Inſt. 490. *Sun-flower with a Throatwort leaf, and a creeping root.*
8. Helianthus (*Ramoſiſſimus*) caule ramoſiſſimo, foliis lanceolatis ſcabris, inferioribus oppoſitis, ſummis alternis petiolatis, calycibus folioſis. *Sun-flower with a very branching ſtalk, rough ſpear-ſhaped leaves placed oppoſite at bottom, but alternate toward the top, having foot-ſtalks, and leafy empalements.* Corona ſolis trachelii folio tenuiore, calyce floris foliato. Act. Phil. N° 412. *Sun-flower with a narrow Throatwort leaf, and a leafy flower-cup.*
9. Helianthus (*Atrorubens*) foliis ovatis crenatis trinerviis ſcabris, ſquamis calycinis erectis longitudine diſci Flor. Virg. 103. *Sun-flower with oval, rough, crenated leaves, having three nerves, the ſcales of the empalement being erect, and as long as the diſk of the flower.* Corona ſolis Caroliniana, parvis floribus, folio trinervi amplo aſpero, pediculo alato. Martyn. Cent. 1. 20. *Carolina Sun-flower with ſmall flowers, large rough leaves having three veins, and a winged foot-ſtalk.*
10. Helianthus (*Decapetalus*) caule inferne lævi, folis lanceolato-cordatis, radiis decapetalis. Lin. Sp. Plant. 905. *Sun-flower with a ſmooth ſtalk, heart ſpear-ſhaped leaves, ſmooth on their upper ſide, and ten petals in the rays.*

All theſe ſpecies of Sun-flowers are natives of America, from whence we are often ſupplied with new kinds; and it is very remarkable, that there is not a ſingle ſpecies of this genus that is European; ſo that before America was diſcovered, we were wholly unacquainted with theſe plants. But although they are not originally of our own growth, yet they are become ſo familiar to our climate, as to thrive and increaſe full as well as if they were in their native country, (ſome of the very late flowering kinds excepted, which require a longer ſummer than we generally enjoy, to bring them to perfection;) and many of them are now ſo plentiful in England, that perſons unacquainted with the hiſtory of theſe plants, would imagine them at leaſt to have been inhabitants of this iſland many hundred years; particularly the Jeruſalem Artichoke, which, though it doth not produce ſeeds in our climate, yet doth ſo multiply by its knobbed roots, that, when once well fixed in a garden, it is not eaſily to be rooted out.

The firſt ſort is annual, and ſo well known as to require no deſcription. There are ſingle and double flowers of two different colours, one of a deep yellow, and the other of a ſulphur colour; but theſe vary, ſo are not worthy to be mentioned as different. They are eaſily propagated by ſeeds, which ſhould be ſown in March, upon a bed of common earth; and when the plants come up, they muſt be thinned where they are too cloſe, and kept clean from weeds; when the plants are grown ſix inches high, they may be taken up with balls of earth to their roots, and planted into the large borders of the pleaſure-garden, obſerving to water them till they have taken new root; after which they will require no other care, but to keep them clear from weeds.

In July the great flowers upon the tops of the ſtems will appear, amongſt which, the beſt and moſt double flowers of each kind ſhould be preſerved for ſeeds; for thoſe which flower later upon the ſide branches are neither ſo fair, nor do they perfect their ſeeds ſo well, as thoſe which are firſt in flower: when the flowers are quite faded and the ſeeds are formed, you ſhould carefully guard the heads from the ſparrows, which will otherwiſe devour moſt of the good ſeeds; and about the beginning of October, when the ſeeds are ripe, you ſhould cut off the heads with a ſmall part of the ſtem, and hang them up in a dry airy place for about a month, by which time the ſeeds will be perfectly dry and hard; when you may eaſily rub them out, and put them into bags or papers, preſerving them from vermin until the ſeaſon for ſowing them.

The ſeeds of this ſort of Sun-flower are excellent food for domeſtic poultry; therefore where a quantity of it can be ſaved, it will be of great uſe, where there are quantities of theſe fowls.

The other perennial ſorts rarely produce ſeeds in England, but moſt of them increaſe very faſt at their roots, eſpecially the creeping rooted kinds, which ſpread too far for ſmall gardens. The ſecond ſort, which is the moſt common in the Engliſh gardens, is the largeſt and moſt valuable flower, and is a very proper furniture for large borders in great gardens, as alſo for boſquets of large growing plants, or to intermix in ſmall quarters with ſhrubs, or in walks under trees, where few other plants will thrive; it is alſo a great ornament to gardens within the city, where it grows in defiance of the ſmoke, better than moſt other plants; and for its long continuance in flower, deſerves a place in moſt gardens, for the ſake of its flowers for baſons, &c. to adorn halls and chimneys, in a ſeaſon when we are at a loſs for other flowers. It begins flowering in July, and continues until October; there is a variety of this with very double flowers, which is now become ſo common in the Engliſh gardens, as to have almoſt baniſhed the ſingle ſort from hence.

The third, fourth, fifth, ſixth, and ſeventh ſorts may alſo have a place in ſome large borders of the garden, for the variety of their flowers; which, though not ſo fair as thoſe of the common ſort, yet will add to the diverſity; and as many of them are late flowerers, ſo we may continue the ſucceſſion of flowers longer in the ſeaſon.

Theſe ſorts are all of them very hardy, and will grow in almoſt any ſoil or ſituation; they are propagated by parting their roots into ſmall heads, which in one year's time will ſpread and increaſe greatly. The beſt ſeaſon for this work is in the middle of October, ſoon after the flowers are paſt, or very early in the ſpring, that they may be well rooted before the droughts come on; otherwiſe their flowers will be few in number, and not near ſo fair, and by this means their roots will be weak; but if they are planted in October, you will ſave the trouble of watering them; their roots being ſurely fixed before the dry weather, they will need no other trouble than to clear them from weeds.

The Jeruſalem Artichoke is propagated in many gardens for the roots, which are by ſome people as much eſteemed as Potatoes; but they are more watery and flaſhy, and are very ſubject to trouble the belly by their windy quality, which hath brought them almoſt into diſuſe.

Theſe are propagated by planting the ſmaller roots, or the larger ones cut in pieces, obſerving to preſerve a bud to each ſeparate piece, either in the ſpring or autumn, allowing them a good diſtance, for their roots will greatly multiply; the autumn following, when their ſtems decay, the roots may be taken up for uſe. Theſe ſhould be planted in ſome remote corner of the garden, for they are very unſightly while growing, and their roots are apt to over-run whatever grows near them, nor can they be eaſily deſtroyed when they are once well fixed in a garden.

The other ſpecies which have been ranged under this genus by Tournefort and others, are now removed to the following genera, under which titles they may be found.

Rudbeckia.
Silphium.

HELICTERES. Lin. Gen. Plant. 913. Iſora. Plum. Nov. Gen. 34. tab. 37. Screw-tree.

The Characters are,

The flower has a coriaceous empalement of one leaf, which is narrow at bottom, but ſpreads open at the top, where it is indented in five parts. The flower hath five oblong equal petals, which are longer than the empalement to which they are fixed. It hath ten ſhort ſtamina at the baſe of the germen, terminated by oblong ſummits, and five nectariums ſurrounding the germen, which have the appearance of petals. The ſtyle is very long, ſlender, and ſupports the germen at the top, which is roundiſh, and crowned by an acute ſtigma. The germen afterward turns to a twiſted ſpiral fruit with one cell, incloſing many kidney-ſhaped ſeeds.

This genus of plants is ranged in the ſixth ſection of Linnæus's twentieth claſs, which includes thoſe plants whoſe flowers have ten ſtamina which are connected to the ſtyle.

The Species are,

1. Helicteres (*Iſora*) foliis cordato-ovatis ſerratis, ſubtus tomentoſis, fructu tereti contorto. *Helicteres with oval heart-ſhaped leaves which are ſawed, and woolly on their under ſide, and a taper twiſted fruit.* Iſora althææ foliis, fructu longiore & anguſtiore. Plum. Nov. Gen. 24. *Screw-tree with Marſhmallow leaves, and a longer narrower fruit.*
2. Helicteres (*Breviore*) foliis cordatis acuminatis ſerratis, ſubtus tomentoſis, fructu brevi contorto. *Helicteres with heart-ſhaped, pointed, ſawed leaves, woolly on their under ſide, and a ſhort twiſted fruit.* Iſora althææ foliis, fructu breviore & craſſiore. Plum. Nov. 34. *Screw-tree with a Marſhmallow leaf, and a ſhorter thicker fruit.*
3. Helicteres (*Arboreſcens*) caule arboreo villoſo, foliis cordatis crenatis nervoſis ſubtus tomentoſis fructu ovato contorto villoſiſſimo. *Helicteres with a tree-like hairy ſtalk, heart-ſhaped, nervous, crenated leaves, woolly on their under ſide, and an oval, twiſted, very hairy fruit.* Iſora althææ folio ampliſſimo, fructu craſiſſimo & villoſo. Edit. prior. *Screw-tree with a very large Marſhmallow leaf, and a very thick hairy fruit.*

The firſt ſort grows naturally in the Bahama Iſlands, from whence I received the ſeeds. This riſes with a ſhrubby ſtalk five or ſix feet high, ſending out ſeveral lateral branches, which are covered with a ſoft yellowiſh down, garniſhed with heart-ſhaped leaves four inches long, and two and a half broad, ſawed on their edges, woolly on their under ſide, ſtanding on long foot-ſtalks; at the upper part of the branches the flowers come out oppoſite to the leaves, upon ſlender foot-ſtalks which are jointed; theſe are compoſed of five oblong white petals, and in the center ariſes the ſtyle, which is curved, three inches long, upon the top of which is ſituated the germen, crowned by an acute ſtigma. The germen afterward turns to a taper fruit two inches and a half long, compoſed of five capſules, which are cloſely twiſted over each other like a ſcrew; theſe are hairy, and have each one cell, containing ſeveral kidney-ſhaped ſeeds.

The ſecond ſort grows naturally in Jamaica, from whence the late Dr. Houſtoun ſent me the ſeeds. This riſes with a ſhrubby ſtalk nine or ten feet high, ſending out many lateral branches, covered with a ſmooth brown bark, garniſhed with heart-ſhaped leaves, which end in acute points, ſawed on their edges, a little woolly on their under ſide; the flowers are produced on the ſide of the branches, on ſhorter foot-ſtalks than the former; they are compoſed of five petals, and the ſtyle in the center, which is ſtrait, upright, and not half ſo long as the other; the fruit is thicker, not an inch long, but twiſted in the ſame manner.

The third ſort riſes with a ſtrong woody ſtalk twelve or fourteen feet high, ſending out many ligneous branches, which are cloſely covered with hairy down, garniſhed with large heart-ſhaped leaves, which are crenated on their edges, having large veins running from the midrib to the ſides; they are of a light yellowiſh green, and woolly on their under ſide: the flowers are produced from the ſide of the branches, they are of a yellowiſh white colour, and larger than thoſe of the other ſorts. The ſtyle is near four inches long, curved like that of the firſt ſort; the fruit is oval, about one inch long, very thick at the bottom, and cloſely covered with hairy down. This ſort was ſent me by Mr. Robert Millar, from Carthagena.

Theſe plants are propagated by ſeeds, which muſt be ſown upon a hot-bed in the ſpring, and when the plants are come up ſtrong enough to remove, they ſhould be each planted in a ſeparate ſmall pot, filled with light earth, and plunged into a moderate hot-bed of tan, obſerving to ſhade them from the ſun till they have taken new root; then they ſhould be treated in the ſame way as other tender plants from hot countries, raiſing the glaſſes every day in proportion to the weather, that the plants may enjoy freſh air, which will ſtrengthen them, and prevent their drawing up weak. In the ſummer the plants may remain under the frames, if there is ſufficient height for them to grow; but in autumn they muſt be plunged into the tan-bed in the ſtove, where they ſhould always remain, being careful to ſhift them into larger pots when they require it, and not give them too much wet in the winter; but in ſummer they ſhould have a large ſhare of air in warm weather, and require to be often refreſhed with water: the ſecond year from the ſeeds theſe plants have often flowered in the Chelſea garden, and the ſeeds have ſome years ripened there, but the plants will live ſeveral years with proper management.

HELIOCARPOS. Lin. Gen. Plant. 533. Montia. Houſt. Gen. We have no title in Engliſh for this plant.

The CHARACTERS are,

The flower hath one petal which is tubulous at the bottom, and cut into five ſegments which expand. It hath an empalement of one leaf, which is cut into five parts ſpreading open. In the center is ſituated a roundiſh germen, ſupporting two erect ſtyles, crowned by acute ſtigmas which ſtand apart; theſe are attended by twelve ſtamina, which are of the ſame length with the ſtyles, terminated by narrow twin ſummits which are proſtrate. The germen afterward becomes an oval compreſſed capſule, about three lines long and two broad, with a tranſverſe partition dividing it in two cells, each containing a ſingle roundiſh ſeed ending in a point; the borders of the capſule are ſet with hairs, reſembling rays.

This genus of plants is ranged in the ſecond ſection of Linnæus's eleventh claſs, intitled Dodecandria Digynia, which includes the plants whoſe flowers have twelve ſtamina and two ſtyles.

We have but one SPECIES of this plant, viz.

HELIOCARPOS (*Americana.*) Hort. Cliff. 211. tab. 16. Montia arboreſcens mori folio fructu racemoſo. Houſt. MSS. *Tree Montia with a Mulberry leaf and branching fruit.*

This plant was diſcovered by the late Dr. Houſtoun, growing naturally about Old La Vera Cruz in New Spain, from whence he ſent the ſeeds to England, which ſucceeded in the Chelſea garden, where the plants have produced flowers, and ripened ſeeds ſeveral years. It riſes with a thick, ſoft, woody ſtalk, from fifteen to eighteen feet high, ſending out ſeveral lateral branches toward the top, garniſhed with heart-ſhaped leaves full of veins, ſawed on their edges, and ending in acute points; they have foot-ſtalks three inches long, which ſtand oblique to the leaves, and are placed alternate; the flowers are produced at the end of the ſhoots, in branching cluſters; they are of a yellowiſh green, and are ſucceeded by flat compreſſed ſeed-veſſels of an oval ſhape, whoſe borders are cloſely ſet with threads repreſenting rays, of a browniſh colour when ripe; theſe capſules are divided into two cells by an intermediate partition, in each of theſe is lodged a ſingle roundiſh ſeed ending in a point.

This plant is propagated by ſeeds, which muſt be ſown upon a hot-bed in the ſpring; and when the plants are fit to remove, they ſhould be each planted in a ſeparate ſmall pot filled with light kitchen-garden earth, andd plunged into a hot-bed, treating them in the ſame way as other tender plants, which will not bear the open air in this country at any ſeaſon of the year; and while the plants are young, they require to be plunged in the tan-bed, but after they have acquired ſtrength, they will thrive in the dry ſtove. In winter they ſhould have but little water, and muſt be kept warm; but in ſummer they ſhould have plenty of freſh air in mild weather, and muſt be frequently refreſhed with water. With this management the plants will flower the third year, and produce good ſeeds, but may be preſerved ſeveral years with proper care.

I have ſowed the ſeeds of this plant which had been kept ten years, and came up as well as if it had been ſaved the former year; though from the appearance of the ſeeds, it ſeems as unlike to grow after the firſt year as any which I know.

HELIOPHILA. Lin. Gen. 816.

The CHARACTERS are,

It hath a four-leaved empalement, whoſe boraers have membranes; the two outer have ſmall bladders at their baſe. The flower has four roundiſh plain petals, placed in form of a croſs, and two nectariums, which are recurved toward the bladders of the empalement. It hath ſix ſtamina, four of which are longer than the other, terminated by oblong erect ſummits; and a cylindrical germen ſupporting a ſhort ſtyle, crowned by an obtuſe ſtigma; the germen afterward becomes a taper pod, with two cells filled with ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's fifteenth claſs, intitled Tetradynamia Siliquoſa, the flower having four long and two ſhort ſtamina, and the ſeeds being included in long pods.

The SPECIES are,

1. HELIOPHILA (*Integrifolia*) foliis lanceolatis indiviſis. N. Burman. *Heliophila with ſpear-ſhaped undivided leaves.* Leucoium Africanum, cœruleo flore, latifolium. H. L. 364. *African Gilliflower with a broad leaf and a blue flower.*
2. HELIOPHILA (*Coronopi folia*) foliis linearibus pinnatifidis. Lin. Sp. Plant. 927. *Heliophila with linear wing-pointed leaves.* Leucoium Africanum, cœruleo flore, anguſto coronopi folio majus. H. L. 364. *African Gilliflower, with narrow Hartſhorn leaves and blue flowers.*

Theſe are both annual plants, which grow naturally at the Cape of Good Hope; the firſt riſes with an erect ſtalk about four or five inches high, ſending out two or three ſide branches, garniſhed with long, narrow, entire green leaves, and terminated by a looſe bunch of blue flowers without ſcent, which are ſucceeded by taper pods near three inches long, having a double row of flat ſeeds.

The ſecond ſort grows about the ſame height, but branches more; the leaves are cut into many wing-pointed diviſions, and the flowers are like thoſe of the other ſort.

The ſeeds of both ſorts may be ſown in the ſpring on a ſouth border, and when the plants come up, if they are thinned and kept clean from weeds, it is all the culture they require.

HELIOTROPIUM. Lin. Gen. Plant. 164. Tourn. Inſt. R. H. 138. tab. 57. [Ἡλιοτρόπιον, of Ἥλιος, the ſun, and τρέπω, to turn.] Turnſole.

The CHARACTERS are,

The empalement of the flower is of one leaf, tubulous at bottom, but cut into five ſegments at the brim. The flower hath one petal, with a tube the length of the empalement, ſpreading flat above, where it is cut into five ſegments, which are alternately larger than the other; the chaps of the tube is cloſed, and hath five prominent ſcales, joined in form of a ſtar. It hath five ſhort ſtamina within the tube, terminated by ſmall ſummits, and four germen at the bottom of the tube, with one ſlender ſtyle the length of the ſtamina, crowned by an indented ſtigma. The germen afterward becomes ſo many ſeeds, ſitting in the empalement. This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, which includes thoſe plants whoſe flowers have five ſtamina and one ſtyle.

The SPECIES are,

1. HELIOTROPIUM (*Europæum*) foliis ovatis integerrimis tomentoſis rugoſis ſpicis conjugatis. Hort. Upſal. 33. *Heliotrope with oval, entire, woolly, rough leaves, and conjugated ſpikes.* Heliotropium majus Dioſcoridis. C. B. P. 253. The greater Turnſole of Dioſcorides.

2. HELIOTRIPIUM (*Indicum*) foliis cordato-ovatis acutis ſcabriuſculis, ſpicis ſolitariis, fructibus bifidis. Flor. Zeyl. 70. *Heliotrope with heart-ſhaped oval leaves, which are pointed and rough, ſingle ſpikes of flowers and bifid ſeeds.* Heliotropium Americanum cœruleum, foliis hormini. Acad. Reg. Sc. *Blue American Turnſole with Clary leaves.*

3. HELIOTROPIUM (*Horminifolium*) foliis lanceolato-ovatis acuminatis rugoſis, ſpicis ſolitariis gracilioribus alaribus & terminalibus. *Heliotrope with ſpear-ſhaped oval leaves, which are rough, and end in acute points, having ſlender ſingle ſpikes of flowers proceeding from the ſides and tops of the ſtalks.* Heliotropium Americanum cœruleum, foliis hormini anguſtioribus. H. L. *Blue American Turnſole with narrower Clary leaves.*

4. HELITROPIUM (*Capitatum*) foliis oblongo-ovatis integerrimis glabris ſubtus incanis, floribus capitatis alaribus, caule arboreſcente. *Heliotrope with oblong, oval, entire, ſmooth leaves, which are hoary on their under ſide, flowers growing in heads from the wings of the ſtalks, and a tree-like ſtalk.* Heliotropium arboreſcens, folio teucrii, flore albo in capitula denſa congeſto. Boerh. Ind. *Tree-like Turnſole, with a Germander leaf, and white flowers growing in thick ſhort heads.*

5. HELIOTROPIUM (*Canarienſe*) foliis ovatis crenatis oppoſitis, floribus capitatis alaribus dichotomis, caule arboreſcente. *Heliotrope with oval crenated leaves placed oppoſite, flowers growing in heads from the wings of the ſtalks, which diverge, and a tree-like ſtalk.* Heliotropium Canarienſe arboreſcens, folio ſcorodonæ. Hort. Amſt. *Canary tree-like Turnſole, with a Wood Sage leaf.*

6. HELIOTROPIUM (*Peruvianum*) foliis lanceolato-ovatis, caule fruticoſo, ſpicis numeroſis aggregato-corymboſis. Lin. Sp. 187. *Peruvian Helitrope with oval ſpear-ſhaped leaves, a ſhrubby ſtalk, and many ſpikes of flowers joined in a corymbus.*

7. HELIOTROPIUM (*Curaſſavicum*) foliis lanceolato-linearibus glabris aveniis, ſpicis conjugatis. Hort. Cliff. 45. *Heliotrope with narrow, ſpear-ſhaped, ſmooth leaves without veins, and conjugated ſpikes of flowers.* Heliotropium Curaſſavicum, foliis lini umbilicati. Par. Bat. Prod. *Heliotrope of Curaſſao, with a Venus Navelwort leaf.*

8. HELIOTROPIUM (*Gnaphalodes*) foliis linearibus obtuſis tomentoſis, pedunculis dichotomis, ſpicarum floribus quaternis, caule fruteſcente. Lin. Sp. 188. *Heliotrope with linear, obtuſe, woolly leaves, forked foot-ſtalks, with four ſpikes of flowers and a ſhrubby ſtalk.* Heliotropium arboreum maritimum, tomentoſum, gnaphalii Americani foliis. Sloan. Cat. 93. *Tree maritime woolly Heliotrope, with a Sea Cudweed leaf.*

9. HELIOTROPIUM (*Fruticoſum*) foliis lineari-lanceolatis piloſis, ſpicis ſolitariis ſeſſilibus. Lin. Sp. 187. *Heliotrope with linear, ſpear-ſhaped, hairy leaves, and ſingle ſpikes of flowers ſitting cloſe to the ſtalk.* Heliotropium minus lithoſpermi foliis. *Smaller Heliotrope with leaves like Gromwell.*

10. HELIOTROPIUM (*Procumbens*) caule procumbente, foliis ovatiis tomentoſis integerrimis, ſpicis ſolitariis terminalibus. *Heliotrope with a trailing ſtalk, oval, woolly, entire leaves, and ſingle ſpikes of flowers terminating the branches.* Heliotropium Americanum ſupinum & tomentoſum, foliis ſubrotundis. Houſt. MSS. *Low American woolly Heliotrope with roundiſh leaves.*

11. HELIOTROPIUM (*Americanum*) foliis oblongo-ovatis tomentoſis, ſpicis conjugatis terminalibus, caule fruticoſo. *Heliotrope with oblong, oval, woolly leaves, and double ſpikes of flowers terminating the ſtalk, which is ſhrubby.* Heliotropium Americanum fruteſcens & tomentoſum, foliis oblongis, floribus albis. Houſt. MSS. *Shrubby and woolly American Heliotrope, with oblong leaves and white flowers.*

The firſt ſort grows naturally in the ſouth of France, in Spain, Italy, and moſt of the warmer countries in Europe. It is an annual plant, which ſucceds better from ſeeds which ſcatter in the autumn, or ſown at that ſeaſon, than in the ſpring; for when they are ſown in the ſpring, they ſeldom come up the ſame year; but if the plant is once obtained, and the ſeeds ſuffered to ſhed, it will maintain itſelf without any trouble, requiring no other culture but to keep it clean from weeds, and thin the plants where they are too cloſe.

This riſes about ſeven or eight inches high, dividing into two or three branches, garniſhed with oval rough leaves, two inches long and one broad in the middle, of a light green, ſtanding upon pretty long foot-ſtalks alternately; the flowers are produced at the end of the branches in double ſpikes, joined at the bottom, which are about an inch and a half long, turning backward like a ſcorpion's tail. The flowers are white, and appear in June and July; the ſeeds ripen in autumn, ſoon after which the plant decays.

The ſecond ſort grows naturally in the Weſt-Indies. This is annual; the ſtalk riſes a foot and a half, or two feet high, branching out toward the top: the leaves are rough and hairy, ſtanding upon pretty long foot-ſtalks; they are two inches and a half long, and one and a half broad in the middle, ending in acute points; the flowers are produced toward the end of the branches in ſingle ſpikes, which are ſix inches long, turning backward at the top like the other ſpecies. The flowers are blue, and appear in July and Auguſt, the ſeeds ripen in September and October.

The third ſort grows naturally in the Weſt-Indies. This is a ſmaller plant than the former, ſeldom growing above two feet high; the leaves are one inch and a half long, and about half an inch broad; the ſpikes of flowers are very ſlender, and not more than two inches long; the flowers are ſmall, and of a light blue colour. They appear at the ſame time with the former, and the ſeeds ripen in autumn.

The ſeeds of theſe two ſorts muſt be ſown on a hot-bed in the ſpring, and when the plants are fit to remove, they muſt be tranſplanted on another hot-bed to bring them forward, treating them in the ſame way as the Balſamine, and other tender annual plants; and in June they may be taken up with balls of earth, and planted in the borders of the flower-garden, where they will flower, and in warm ſeaſons produce ripe ſeeds.

The fourth ſort riſes with a ſhrubby ſtalk ſix or ſeven feet high; the young branches are cloſely covered with a white down, and the leaves on thoſe are very hoary and entire, but thoſe on the older branches are greener, and ſome of them are notched on their edges; at each joint of the ſtalks come out two ſhort branches oppoſite, which are garniſhed with ſmall hoary leaves placed oppoſite: theſe, when bruiſed, emit a ſtrong odour, which to ſome perſons is very diſagreeable, but others are pleaſed with it. The plants rarely flower in England, for in near forty years which I have cultivated them, I have but once ſeen them in flower. The flowers are white, collected in roundiſh heads, which turn backward, and ſit cloſe to the branches;

the leaves continue all the year, for which the plants are preſerved in green-houſes, to add to the variety in winter.

The fifth ſort grows naturally in the Canary Iſlands. This riſes with a woody ſtalk three or four feet high, dividing into many branches, which are garniſhed with oval leaves notched on their edges, growing oppoſite upon long foot-ſtalks; they are hairy, and of an Aſh colour on their under ſide; the flowers are produced from the ſide of the branches on pretty long foot-ſtalks, each ſuſtaining four ſhort roundiſh ſpikes or heads, which divide by pairs, and ſpread from each other. The flowers are white, and appear in June and July, but are not ſucceeded by ſeeds in England. The leaves of this plant, when bruiſed, emit an agreeable odour, for which it is by ſome perſons much eſteemed; the gardeners have given it the title of Madam Maintenon, but for what reaſon I know not.

The two laſt ſorts are too tender to live through the winter in the open air in this country, ſo muſt be kept in a green-houſe during that ſeaſon; but they only require to be ſcreened from froſt, ſo may be placed with Myrtles and the other hardy green-houſe plants, where they may have a large ſhare of air in mild weather, and be treated in the ſame way; they are eaſily propagated by cuttings during any of the ſummer months, which, if planted in a ſhady border and duly ſupplied with water, will take root in five or ſix weeks; then they may be potted, and placed in a ſhady ſituation till they have taken new root, after which they may be treated as the old plants.

The ſixth ſort grows naturally in Peru, from whence the ſeeds were ſent by the younger Juſſieu to the Royal Garden at Paris, where the plants produced flowers and ſeeds; and from the curious garden of the Duke D'Ayen, at St. Germains, I was ſupplied with ſome of the ſeeds, which have ſucceeded in the Chelſea garden, where the plants have flowered and perfected their ſeeds for ſome years.

This riſes with a ſhrubby ſtalk two or three feet high, dividing into many ſmall branches, garniſhed with oval, ſpear-ſhaped, rough leaves, ſet on without order; they are three inches long, and one inch and a half broad in the middle, ſtanding on ſhort foot-ſtalks; they are hairy, and greatly veined on their under ſide, which is of an Aſh colour. The flowers are produced at the end of the branches in ſhort reflexed ſpikes, growing in cluſters. The foot-ſtalks divide into two or three, and theſe divide again into leſs, each ſuſtaining a ſpike of pale blue flowers, which have a ſtrong ſweet odour. The plants continue in flower great part of the year, and thoſe flowers which come out in ſummer, are ſucceeded by ripe ſeeds in autumn.

It may be propagated either by ſeeds or cuttings. The ſeeds ſhould be ſown upon a moderate hot-bed in the ſpring, and when the plants are fit to remove, they ſhould be tranſplanted into ſmall pots filled with light earth, and plunged into a hot-bed, where they ſhould be ſhaded till they have taken new root; then they ſhould be inured to the open air by degrees, into which they ſhould be removed in ſummer, placing them in a ſheltered ſituation; and in autumn they muſt be houſed with other exotic plants in a good green-houſe, where they will flower great part of winter, ſo will make a good appearance among the Orange-trees, and other green-houſe plants, with whoſe culture this plant will thrive. If the cuttings of this plant are put into pots filled with light earth, during any of the ſummer months, and plunged into a moderate hot-bed, they will take root very freely, but theſe do not make ſo good plants as thoſe raiſed from ſeeds.

The ſeventh ſort grows naturally on the ſea-ſhore in the Weſt-Indies; this is an annual plant, whoſe branches trail upon the ground, and grow a foot long; they are garniſhed with narrow grayiſh leaves, which are ſmooth. The flowers are produced in double ſpikes from the ſide of their branches; they are white and ſmall, ſo make no great appearance. It is propagated by ſeeds, and requires the ſame treatment as the ſecond and third ſorts.

The eighth ſort riſes with an upright woody ſtalk ſix or ſeven feet high, with a hoary bark, full of marks where the leaves have grown; the upper part of the ſtalk divides into two or three ſtrong woody branches, which grow erect, and are very cloſely garniſhed with long, narrow, woolly leaves, which ſtand on every ſide the branches without order. The flowers come out from the ſide of the ſtalks, to which they ſit cloſe; they are ſhort and reflexed, like thoſe of the other ſpecies. The flowers are purple, ſitting in very woolly empalements, which are divided into five ſegments, which ſpread open; the whole plant is very white and woolly, like the Sea Cudweed, ſo makes an odd appearance when intermixed with other exotic plants: this is propagated by ſeeds, which muſt be procured from the places where it naturally grows, for it never produces any in Europe; theſe ſeeds ſhould be ſown in a tub of earth in the country, for when the dried ſeeds come over they ſeldom grow; and if they do, it is not before the ſecond year: and from ſeveral parcels of the ſeeds which I have received from the Weſt-Indies, I have not raiſed more than two plants, and theſe came up from the ſeeds which had been ſown more than a year; ſo that if the ſeeds are ſown as ſoon as they are ripe in a tub of earth, when they arrive in England, the tub ſhould be plunged into a hot-bed of tanners bark, which will bring up the plants; and when theſe are fit to remove, they ſhould be each planted in a ſeparate ſmall pot filled with earth, compoſed of ſand and light undunged earth, with a little lime rubbiſh well mixed together, then plunged into a hot-bed of tanners bark, and ſhaded until they have taken new root; after which, they muſt be treated as other tender exotic plants, always keeping them in the tan-bed in the ſtove, giving them but little water, eſpecially during the winter ſeaſon.

The ninth ſort is a native of the Weſt-Indies, where it grows plentifully on the ſea-ſhore; it riſes with an upright ſhrubby ſtalk a foot and a half high, garniſhed with ſmall ſpear-ſhaped leaves, ſcarce one inch long, and one-third of an inch broad in the middle, ending in acute points, ſitting cloſe to the ſtalk; they are hoary on their under ſide, but ſmooth above. The flowers are produced in ſingle ſlender ſpikes, which come out from the ſide, and at the top of the ſtalks; they are but little recurved, eſpecially thoſe on the ſide, but thoſe at the top are more bent; they are white, ſo make but little appearance.

The tenth ſort was ſent me from Carthagena in New Spain, where it grows naturally on the ſandy ſhores. This is an annual plant, with trailing ſtalks which grow ſix or ſeven inches long, garniſhed with ſmall oval leaves, which are woolly and entire. The flowers are produced at the end of the branches, in ſingle ſhort ſpikes, which are reflexed; they are ſmall and white, ſo make little appearance.

The eleventh ſort was ſent me by the late Dr. Houſtoun from La Vera Cruz, where he found it growing in plenty; this riſes with a ſhrubby ſtalk three feet high, dividing into ſlender branches, which are cloſely garniſhed with oblong, oval, woolly leaves, placed without order. The flowers are produced at the end of the branches in double ſpikes, which are ſlender, ſhort, and ſtrait, not recurved as the other ſpecies. The flowers are ſmall and white, and the plant is perennial.

Theſe three laſt mentioned are propagated by ſeeds, but the difficulty of getting them freſh from America, and the uncertainty of their growing, unleſs they are ſown abroad, and brought over in earth, has rendered them rare in Europe; and as they are plants of little beauty, ſo few perſons have taken the trouble to procure them: beſides, as they require a ſtove to preſerve them in this country, and muſt have a peculiar ſoil and management like the eighth ſort, ſo, unleſs for the ſake of variety in botanic gardens, they are not worth cultivating here.

HELLEBORUS. Lin. Gen. Plant. 622. Tourn. Inſt. R. H. 271. tab. 144. [Ἑλλέβορος.] Black Hellebore, or Chriſtmas flower; in French, *Ellebore-Noire.*

The Characters are,

The flowers hath no empalement; it hath five large roundiſh petals, which are permanent, and many ſmall nectarii placed circularly, each being of one piece, with a narrow tube at the bottom, divided at the brim into two lips, the under being ſhort and indented; it hath a great number of ſtamina, terminated by compreſſed erect ſummits, and ſeveral germen, which are compreſſed, ſupporting awl-ſhaped ſtyles, crowned by thick ſtigmas. The germen afterward turn to compreſſed capſules with two keels, the lower being ſhort, and the upper convex, which are filled with round ſeeds adhering to the ſeam.

This genus of plants is ranged in the ſeventh ſection of Linnæus's thirteenth claſs, intitled Polyandria Polygynia, which includes thoſe plants whoſe flowers have many ſtamina and ſtyles.

The Species are,

1. Helleborus (*Fœtidus*) caule multifloro folioſo, foliis pedatis. Lin. Sp. Plant. 784. *Hellebore with many flowers on a ſtalk, which are intermixed with leaves, and ramoſe leaves ſitting on the foot-ſtalk.* Helleborus niger fœtidus. C. B. P. *Stinking Black Hellebore, Bears-foot, or Setterwort.*
2. Helleborus (*Viridis*) caule multifloro folioſo, foliis digitatis. Lin. Sp. Plant. 558. *Hellebore with many flowers on a ſtalk, which are intermixed with leaves, and hand-ſhaped leaves.* Helleborus niger hortenſis, flore viridi. C. B. P. *Green flowered Black Hellebore, or Bears-foot.*
3. Helleborus (*Niger*) ſcapo ſub-unifloro ſub-nudo, foliis pedatis. Hort. Upſal. 157. *Hellebore with one flower on a ſtalk, which is naked, and hand-ſhaped leaves ſitting on the foot-ſtalk.* Helleborus niger, flore albo, etiam interdum valde rubente. J. B. *True Black Hellebore, or Chriſtmas Roſe.*
4. Helleborus (*Trifolius*) caule multifloro, foliis ternatis integerrimis. *Hellebore with many flowers on a ſtalk, and leaves compoſed of three entire lobes.* Helleborus niger trifoliatus. Hort. Farn. *Trifoliate Black Hellebore.*
5. Helleborus (*Hyemalis*) flore folio inſidente. Hort. Cliff. 227. *Hellebore with the flower ſitting on the leaf.* Aconitum Hyemale, *or Winter Aconite.*
6. Helleborus (*Latifolius*) caule multifloro folioſo, foliis digitatis ſerratis amplioribus. *Hellebore with many flowers upon a ſtalk, intermixed with leaves, and large fingered leaves which are ſawed.* Helleborus niger amplioribus foliis. Tourn. Inſt. R. H. 272. *Black Hellebore with larger leaves.*

The firſt ſort grows naturally in woods in ſeveral parts of England, but particularly in Suſſex, where I have ſeen it in great plenty; this hath a jointed herbaceous ſtalk, which riſes two feet high, dividing into two or three heads, garniſhed with leaves compoſed of eight or nine long narrow lobes, which join at their baſe; four of theſe on each ſide are joined together at their tails, and the middle one ſtands on the center of the foot-ſtalk; theſe are ſawed on their edges, and end in acute points; thoſe on the lower part of the ſtalk are much larger than the upper, which are ſmall and narrow. The flower-ſtalk ariſes from the center of the plant, dividing into many branches, each ſuſtaining ſeveral ſmaller foot-ſtalks, with one entire ſpear-ſhaped leaf upon each, and one large greeniſh flower at the top with purpliſh rims; theſe appear in winter, and the ſeeds ripen in the ſpring; which, if permitted to ſcatter, the plants will riſe without care, and may be tranſplanted into woods, or in wilderneſs quarters, where they will grow in great ſhade, and make a good appearance at a ſeaſon when there are but few plants in beauty.

The ſecond ſort grows naturally at Ditton, near Cambridge, and in the woods near Stoken Church, in Oxfordſhire. The ſtalks of this ſort grow more upright than thoſe of the firſt, and do not branch ſo much. The leaves are compoſed of nine long lobes, which unite to the foot-ſtalk at their baſe, and are ſharply ſawed on their edges; they are of a lighter green than thoſe of the firſt ſort. The flowers are produced at the top of the ſtalk, having one or two leaves ſet on the foot-ſtalk; they are compoſed of five oval green petals, with a great number of ſtamina ſurrounding the germen in the middle; theſe appear the beginning of February, and the ſeeds ripen the end of May, which if ſown ſoon after they are ripe, the plants will come up early the following ſpring; and, when they have obtained ſtrength, may be planted in ſhady places under trees, where they will thrive and flower very well. The leaves of this ſort decay in autumn, and new ones ariſe from the roots in the ſpring, but the firſt ſort is always green.

The third ſort is ſuppoſed to be the Hellebore of the antients; this grows naturally on the Alps and Apennine mountains. The root of this ſort is compoſed of many thick fleſhy fibres, which ſpread far into the ground, from which ariſe the flowers upon naked foot-ſtalks, immediately from the root, each ſupporting one large white flower, compoſed of five roundiſh petals, with a great number of ſtamina in the middle. The leaves of this are compoſed of ſeven or eight thick, fleſhy, obtuſe lobes, which are ſlightly ſawed on their edges, and unite with the foot-ſtalk at their baſe; this plant flowers in winter, from whence the title of Chriſtmas Roſe was applied to it: it is propagated by parting of the roots in autumn, for the ſeeds ſeldom ripen well in England; it ſhould have a more ſheltered ſituation than either of the former, otherwiſe it will not flower well.

The fourth ſort is like the ſecond, but differs from it in having trifoliate leaves, which are broader and entire, their ſurface is ſmoother; this flowers early in winter, and the ſtalks riſe higher than either of the former ſorts, but is at at preſent rare in England.

The fifth ſort is the common Winter Aconite, which is ſo well known as to need no deſcription. It flowers very early in the ſpring, which renders it worthy of a place in all curious gardens, eſpecially as it requires but little room; this is propagated by offſets, which the roots ſend out in plenty; theſe roots may be taken up and tranſplanted, any time after their leaves decay, which is generally by the beginning of June till October, when they will begin to put out new fibres; but as the roots are ſmall, and nearly of the colour of the ground, ſo, if care is not taken to ſearch them, many of the roots will be left in the ground; theſe roots ſhould be planted in ſmall cluſters, otherwiſe they will not make a good appearance; for ſingle flowers ſcattered about the borders of theſe ſmall kinds, are ſcarce ſeen at a diſtance; but when theſe and the Snowdrops are alternately planted in bunches, they will have a good effect, as they flower at the ſame time, and are much of a ſize.

The ſixth ſort is like the firſt, but the lobes of the leaves are broader, and the ſtalks grow taller; this grows naturally in Iſtria and Dalmatia, from whence I received ſome of the ſeeds; it has been ſuppoſed to be only a ſeminal variety of the firſt, and as ſuch I ſowed the ſeeds; but the plants had a very great difference, and the firſt winter proving ſevere, they were all deſtroyed; ſo that it is not ſo hardy as our common ſort, and depending on their being ſo, occaſioned the loſs of the plants.

HELLEBORUS flore globoſo. See TROLLIUS.

HELLEBORUS ALBUS. See VERATRUM.

HELMET FLOWER, or MONK's HOOD. See ACONITUM.

HEMEROCALLIS. Lin. Gen. Plant. 391. Lilio-Aſphodelus. Tourn. Inſt. R. H. 344. tab. 179. Liliaſtrum. Tourn. Inſt. R. H. 369. tab. 194. *Lily Aſphodel, or Day Lily*; in French, *Lis de Saint Bruno.*

The CHARACTERS are,

The flower has no empalement; in ſome ſpecies the flower is of one petal, cut into ſix parts; in others it hath ſix petals, with a ſhort tube, ſpreading open at the top, which is reflexed. There are ſix awl-ſhaped declining ſtamina ſurrounding the ſtyle, terminated by oblong proſtrate ſummits. The roundiſh furrowed germen is ſituated in the middle, ſupporting a ſlender ſtyle, crowned by an obtuſe three-cornered ſtigma. The germen afterward becomes an oval three-cornered capſule with three lobes, opening with two valves, filled with roundiſh ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's ſixth claſs, which includes the plants whoſe flowers have ſix ſtamina and one ſtyle. Tournefort places the firſt in the firſt ſection of his ninth claſs, which includes the plants with a Lily-flower of one leaf, cut into ſix parts, whoſe pointal becomes the fruit; the ſecond he places in his fourth ſection of the ſame claſs, with the flowers of the ſame form which have ſix petals.

The SPECIES are,

1. HEMEROCALLIS (*Flava*) corollis flavis. Lin. Sp. 462. Hort. Upſal. 88. *Day Lily with a yellow flower.* Lilio-Aſphodelus luteus. Park. Par. 148. *Yellow Aſphodel Lily.*
2. HEMEROCALLIS (*Minor*) ſcapo compreſſo corollis monopetalis campanulatis. *Day Lily with a compreſſed ſtalk, and a bell-ſhaped flower of one petal.* Lilio-Aſphodelus luteus, minor. Tourn. Inſt. R. H. 344. *Smaller yellow Aſphodel Lily.*
3. HEMEROCALLIS (*Fulva*) corollis fulvis. *Day Lily with a copper-coloured flower.* Lilio-Aſphodelus phœnicius. Park. Par. 148: *Aſphodel Lily with a reddiſh flower.*
4. HEMEROCALLIS. (*Liliaſtrum*) ſcapo ſimplici, corollis hexapetalis campanulatis. Hort. Cliff. 128. *Day Lily with an unbranched ſingle ſtalk, and bell-ſhaped flowers with ſix petals.* Liliaſtrum Alpinum majus. Tourn. Inſt. R. H. 369. *Greater Alpine Baſtard Lily, called Savoy Spiderwort*; and in French, *Lis de Saint Bruno, i. e. St. Bruno's Lily.*

The firſt ſort grows naturally in Hungary, Dalmatia, and Iſtria, but has long been an inhabitant in the Engliſh gardens; this hath ſtrong fibrous roots, to which hang knobs, or tubers, like thoſe of the Aſphodel, from which come out keel-ſhaped leaves, which are two feet long, with a rigid midrib, the two ſides drawing inward, ſo as to form a ſort of gutter on the upper ſide. The flower-ſtalks riſe two feet and a half high, having two or three longitudinal furrows; theſe are naked, and at the top divide into three or four ſhort foot-ſtalks, each ſuſtaining one pretty large yellow flower ſhaped like a Lily, having but one petal, with a ſhort tube, ſpreading open at the brim, where it is divided into ſix parts; theſe have an agreeable ſcent, from which ſome have given it the title of yellow Tuberoſe. It flowers in June, and the ſeeds ripen in Auguſt; this plant is eaſily propagated by offſets, which the roots ſend out in plenty; theſe may be taken off in autumn, that being the beſt ſeaſon for tranſplanting the roots, and planted in any ſituation, for they are extremely hardy, and will require no other culture but to keep them clean from weeds, and to allow them room that their roots may ſpread; they may alſo be propagated by ſeeds, which, if ſown in autumn, the plants will come up the following ſpring, and theſe will flower in two years; but if the ſeeds are not ſown till ſpring, the plants will not come up till the year after.

The ſecond ſort grows naturally in Siberia; this hath roots like thoſe of the former ſort, but are ſmaller. The leaves are not near ſo long, nor more than half the breadth of the former, and of a dark green colour. The flower-ſtalk riſes a foot and a half high, is naked and compreſſed, but has no furrows; at the top is produced two or three yellow flowers, which are nearer the bell-ſhape than thoſe of the other ſpecies, and ſtand on ſhorter foot-ſtalks; theſe flower the beginning of June, and the ſeeds ripen early in Auguſt. It is propagated by offſets from the root, or by ſeeds, in the ſame manner as the former, but the roots do not increaſe ſo faſt; it ſhould have a moiſt ſoil and a ſhady ſituation, where it will thrive much better than in dry ground.

The third ſort is a much larger plant than either of the former, and the roots ſpread and increaſe much more, therefore is not proper furniture for ſmall gardens; the roots of this hath very ſtrong fleſhy fibres, to which hang large oblong tubers. The leaves are near three feet long, hollowed like thoſe of the former, turning back toward the top. The flower-ſtalks are as thick a man's finger, and riſe near four feet high; they are naked, without joints, and branching at the top, where are ſeveral large copper-coloured flowers, ſhaped like thoſe of the Red Lily, and as large. The ſtamina of this ſort are longer than thoſe of the other, and their ſummits are charged with a copper-coloured farina, which ſheds on being touched; or if a perſon ſmells to the flowers, it will fly off and ſpread over the face, dyeing it all over of a copper colour, which is a trick often played by ſome unlucky people to the ignorant: theſe flowers never continue longer than one day, but there is a ſucceſſion of flowers on the ſame plants for a fortnight or three weeks; this ſort flowers about the ſame time as the former, and the roots propagate too faſt for thoſe gardens where there is but little room. It will grow on any ſoil or in any ſituation; the beſt time to tranſplant the roots is in autumn.

The Savoy Spiderwort, or, as the French call it, St. Bruno's Lily, is a plant of humbler growth than either of the former: there are two varieties of this, one is titled Liliaſtrum Alpinum majus, and the other Liliaſtrum Alpinum minus by Tournefort; the firſt of theſe riſes with a flower-ſtalk more than a foot and a half high; the flowers are much larger, and there is a greater number upon each ſtalk than the ſecond; but as there is no other eſſential difference between them, I have not put them down as different ſpecies; but the firſt is by much the finer plant, though not common in England, for the ſecond ſort is what I have always obſerved in the gardens here. I received ſome roots of the ſecond ſort from Monſ. Richard, gardener to the King of France, which continue their difference in the ſame ſoil and ſituation with the firſt, which flowers earlier in the year; the leaves of this ſort are ſomewhat like thoſe of the Spiderwort, are pretty firm, and grow upright; the flower-ſtalks grow about a foot and a half high, and have ſeveral white flowers at the top, ſhaped like thoſe of the Lily, which hang on one ſide, and have an agreeable ſcent; theſe are but of ſhort duration, ſeldom continuing in beauty above three or four days; but when the plants are ſtrong, they will produce eight or ten flowers upon each ſtalk, ſo they make a good appearance while they laſt.

This ſort is uſually propagated by parting the roots; autumn is the beſt ſeaſon for doing this work, as it alſo is for tranſplanting the roots; for when they are removed in the ſpring, they ſeldom flower the ſame year, or if they do, it is but weakly: theſe plants ſhould not be tranſplanted oftener than every third year, when the roots may be parted to make an increaſe of the plants, but they ſhould not be divided too ſmall; for if they are, it will be two years before they flower: theſe plants delight in a light loamy ſoil and in an open expoſure, ſo muſt not be planted under the drip of trees; but if they are planted to an eaſt aſpect, where they may be protected from the ſun in the heat of the day, they will continue in beauty longer than when they are more expoſed.

HEMIONITIS [Ἡμιονῖτις, of Ἡμίονος, a Mule, q. d. Mulewort, becauſe this plant was believed to be as barren as a mule.] Moonfern.

This is a plant which is ſeldom propagated in gardens, therefore I ſhall not trouble the reader with any account of it more than this. That whoever hath a mind to cultivate any of the ſorts, muſt procure the plants from the countries where they naturally grow; there are two ſorts which are natives of the warmer parts of Europe, but in America there is a great number of very different kinds; theſe muſt be planted in pots filled with loamy undunged earth, and ſuch of them as are natives of hot countries, muſt be placed in the ſtove; the others may be ſheltered under a common frame in winter, and during the ſummer they muſt be frequently watered, but in winter they will require but little. In ſummer they ſhould alſo have plenty of free air admitted to them; with this management the plants will thrive.

HEPATICA. Boerh. Ind. Plant. Ranunculus. Tourn. Inſt. R. H. 286. Anemone. Lin. Gen. Plant. 614. [Ἡπατῖτις, of Ἧπαρ, the liver, ſo called, becauſe the leaves of this plant are divided into lobes, like the liver (but it does not at all take its name from its uſe, for it is of no virtue againſt the diſeaſes of the liver, as many have erroneouſly imagined;) and trifolia, from its ſimilitude thereto.] Hepatica, or Noble Liverwort.

The Characters are,

The flower hath a three-leaved empalement. It hath ſix petals, which are oval, and expand to the bottom, with a great number of ſlender ſtamina ſhorter than the petals, terminated by obtuſe ſummits; and ſeveral germen collected into a head, ſupporting acuminated ſtyles, crowned by obtuſe ſtigmas. The germen afterward turns to acuminated ſeeds ſitting round the ſtyles.

This genus of plants is by Tournefort ranged among the Crowfoots, and by Linnæus it is placed under Anemone; but as the flowers of Anemone have no empalement, and the Hepatica hath a three-leaved one, it may be ſeparated from that genus; and as it is well known in the gardens by this title, ſo ſhould we range it with the Anemone, it might occaſion confuſion. This is ranged in the ſeventh ſection of Linnæus's thirteenth claſs, which includes the herbs with flowers having many ſtamina and ſtyles.

The Varieties of this plant are,

1. Hepatica (*Nobilis*) trifolio, cœruleo flore. Cluſ. *The ſingle blue Hepatica, or Noble Liverwort.*
2. Hepatica (*Plena*) trifolia cœruleo pleno. Cluſ. *The double blue Hepatica, or Noble Liverwort.*
3. Hepatica (*Alba*) trifolia, flore alba ſimplici. Boerh. Ind. *The ſingle white Hepatica, or Noble Liverwort.*
4. Hepatica (*Vulgaris*) trifolia, rubro flore. Cluſ. *Single red Hepatica, or Noble Liverwort.*
5. Hepatica (*Rubra*) trifolia, flore rubro pleno. Boerh. Ind. *Double red, or Peach-coloured Hepatica.*

Theſe plants are ſome of the greateſt beauties of the ſpring; the flowers are produced in February and March in great plenty, before the green leaves appear, and make a very beautiful figure in the borders of the pleaſure-garden, eſpecially the double ſorts, which commonly continue a fortnight long in flower than the ſingle kinds, and the flowers are much fairer. I have ſeen the double white kind often mentioned in books, but could never ſee it growing, though I do not know but ſuch a flower might be obtained from ſeeds of the ſingle white, or blue kinds. I have ſometimes known the double blue ſort produce ſome flowers in autumn, which were inclining to white, and thereby ſome people have been deceived, who have procured the roots at that ſeaſon, and planted them in their gardens; but the ſpring following their flowers were blue, as before; and this is what frequently happens, when the autumn is ſo mild as to cauſe them to flower; but whether the double white ſort, mentioned in the books, was only this accidental alteration in the colour of the flower, I cannot ſay, though it ſeems very probable it was, ſince I never could hear of any perſon who ever ſaw the double white ſort flower in the ſpring.

The ſingle ſorts produce ſeeds every year, whereby they are eaſily propagated, and alſo new flowers may be that way obtained. The beſt ſeaſon for ſowing of the ſeeds is in the beginning of Auguſt, either in pots or boxes of light earth, which ſhould be placed ſo as to have only the morning ſun until October, when they ſhould be removed into the full ſun, to remain during the winter ſeaſon; but in March, when the young plants will begin to appear, they muſt be removed again to a ſhady ſituation, and in dry weather ſhould be frequently watered, and about the beginning of Auguſt they will be fit to be tranſplanted; at which time you ſhould prepare a border facing the eaſt, of good, freſh, loamy earth, into which you ſhould remove the plants, placing them about ſix inches diſtance each way, cloſing the earth pretty faſt to their roots, to prevent the worms from drawing them out of the ground, which they are very apt to do at that ſeaſon; and, in the ſpring following, they will begin to ſhew their flowers; but it will be three years before they flower ſtrong, and till then you cannot judge of their goodneſs; when, if you find any double flowers, or any of a different colour from the common ſorts, they ſhould be taken up, and tranſplanted into the borders of the flower-garden, where they ſhould continue at leaſt two years before they are taken up or parted; for it is remarkable in this plant, that where they are often removed and parted, they are very ſubject to die; whereas, when they are permitted to remain undiſturbed for many years, they will thrive exceedingly, and become very large roots.

The double flowers, which never produce ſeeds, are propagated by parting their roots, which ſhould be done in March, at the time when they are in flower; but you ſhould be careful not to ſeparate them into very ſmall heads, nor ſhould they be parted oftener than every third or fourth year, if you intend to have them thrive, for the reaſon before given. They delight in a ſtrong loamy ſoil, and in an eaſtern poſition, where they may have only the morning ſun, though they will grow in almoſt any aſpect, not too warm, and are never injured by cold.

HEPATORIUM. See Eupatorium.

HEPTAPHYLLUM. See Potentilla.

HERACLEUM. Lin. Gen. 345. Sphondylium. Tourn. Inſt. 1. Cow Parſnep.

The Characters are,

The calyx of the greater umbel is large, compoſed of many ſmaller, which are plain; the general involucrum is compoſed of many leaves which fall off; the partial umbels have involucrums of three to ſeven leaves, the outer being the longeſt. The general umbel is deformed, the florets are moſtly fruitful; thoſe of the diſk have five equal petals, which are inflexed; thoſe of the rays have the ſame number of unequal petals, the outer being the largeſt; they have each five ſtamina longer than the petals, terminated by ſmall ſummits. The germen is ſituated under the flower, and is almoſt oval, ſupporting two ſtyles, crowned by ſimple ſtigmas. The germen afterward becomes an elliptical fruit, compoſed of two oval compreſſed ſeeds.

This genus of plants is ranged in the ſecond order of Linnæus's fifth claſs, intitled Pentandria Digynia, the flowers having five ſtamina and two ſtyles.

The Species are,

1. Heracleum (*Sphondylium*) foliolis pinnatifidis. Hort. Cliff. 103. *Cow Parſnep with wing-pointed leaves.* Sphondylium vulgare hirſutum. C. B. P. 157. *Common Cow Parſnep.*
2. Heracleum (*Panaces*) foliis pinnatis, foliolis quinis, intermediis ſeſſilibus, floribus radiatis. Hort. Upſal. 65. *Cow Parſnep with winged leaves having five lobes, and radiated flowers.* Panax Sphondylii folio, ſc. Heracleum, C. B. P. 157.
3. Heracleum (*Alpinum*) foliis ſimplicibus, floribus radiatis. Lin. Sp. 359. *Cow Parſnep with ſimple leaves and radiated flowers.* Sphondylium Alpinum glabrum. C. B. P. 157. *Smooth Alpine Cow Parſnep.*
4. Heracleum (*Sibricum*) foliis pinnatis, folioliis quinis, intermediis ſeſſilibus, corollulis uniformibus. Hort. Upſal. 65. *Cow Parſnep with winged leaves, having five lobes*

lobes and a uniform corolla. Paſtinaca foliis ſimpliciter pinnatis, foliolis pinnafidis. Flor. Siber. 1. p. 218.

The firſt ſort grows naturally in moſt parts of England, ſo is rarely admitted into gardens; there is a variety (if not a diſtinct ſpecies of this) with narrower leaves, which are more divided than thoſe of the firſt; however, as they are ſeldom cultivated, I ſhall not trouble the reader with their deſcription.

The ſecond ſort is placed in moſt of the Pharmacopœias as a medicinal plant, but is rarely uſed as ſuch, eſpecially in England. This riſes with a tall ſtalk near ſix feet high, which is embraced by the baſe of the leaves; theſe are winged, having generally five roundiſh lobes, whoſe ſurface is rough, of a dark green colour: the flowers are produced at the top of the ſtalks, being cloſely incloſed by the empalement when they firſt appear; but this afterward burſting, the umbel expands, having large petals on their exterior row, which are almoſt heart-ſhaped, and are ſucceeded by flat compreſſed ſeeds like thoſe of Parſnep, but larger, having black ſtreaks on their outſide. This grows naturally on the Appenines.

The third ſort grows naturally on the Alps, as alſo in Siberia: the ſtalks of this riſe as high as thoſe of the former, but the leaves are ſmooth. This is ſeldom cultivated.

The fourth ſort grows naturally in Siberia and Tranſylvania; in the former country, the inhabitants eat the ſtalks and leaves of the plant for want of better food.

As theſe plants are rarely cultivated, unleſs in botanic gardens, ſo I ſhall recommend to thoſe who are deſirous to propagate either of the ſpecies, to ſow their weeds in the autumn; and in the ſpring, when the plants are up, to hough the ground, cutting up the ſeeds, and thinning of the plants, in the ſame manner as is directed for Parſneps, with which culture the plants will thrive.

HERBA GERARDI. See ANGELICA SYLVESTRIS MINOR.

HERBALIST, HERBARIST, a perſon who is ſkilled in diſtinguiſhing the kinds, natures, or virtues of herbs or plants.

To **HERBARIZE,** to go abroad in the fields in queſt of different or new herbs or plants.

HERBIFEROUS ſignifies bearing or bringing forth herbs.

HERBIVOROUS, i. e. devouring or feeding on herbs or Graſs.

HERBOSE, graſſy, or full of Graſs or herbs.

HERBOSITY, graſſineſs, or abundance of Graſs or herbs.

HERBULENT, graſſy, full of Graſs or herbs.

HERMANNIA. Tourn. Inſt. R. H. 656. tab. 432. Lin. Gen. Plant. 742. The title of this genus was given by Dr. Tournefort in honour of that great botaniſt, Paul Herman, M. D. Profeſſor of Botany at Leyden.

The CHARACTERS are,

The flower hath a pitcher-ſhaped permanent empalement, divided into five parts at the brim. It hath five petals, which are narrow at their baſe, and twiſt againſt the ſun within the tubulous empalement, but ſpread open above, where they are broad and obtuſe. It hath five broad ſtamina, which are joined in one body, terminated by pointed ſummits, which are joined. In the center is ſituated a roundiſh five-cornered germen, ſupporting an awl-ſhaped ſtyle which is longer than the ſtamina, crowned by a ſingle ſtigma. The germen afterward becomes a five-cornered roundiſh capſule, with five cells opening at the top, incloſing many ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's ſixteenth claſs, which includes the plants whoſe flowers have five ſtamina joined in one body to the ſtyle.

The SPECIES are,

1. HERMANNIA (*Alnifolia*) foliis cuneiformibus plicatis, crenato-emarginatis. Hort. Cliff. 342. *Hermannia with wedge-ſhaped folded leaves, which are crenated and indented.* Hermannia fruteſcens, folio oblongo ſerrato latiori. Boerh. Ind. *Shrubby Hermannia with a broader, oblong, ſerrated leaf.*
2. HERMANNIA (*Groſſulariæfolia*) foliis obovatis acute inciſis, pedunculis bifloris. Prod. Leyd. 347. *Hermannia with oval leaves acutely cut, and foot-ſtalks having two flowers.* Hermannia fruteſcens folio groſſulariæ parvo hirſuto. Boerh. Ind. *Shrubby Hermannia with a ſmall, hairy, Gooſeberry leaf.*
3. HERMANNIA (*Althææfolia*) foliis obovatis plicatis crenatis tomentoſis Hort. Cliff. 343. *Hermannia with oval, folded, woolly leaves, which are crenated* Hermannia fruteſcens, folio ibiſci hirſuto molli, caule piloſo. Boerh. Ind. *Shrubby Hermannia with a ſoft, hairy, Marſhmallow leaf, and woolly ſtalk.*
4. HERMANNIA (*Hyſſopifolia*) foliis lanceolatis obtuſis ſerratis. Hort. Cliff. 342. *Hermannia with obtuſe ſpear-ſhaped leaves, which are ſawed.* Hermannia fruteſcens, folio oblongo ſerrato. Tourn. *Shrubby Hermannia with an oblong ſerrated leaf.*
5. HERMANNIA (*Trifoliato*) foliis oblongo-ovatis crenatis tomentoſis flore mutabili. *Hermannia with oblong, oval, crenated woolly leaves, and a changeable flower.* Hermannia fruteſcens, folio oblongo molli cordato hirſuto. Boerh. Ind. *Shrubby Hermannia with a ſoft, oblong, hairy, heart-ſhaped leaf.*
6. HERMANNIA (*Pinnata*) foliis tripartitis, media pinnatifida. Hort. Cliff. *Hermannia with tripartite leaves ending in many points.* Hermannia fruteſcens, folio multifido tenui, caule rubro. Boerh. Ind. alt. *Shrubby Hermannia with a narrow multifid leaf, and a red ſtalk.*
7. HERMANNIA (*Lavendulifolia*) foliis lanceolatis obtuſis integerrimis. Hort. Cliff. 342. *Hermannia with obtuſe ſpear-ſhaped leaves, which are entire.* Hermannia fruteſcens, folio lavendulæ latiori & obtuſo, flore parvo aureo. Boerh. Ind. alt. *Shrubby Hermannia with a broad, blunt, Lavender leaf, and a ſmall golden flower.*
8. HERMANNIA (*Hirſuta*) foliis ſimplicibus ternatiſque hirſutis ſeſſilibus. *Hermannia with ſingle and trifoliate leaves which are hairy, and ſit cloſe to the ſtalk.*

The firſt ſort riſes with a ſhrubby ſtalk ſix or eight feet high, dividing into many erect irregular branches, covered with a brown bark, garniſhed with wedge-ſhaped leaves, which are narrow at their baſe, but broad and round at the top; they are about an inch long, and three quarters broad at the point, where they are indented and crenated. The flowers are produced in ſhort ſpikes on the upper part of the branches; they are of a pale yellow colour, but ſmall; theſe appear in April and May, and are often ſucceeded by ſeeds, which ripen in Auguſt.

The ſecond ſort is a ſhrub of lower ſtature than the firſt, but ſends out a great number of branches, which ſpread wide on every ſide, garniſhed with ſmaller leaves than thoſe of the former, which are rough, and ſit cloſe to the branches. The flowers are produced in ſhort cloſe ſpikes at the end of every ſhoot, ſo that the whole ſhrub ſeems covered with flowers; they are of a bright yellow, and appear toward the end of April, but are not ſucceeded by ſeeds in England.

The third ſort is a plant of humbler growth than either of the former, ſeldom riſing more than two feet and a half high; the ſtem is not ſo woody, and the branches are ſoft and ſlender, garniſhed with oval woolly leaves, which are plaited and crenated on the edges; the flowers are produced in looſe panicles at the end of the branches; they are larger than thoſe of the other ſpecies, and have very hairy empalements. This ſort flowers in June and July, and frequently puts out more in the autumn.

The fourth ſort has been longer in the European gardens than either of the other. This riſes with a ſhrubby upright ſtalk to the height of ſeven or eight feet, ſending out many ligneous branches from the ſide, which alſo grow more erect than any of the other; theſe are cloathed with obtuſe ſpear-ſhaped leaves, about an inch and a half long, and half an inch broad, ſawed on the edges toward the end: the flowers come out in ſmall bunches from the ſide of the ſtalk; they are of a pale Straw colour, and appear in May and June; theſe are frequently ſucceeded by ſeeds, which ripen the latter part of Auguſt.

The fifth ſort ſeldom riſes more than two feet high, with a ſoft ligneous ſtalk, ſending out ſlender irregular branches, garniſhed with oblong, oval, woolly leaves, ſtanding upon pretty long footſtalks; the flowers are produced in looſe ſpikes at the end of the branches; theſe are, at their firſt appearance, of a gold colour, but after they have been ſome days open, they change to yellow. This flowers in June and July.

The ſixth ſort riſes with a ſhrubby ſtalk near three feet high, ſending out many ſlender branches, covered with a reddiſh bark, garniſhed with narrow wing-pointed leaves; the flowers come out from the ſide of the branches in ſmall cluſters; they are ſmall, and of a deep yellow colour. This flowers in June and July.

The ſeventh ſort hath ſhrubby branching ſtalks, which are very buſhy, but ſeldom riſe more than a foot and a half high; the branches are very ſlender, and garniſhed with hairy, pale, green leaves of different ſizes; ſome of them are two inches long, and one broad at their ends; but their common ſize is ſeldom more than one inch long, and half an inch broad at their points; they are entire, and ſit pretty cloſe to the branches; the flowers come out from the ſide of the ſtalk ſingly, they are ſmall, and of a yellow colour. This ſort flowers moſt part of ſummer.

The eighth ſort I raiſed from ſeeds which came from the Cape of Good Hope. This riſes with a ſhrubby hairy ſtalk about two feet high, ſending out many ſide branches, which grow more erect than thoſe of the former, garniſhed with oblong, veined, hairy leaves, which are ſometimes ſingle, and at other times come out by threes, the middle one being the largeſt; the flowers are produced toward the end of the branches; they are large, and of a deep yellow colour, with large, ſwollen, hairy empalements. This ſort continues flowering moſt part of ſummer.

All the ſpecies of this genus yet known, are natives of the country about the Cape of Good Hope, from whence moſt of them were brought to the gardens in Holland, where they have been propagated and ſpread through moſt parts of Europe.

The plants are all propagated by planting cuttings of them during any of the ſummer months, in a bed of freſh earth, obſerving to water and ſhade them until they are well rooted, which will be in about ſix weeks after planting; then you ſhould take them up, preſerving a ball of earth to their roots, and plant them into pots filled with light freſh earth, placing them in a ſhady ſituation until they have taken freſh root; after which they may be expoſed to the open air, with Myrtles, Geraniums, &c. until the middle or latter end of October, when they muſt be removed into the green-houſe, obſerving to place them in the cooleſt part of the houſe, where they may have as much free air as poſſible; for if they are too much drawn in the houſe, they will appear very faint and ſickly, and ſeldom produce many flowers; whereas, when they are only preſerved from the froſt, and have a great ſhare of free air, they will appear ſtrong and healthy, and produce large quantities of flowers in April and May, during which ſeaſon they make a very handſome appearance in the green-houſe: they muſt alſo be frequently watered, and will require to be new potted at leaſt twice every year, i. e. in May and September; otherwiſe their roots will be ſo matted, as to prevent their growth.

Theſe plants rarely produce good ſeeds with us, except the fourth and eighth ſorts, which ripen their ſeeds every year in England; the other rarely producing any, I ſuppoſe this may be accounted for by their having been long propagated from cuttings; for thoſe plants which I have raiſed from ſeeds, have been fruitful two or three years after, but I have always found thoſe plants which have been propagated by cuttings taken from theſe, have ſoon become barren: the ſame thing I have obſerved in many other plants, therefore thoſe who are deſirous to continue their plants fruitful, ſhould conſtantly raiſe them from ſeeds. Theſe, as alſo thoſe which are obtained from abroad, muſt be ſown upon a moderate hot-bed; and when the plants come up, they muſt be tranſplanted into ſmall pots, and plunged into another very moderate hot-bed, in order to promote their rooting; after which they muſt be hardened by degrees, to endure the open air in ſummer, and may then be treated as the old plants.

HERMODACTYLUS, the Hermodactyl, commonly called Snake's-head Iris.

This genus is by Dr. Linnæus joined to Iris, the characters of the flower agreeing pretty well with thoſe of that genus; from which Tournefort has ſeparated it from the difference of the root, which is not according to his own ſyſtem, where he makes the ſhape of the petals with their number and poſition, the principal characteriſtics in diſtinguiſhing the claſſes and genera; but as this plant requires a particular treatment, ſo I have continued it under Tournefort's title.

The CHARACTERS are,

It hath a Lily-ſhaped flower, conſiſting of one leaf, and ſhaped exactly like an Iris, but has a tuberous root, divided into two or three dugs, like oblong bulbs.

We have but one SPECIES of this plant, viz.

HERMODACTYLUS (*Tuberoſa*) folio quadrangulo. C. B. P. *Snake's-head Iris*, vulgò. This is alſo called Iris tuberoſa Belgarum, i. e. *Tuberous Iris of the Dutch.*

This plant is eaſily propagated by its tubers, which ſhould be taken off ſoon after the green leaves decay, which is the proper ſeaſon for tranſplanting the root; but they ſhould not be kept long out of the ground, leſt they ſhrink, which will cauſe them to rot when they are planted. They ſhould have a loamy ſoil, not too ſtrong nor deep, and muſt be planted to an eaſt aſpect, where they will flower very well. The roots ſhould not be removed oftener than once in three years, if you deſign to increaſe them; but then they ſhould be planted at a farther diſtance from each other, than if they were to remain but one year; and the beds ſhould be kept clear from weeds, and at Michaelmas there ſhould be ſome fine earth laid over the beds, which will greatly ſtrengthen their roots. The diſtance which theſe plants ſhould be allowed is ſix inches ſquare, and they ſhould be placed three inches deep in the ground. Theſe produce their flowers in May, and their ſeeds are ripe in Auguſt; but as they multiply pretty faſt by their roots, few people are at the trouble of raiſing them from ſeeds; but thoſe who have an inclination ſo to do, muſt treat them in the manner directed for the bulbous Iriſes.

The roots of this plant are very apt to run deep into the ground, and then they ſeldom produce flowers; and many times they ſhoot ſo deep as to be loſt, eſpecially where the ſoil is very light; therefore to prevent this, it will be proper to lay a thickneſs of rubbiſh under the border where theſe are planted, to hinder them from getting down. This ſhould always be practiſed in light ground, but in ſtrong land there will be no occaſion to make uſe of this precaution, becauſe they do not ſhoot downward ſo freely in that.

This plant has by ſome botanic writers been ſuppoſed the true Hermodactyl, but what has been long uſed in Europe for that is the root of a Colchicum.

HERNANDIA. Plum. Nov. Gen. 8. tab. 40. Lin. Gen. Plant. 931. Jack-in-a-Box, vulgò.

The CHARACTERS are,

It hath male and female flowers on the ſame plant; the male flowers have a partial involucrum, compoſed of four oval ſmall leaves, which incloſe three flowers; each of theſe has a proper bell-ſhaped empalement of one leaf; the petal is funnel-ſhaped, cut into ſix ſegments at the brim; it hath three ſhort ſtamina inſerted in the empalement, terminated by erect ſummits. The female flowers are

are ſhaped like the male, but want ſtamina; they have a roundiſh germen, ſupporting three ſlender ſtyles, crowned by acute ſtigmas. The empalement afterward becomes a large, ſwollen, oblong fruit, perforated at each end, incloſing one hard globular nut.

This genus of plants is ranged in the third ſection of Linnæus's twenty-firſt claſs, intitled Monœcia Triandria, which includes thoſe plants which have male and female flowers in the ſame plant, whoſe male flowers have three ſtamina.

We have but one Species of this genus in England, viz.

Hernandia (*Sonora*) foliis peltatis. Hort. Cliff. 485. tab. 13. Hernandia amplo hederæ folio umbilicato. Plum. *Hernandia with a large umbilicated Ivy leaf, commonly called in the Weſt-Indies, Jack-in-a-box.*

This plant is very common in Jamaica, Barbadoes, St. Chriſtopher's, and many other iſlands in the Weſt-Indies, where it is known by the name of Jack-in-a-box. The fruit of this plant when ripe, is perforated, and the nut in the inſide becomes hard; ſo that when the wind blows through the fruit, it makes a whiſtling noiſe, which may be heard at a diſtance; from whence, I ſuppoſe, the inhabitants gave this name to the plant. It grows in the gullies, where there are rills of water.

In Europe this plant is preſerved in curious gardens, with other tender exotic plants. It is propagated by ſowing the ſeeds in a hot-bed in the ſpring; and when the plants have ariſen two inches high, they ſhould be tranſplanted each into a ſeparate pot, filled with freſh rich earth, and plunged into the hot-bed again, obſerving to water and ſhade them until they have taken root; after which time they muſt have air admitted to them, (by raiſing the glaſſes) in proportion to the warmth of the air, or the heat of the bed in which they are placed; and ſhould be frequently watered, otherwiſe they will not thrive. As the plants advance, they ſhould be removed into larger pots, which ſhould be filled with rich earth; but in doing this, you ſhould be very careful not to break the roots, as alſo to preſerve a good ball of earth to them; and if their leaves ſhould hang after being removed, the plants muſt be ſcreened from the ſun until they have taken new root. The beſt time to ſhift theſe plants is in July, that they may be well rooted before the cold approaches; the plants muſt be conſtantly kept in the bark-ſtove: in winter they ſhould have a moderate ſhare of heat, and in the ſummer they muſt have plenty of air in hot weather. With this management, the plants will grow to the height of ſixteen feet or more, and the leaves being very large, will make a beautiful appearance in the ſtove. It hath not as yet flowered in England, though we may expect ſome of the large plants to flower in a ſhort time.

HERNIARIA. Tourn. Inſt. R. H. 507. tab. 228. Lin. Gen. Plant. 272. [of *Hernia*, Lat. a rupture.] Rupturewort.

The Characters are,

The flower hath no petals, but a coloured empalement of one leaf, cut into five parts which ſpread open. It hath five ſmall awl-ſhaped ſtamina, ſituated in the diviſions of the empalement, terminated by ſingle ſummits, and five others which are barren, placed alternately between them. In the center is an oval germen with two ſtigmas, which have acute points; the germen afterward turns to a ſmall capſule incloſed in the empalement, having one oval-pointed ſeed.

This genus of plants is ranged in the ſecond ſection of Linnæus's fifth claſs, intitled Pentandria Digynia, which includes the plants whoſe flowers have five ſtamina and two ſtyles.

The Species are,

1. **Herniaria** (*Glabra*) glabra herbacea. J. B. 3. 378. *Smooth Rupturewort.*
2. **Herniaria** (*Hirſuta*) hirſuta herbacea. J. B. 3. 379. *Rough or hairy Rupturewort.*
3. **Herniaria** (*Alſines folia*) alſines folio. Tourn. Inſt. 507. *Rupturewort with a Chickweed leaf.*
4. **Herniaria** (*Fruticoſa*) caulibus fruticoſis, floribus quadrifidis. Amœn. Acad. 4. p. 369. *Rupturewort with ligneous ſtalks and quadrifid flowers.* Herniaria fruticoſa, viticulis lignoſis. C. B. P. 382.

The two firſt ſorts grow naturally in England, but not very common; they are low trailing plants, their branches lying on the ground, and extend ſeven or eight inches each way; they have leaves like the ſmaller Chickweed, the firſt is ſmooth, and thoſe of the ſecond are hairy; the flowers come out in cluſters from the ſide of the ſtalks at the joints; they are ſmall, and of a yellowiſh green, ſo make no appearance.

The fourth ſort hath ſhrubby ſtalks which trail upon the ground, garniſhed with ſmall hairy leaves like the ſecond ſort; the flowers are alſo very like that.

The third ſort is an annual plant, which grows naturally in France and Italy. This doth not ſpread ſo much as either of the other ſorts, but the flowers and leaves are ſomewhat like the firſt, but larger.

Theſe plants are ſeldom cultivated, but in botanic gardens for the ſake of variety. The three firſt are annual plants, ſeldom continuing longer than one year; and muſt be permitted to ſhed their ſeeds, whereby they are better preſerved than if ſown with art. The fourth ſort is an abiding plant, which may be propagated by cuttings; but as they are plants of no beauty, they are rarely preſerved in gardens.

The firſt ſort is what ſhould be uſed in the ſhops, but is rarely ſeen in London, the herb-women commonly bringing the Parſley Breakſtone to the markets, which is ſold inſtead of this plant.

HESPERIS. Tourn. Inſt. R. H. 222. tab. 108. Lin. Gen. Plant. 731. [ſome derive the name of this plant from Heſperia, Italy, from whence the people were anciently called Heſperides; but it is pretty plain, that the name was taken from Ἕσπερος, becauſe the flower commonly ſmells moſt in an evening; either of theſe may be admitted. It is called Viola Matronalis, becauſe it reſembles the Violet, and was at firſt cultivated by women.] Dame's Violet, Rocket, or Queen's Gilliflower; in French, *Juliane*, or *Juliene*.

The Characters are,

The flower is compoſed of four oblong petals in form of a croſs, whoſe baſe or tails are narrow, and are ſituated in a four-leaved empalement, which falls away. It hath ſix awl-ſhaped ſtamina, four of them as long as the tube of the flower, and two much ſhorter, terminated by narrow erect ſummits, reflexed at their points. It hath a honey-gland ſituated between the two ſhort ſtamina, and a four-cornered germen the length of the ſtamina, but no ſtyle, the oblong erect ſtigma ſitting on the germen; the ſtigma is divided into two parts, which join at their points. The germen afterward becomes a plain, long, compreſſed pod with two cells, divided by an intermediate partition, incloſing many oval compreſſed ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's fifteenth claſs, intitled Tetradynamia Siliquoſa, the flowers having four long and two ſhort ſtamina, and are ſucceeded by long pods.

The Species are,

1. **Hesperis** (*Matronalis*) caule ſimplici erecto, foliis ovato-lanceolatis denticulatis, petalis mucrone emarginatis. Lin. Sp. 927. *Dame's Violet with a ſingle erect ſtalk, oval, ſpear-ſhaped, indented leaves, and the petals of the flowers indented at the top.* Heſperis hortenſis, flore purpureo. C. B. P. 202. *Garden Rocket with a purple flower.*
2. **Hesperis** (*Alba*) caule ſimplici erecto, foliis lanceolatis ſerratis, petalis integris. *Dame's Violet with a ſingle upright ſtalk, ſpear-ſhaped ſawed leaves, and the petals of the flower entire.* Heſperis hortenſis flore candido. C. B. P. 202. *Garden Rocket with a white flower.*
3. **Hesperis** (*Inodora*) caule ſimplici erecto, foliis ſubhaſtatis dentatis petalis obtuſis. Lin. Sp. 727. *Dame's Violet with a ſingle upright ſtalk, halbert-ſhaped, indented, obtuſe leaves and petals.* Heſperis ſylveſtris inodora. C. B. P. 202. *Unſavoury wild Rocket.*

4. **Hesperis** (*Triſtis*) caule hiſpido ramoſo patente. Hort. Upſal. 187. *Dame's Violet with a prickly, branching, ſpreading ſtalk.* Heſperis montana, pallidia, odoratiſſima. C. B. P. 202. *Sweeteſt pale Mountain Rocket.*

5. **Hesperis** (*Siberica*) caule ſimplici, folis lanceolatis dentato-ſerratis, petalis obtuſiſſimis integris. Lin. Sp. 927. *Dame's Violet with a ſingle ſtalk, ſpear-ſhaped ſawed leaves, and blunt entire petals to the flower.*

6. **Hesperis** (*Exigua*) caule ramoſiſſimo diffuſo, foliis lineari-lanceolatis dentatis, ſiliquis apice truncatis. *Dame's Violet with a very branching diffuſed ſtalk, narrow, ſpear-ſhaped, indented leaves, and the points of the pods ſhaped like a truncheon.* Heſperis exigua lutea, folio dentato anguſto. Boerh. Ind. 146. *Rocket with a very ſmall yellow flower, and a narrow indented leaf.*

7. **Hesperis** (*Dentata*) foliis dentato-pinnatifidis, caule lævi. Lin. Sp. Plant. 664. *Dame's Violet with wing-pointed indented leaves, and a ſmooth ſtalk.* Heſperis flore albo minimo, ſiliquâ longâ, folio profundè dentato. Boerh. Ind. alt. 2. 20. *Rocket with a ſmall white flower, a long pod, and leaves deeply indented.*

8. **Hesperis** (*Africana*) caule ramoſiſſimo diffuſo, foliis petiolatis lanceolatis acute dentatis ſcabris ſiliquis ſeſſilibus. Lin. Sp. Plant. 928. *Dame's Violet with very branching diffuſed ſtalks, ſpear-ſhaped, rough, ſawed leaves, and pods ſitting cloſe to the ſtalks.* Heſperis Africana, hieracii folio hirſuto, flore minimo purpuraſcente. Niſſol. Act. *African Rocket with a hairy Hawkweed leaf, and a very ſmall purpliſh flower.*

9. **Hesperis** (*Verna*) caule erecto ramoſo, foliis cordatis amplexicaulibus ſerratis villoſis. Lin. Sp. Plant. 664. *Dame's Violet with an erect branching ſtalk, and hairy, ſawed, heart-ſhaped leaves embracing the ſtalk.* Turritis annua verna, purpuraſcente flore. Tourn. Inſt. 224. *Annual vernal Tower Muſtard, with a purpliſh flower.*

The firſt ſort grows naturally in Italy; this was formerly in greater plenty in the Engliſh gardens than at preſent, having been long neglected becauſe the flowers were ſingle, and made but little appearance; however, as the flowers have a very grateful ſcent, ſo the plant is worthy of a place in every good garden. This riſes with an upright ſtalk a foot and a half high, garniſhed with ſpear-ſhaped leaves which ſit cloſe to the ſtalk, and are ſlightly indented on their edges, ending in acute points: the flowers are produced in a looſe thyrſe on the top of the ſtalks; they are compoſed of four petals, which are roundiſh and indented at their points, of a deep purple colour, and ſmell very ſweet, eſpecially in the evening or in cloudy weather. It flowers in June, and the ſeeds ripen the latter end of Auguſt. It is a biennial plant, ſo that young plants ſhould be raiſed every year, to ſupply the place of thoſe which decay: if the ſeeds are permitted to ſcatter, the plants will come up without trouble in the ſpring; and if the ſeeds are ſown, the beſt ſeaſon for it is in the autumn; becauſe thoſe which are ſown in the ſpring often fail if the ſeaſon proves dry, or will remain a long time in the ground before they vegetate. This plant ſhould have a loamy undunged ſoil, in which it will thrive better than in rich land.

There is a variety of this with double flowers, in ſome of the gardens in France; but that which we have in England, is a variety of the third ſort with unſavoury flowers.

The ſecond ſort has been generally ſuppoſed only a variety of the firſt, differing in the colour of the flower, but is certainly a diſtinct ſpecies; the leaves of this are not ſo long, but much broader than thoſe of the firſt, and their borders are entire; the flowers are not quite ſo large, nor do they form ſo good ſpikes; they are white, and have not ſo fine a ſcent as the firſt. This is alſo a biennial plant, requiring the ſame treatment as the firſt.

The third ſort grows naturally in Hungary and Auſtria. This riſes with an upright ſtalk near two feet high, garniſhed with ſpear-ſhaped leaves, ending in acute points, and ſharply indented on their edges; they are of a dark green, and ſit cloſe to the ſtalks; the flowers grow in looſe ſpikes on the top of the ſtalks; in ſome they are white, in others purple, and ſometimes both colours ſtriped in the ſame flower; theſe have no odour, ſo are not deſerving of a place in gardens, but may be propagated in the ſame manner as the two former.

From this ſort, the double white and purple Rockets have been accidentally obtained, which are much eſteemed for the beauty of their flowers; and if they had the agreeable odour of the Garden Rocket, they would be ſome of the beſt furniture for the borders of the flower-garden, but they are without ſcent; however, for the beauty of their flowers, they are by ſome greatly eſteemed, therefore I ſhall here inſert the beſt method of propagating them yet known.

Theſe plants are naturally biennial, ſo the plants with ſingle flowers rarely ſurvive the ſecond year; nor will thoſe with double flowers continue much longer; ſo that unleſs young plants are annually raiſed to ſupply the place of the old ones, there will ſoon be a want of them, which is what few perſons are careful enough to obſerve; but thinking the roots to be perennial, truſt to their putting out offsets, or the plants remaining after they have flowered; and finding them decay, are apt to think their ſoil very improper for them, and are at a loſs to account for their decaying; whereas, when the plants have flowered, they have finiſhed their period, and ſeldom continue to flower a ſecond time from the ſame root; though in poor land, they will often put out a few weak offsets, which may flower again, but ſeldom ſo ſtrong as the principal roots; therefore thoſe who are deſirous to propagate theſe plants, ſhould do it in the following manner:

There ſhould be ſome ſtrong roots of each ſort kept apart for this purpoſe, which are not intended to flower; when theſe have ſhot up their flower-ſtalks about ſix inches high, they ſhould be cut cloſe to the bottom; each of theſe may be divided in the middle to make two cuttings, which ſhould be planted in a ſoft, gentle, loamy ſoil, to an eaſt expoſure, where they may have only the morning ſun; and theſe may be planted pretty near together, ſo as to be covered with hand or bell-glaſſes, which ſhould be put over them after the cuttings have been well watered, and cloſely ſhut down, drawing the earth round the rim of the glaſſes to exclude the air; then the glaſſes ſhould be ſhaded with mats every day when the ſun is hot; and if the cuttings are gently refreſhed with water once in ſeven or eight days, it will be ſufficient, for too much moiſture will cauſe them to rot: when theſe are watered, the glaſſes ſhould be cloſely ſhut down again as before; with this management the cuttings will put out roots in five or ſix weeks, and will begin to ſhoot above; then the glaſſes ſhould be gently raiſed on one ſide to admit the air to them, and ſo gradually harden them to the open air, to prevent their drawing up weak. When theſe have made good roots, they ſhould be carefully removed, and planted in an eaſt border at about eight or nine inches aſunder, obſerving to ſhade and water them till they have taken new root; after which they will require no other care, but to keep them clean from weeds till the autumn, when they may be tranſplanted into the borders of the pleaſure-garden, where they are deſigned to flower.

The roots which are thus cut down, will ſend up more ſtalks than before; and when theſe are of a proper height, they may be cut off and treated in the ſame way; ſo that if the roots are ſound, there may be two or three crops of theſe cuttings taken from them, and by ſo doing, the old roots may be continued much longer than if they are permitted to flower; and by this management, there may be always a ſupply of good plants for the flower-garden.

Theſe plants are very ſubject to canker and rot when they are planted in a light rich ſoil, but in poor ſtrong ground, I have ſeen them thrive and flower in the utmoſt perfection, where the ſtems of flowers have been as large, and the flowers as fair as the fineſt double

Stock-gilliflowers. Their ſeaſon of flowering is in the beginning of June, and I have frequently raiſed young plants from the ſtalks after the flowers have decayed, by cutting them in lengths, and planting them in the manner before directed; but theſe ſeldom make ſo good plants as the young cuttings, nor are they ſo certain to grow, therefore the other are to be preferred.

The fourth ſort grows naturally in Hungary. This is much cultivated in the gardens abroad, for the great fragrancy of its flowers, which in the evening is ſo ſtrong, as to perfume the air at a great diſtance, eſpecially where there are any number of the plants. The ladies in Germany are very fond of this plant, and during the ſeaſon of their flowering, have the pots placed in their apartments every evening, that they may enjoy the fragrancy of their flowers; for they have but little beauty, being ſmaller than thoſe of the Garden Rocket, and of a pale colour, but the ſcent of their flowers is much preferable to them; though in the day-time, if the weather is clear, they have very little odour; but when the ſun leaves them, their fragrancy is expanded to a great diſtance. To this ſpecies it is ſuppoſed, that the title of Dame's Violet was firſt applied.

This ſort is very rarely ſeen in the Engliſh gardens: I ſuppoſe it has been neglected, becauſe the flowers make no appearance. It is a biennial plant like the Garden Rocket, which is propagated by ſeeds in the ſame manner; but the plants are not quite ſo hardy, and are very ſubject to rot in winter, eſpecially on a moiſt ſoil, or in rich land, where they are apt to grow very rank, ſo are ſoon injured by wet and cold in the winter; therefore the plants of this ſort ſhould be planted in a dry poor ſoil, and a warm ſituation; and if ſome of them are planted in pots to be placed under a common frame in winter, where they may be ſheltered from hard rains and froſt, but enjoy the free air at all times when the weather is mild, it will be a ſure way to preſerve them.

The leaves of this ſort are much larger than thoſe of the Garden Rocket, and of a paler green; the ſtalks are cloſely ſet with briſtly hairs; the flowers grow in looſe panicles at the top of the ſtalk, and appear about the ſame time with the Garden Rocket.

The ſeeds of the fifth ſort were ſent me from Germany without any title, nor any account of the country from whence it came; but as it was ſent with the ſeeds of ſome Siberian plants, I ſuppoſe this came from the ſame country. This is a biennial plant, which riſes with a ſtrong branching ſtalk between two and three feet high, which is very hairy, garniſhed with oblong heart-ſhaped leaves, ending in acute points, ſitting cloſe to the ſtalk; they are four inches long, and one and a half broad at their baſe, gradually diminiſhing to the point, and are ſlightly ſawed on their edges; the upper part of the ſtalk divides into two or three branches, which are garniſhed with ſmall leaves of the ſame ſhape with thoſe below, and are terminated with looſe panicles of ſingle, large, purple flowers of great fragrancy. This ſort flowered the end of June 1757, but the great rains which fell in Auguſt, rotted the plants before the ſeeds were ripe.

The ſixth ſort grows naturally in the warm parts of Europe; this is annual; the ſtalks riſe about eight or nine inches high, branching out greatly on every ſide in a confuſed order; they are garniſhed with ſmall, narrow, indented leaves, and are terminated by cluſters of ſmall yellow flowers, which make no appearance.

The ſeventh ſort grows naturally in Sicily. This is an annual plant, which ſeldom riſes more than ſix inches high; the ſtalk branches toward the top into three or four ſmaller, which are terminated by ſmall white flowers; the leaves are two inches long and one broad, cut almoſt to the midrib on each ſide, ſo as to reſemble a winged leaf.

The eighth ſort grows naturally in Africa. This is an annual plant with a very branching ſtalk, which riſes about nine inches high, garniſhed with rough ſpear-ſhaped leaves ſawed on their edges, and terminated by looſe panicles of ſmall purple flowers, which appear in June and July; theſe are ſucceeded by long pods ſitting cloſe to the ſtalks, and are filled with ſmall ſeeds which ripen in September.

Theſe three ſorts are rarely cultivated, except in botanic gardens for the ſake of variety. If the ſeeds of theſe are permitted to ſcatter, the plants will come up without care, and only require to be kept clean from weeds; or they may be ſown either in the ſpring or the autumn where they are to ſtand, for they do not bear tranſplanting well.

The ninth ſort is an annual plant, which grows naturally in the ſouth of France. This ſends out ſeveral heart-ſhaped leaves from the root, which ſpread on the ground; they are ſawed and hairy: the ſtalk riſes nine inches high, branching toward the top, garniſhed with leaves of the ſame ſhape, which embrace the ſtalks with their baſe; the flowers are produced in looſe panicles at the end of the branches; they are of a lively purple colour, and thoſe plants which riſe in the autumn, flower early in the ſpring. If theſe ſeeds are ſown in the autumn, they ſucceed much better than in the ſpring.

HEUCHERA. Lin. Gen. Plant. 283. Sanicle.

The Characters are,

The flower is compoſed of five narrow petals, which are inſerted in the border of the one-leaved empalement. It hath five erect awl-ſhaped ſtamina, which are much longer than the empalement, terminated by roundiſh ſummits. It hath a roundiſh bifid germen, with two erect ſtyles the length of the ſtamina, crowned by obtuſe ſtigmas. The germen afterward turns to an oval-pointed capſule with two horns, which are reflexed, having two cells filled with very ſmall ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's fifth claſs, which includes thoſe plants whoſe flowers have five ſtamina and two ſtyles.

We have but one Species of this genus, viz.

Heuchera (*Americana*.) Hort. Cliff. 82. Mitella Americana, flore ſquallidè purpureo villoſo. Boerh. Ind. alt. *Mitella of America, with hairy flowers of a dirty purple colour.*

This plant grows naturally in Virginia, but is hardy enough to thrive in the open air in England. It hath a perennial root, which ſends out many heart-ſhaped oval leaves, which are indented into four or five lobes, and are crenated on their edges, of a lucid green, and ſmooth; from between theſe come out the foot-ſtalks of the flower, which are naked, and riſe a foot high, dividing at the top into a looſe panicle, ſuſtaining many ſmall hairy flowers, of an obſolete purple colour. This flowers in May, and the ſeeds ripen in Auguſt.

It is propagated by parting the roots in autumn, and ſhould be planted in a ſhady ſituation; there is little beauty in this plant, but it is preſerved in ſome gardens for the ſake of variety.

HIBISCUS. Lin. Gen. Plant. 756. Ketmia. Tourn. Inſt. R. H. 99. tab. 26. *Syrian Mallow.*

The Characters are,

The flower has a double empalement, which is permanent; the outer is compoſed of eight or ten narrow leaves, the inner is ſhaped like a cup, and is of one leaf, cut at the brim into five acute points. It hath five heart-ſhaped petals, which join at their baſe into one. It hath many ſtamina, which are joined to the ſtyle, in form of a column, within the tube of the flower, but expand toward the top, and are terminated by kidney-ſhaped ſummits. It has a round germen, with ſlender ſtyles longer than the ſtamina, crowned by roundiſh ſtigmas. The germen afterward turns to a capſule with five cells, opening in five parts, incloſing kidney-ſhaped ſeeds.

This genus of plants is ranged in the third ſection of Linnæus's ſixteenth claſs, which includes thoſe plants whoſe flowers have many ſtamina joined to the ſtyles in one body, forming a column.

The Species are,

1. Hibiscus (*Syriacus*) foliis cuneiformi-ovatis, ſupernè inciſo-dentatis, caule arboreo. Hort. Cliff. 350. *Hibiſcus*

cus with wedge-ſhaped oval leaves, whoſe upper parts are cut, indented, and a tree-like ſtalk. Ketmia Syrorum quibuſdam. C. B. P. 316. *The Syrian Ketmia, commonly called Althæa frutex.*

2. Hibiscus (*Sinenſis*) foliis cordato-quinquangularis obſoletè ſerratis, caule arboreo. Hort. Upſal. 205. *Hibiſcus with heart-ſhaped leaves, having five angles which are ſlightly ſawed, and a tree-like ſtalk.* Ketmia ſinenſis, fructu ſubrotundo. Tourn. Inſt. R. H. 100. *China Ketmia with a roundiſh fruit, commonly called China Roſe.*

3. Hibiscus (*Abelmoſchus*) foliis ſubpeltato-cordatis ſeptemangularibus, ſerratis hiſpidis. Hort. Cliff. 349. *Hibiſcus with heart-ſhaped target leaves, having ſeven angles which are ſawed, and ſet with prickly hairs.* Ketmia Americana hirſuta, flore flavo, & ſemine moſchato. Tourn. Inſt. R. H. 100. *Hairy American Ketmia with a yellow flower and muſky ſeed, commonly called Muſk.*

4. Hibiscus (*Manihot*) foliis palmato-digitatis ſeptempartitis. Hort. Cliff. 350. *Hibiſcus with fingered leaves, which are divided into ſeven parts.* Ketmia Americana, folio Papayæ, flore magno flaveſcente, fundo purpureo, fructu erecto pyramidali hexagono, ſemine rotundulo ſapore fatuo. Boerh. Ind. alt. 1. 272. *American Ketmia with a Papaw leaf, and a large yellow flower, having a purple bottom, a pyramidal, ſix-cornered, erect fruit, and round ſeeds of a flat taſte.*

5. Hibiscus (*Tomentoſus*) foliis cordatis angulatis ſerratis tomentoſis, caule arboreo. *Hibiſcus with angular, heart-ſhaped, ſawed, woolly leaves, and a tree-like ſtalk.* Malva arboreo, folio oblongo acuminato veluto dentato & leviter ſinuato, flore ex rubro flaveſcente. Sloan. Cat. 95. *Tree Mallow with oblong, acute-pointed, indented leaves, ſlightly ſinuated, and a reddiſh yellow flower.*

6. Hibiscus (*Tiliaceus*) foliis cordatis ſubrotundis indiviſis acuminatis crenatis, caule arboreo. Prod. Leyd. 532. *Hibiſcus with entire heart-ſhaped leaves, and a tree-like ſtalk.* Ketmia Indica tiliæ folio. Tourn. Inſt. R. H. 100. *Indian Ketmia with a Lime-tree leaf.*

7. Hibiscus (*Javanica*) foliis ovatis acuminatis ſerratis glabris, caule arboreo. Flor. Zeyl. 260. *Hibiſcus with oval-pointed, ſawed, ſmooth leaves, and a tree-like ſtalk.* Alcea Javanica arboreſcens, flore pleno rubicundo. Bryen. Cent. 121. tab. 56. *Tree Vervain Mallow of Java, with a double red flower, called in India Shoe-flower.*

8. Hibiscus (*Vitifolis*) foliis ſerratis inferioribus ovatis indiviſis, ſuperioribus quinquepartitis, caule aculeato. Prod. Leyd. 358. *Hibiſcus with ſawed leaves, the lower oval and undivided, the upper divided into five parts, and a prickly ſtalk.* Ketmia Indica vitis folio, magno flore. Tourn. Inſt. R. H. 100. *Indian Ketmia with a Vine leaf and large flower.*

9. Hibiscus (*Sabdariffa*) foliis ſerratis, inferioribus cordatis, mediis tripartitis, ſummis quinquepartitis, caule aculeato. *Hibiſcus with ſawed leaves, the lower ones being heart-ſhaped, the middle divided into three parts, the upper into five, and a prickly ſtalk.* Ketmia Ægyptiaca vitis folio, parvo flore. Tourn. Inſt. R. H. 100. *Egyptian Ketmia with a Vine leaf and a ſmall flower.*

10. Hibiscus (*Goſſypifolius*) foliis quinquelobatis ſerratis, caule glabro. *Hibiſcus with ſawed leaves divided into five lobes, and a ſmooth ſtalk.* Ketmia Indica, Goſſyppii folio, acetoſæ ſapore. Tourn. Inſt. R. H. 100. *Indian Ketmia with a Cotton leaf, and the taſte of Sorrel.*

11. Hibiscus (*Ficulneus*) foliis quinquefido-palmatis, caule aculeato. Hort. Cliff. 498. *Hibiſcus with hand-ſhaped five-pointed leaves, and a prickly ſtalk.* Ketmia Zeylanica, fici folio, perianthio oblongo integro. Hort. Elth. 190. tab. 157. *Ketmia of Ceylon with a Fig leaf, and an oblong entire perianthium.*

12. Hibiscus (*Surattenſis*) foliis quinquepartitis, lobis ovato-lanceolatis hirſutis crenatis, caule ſpinoſſimo. *Hibiſcus with leaves divided into five lobes, which are oval, ſpear-ſhaped, hairy, and crenated, and a very prickly ſtalk.* Ketmia Indica aculeata, foliis digitatis. Tourn. Inſt. 101. *Prickly Indian Ketmia with hand-ſhaped leaves.*

13. Hibiscus (*Cordifolius*) foliis cordatis hirſutis crenatis, floribus lateralibus, caule arboreo ramoſo. *Hibiſcus with heart-ſhaped, hairy, crenated leaves, flowers growing from the ſides of the branches, and a tree-like branching ſtalk.* Ketmia Americana fruteſcens foliis ſubrotundis crenatis hirſutis, flore luteo. Houſt. *Shrubby American Ketmia with roundiſh, hairy, crenated leaves, and a yellow flower.*

14. Hibiscus (*Bahamenſis*) foliis oblongo-cordatis glabris, denticulatis, ſubtus incanis, floribus ampliſſimis. *Hibiſcus with oblong, heart-ſhaped, ſmooth, indented leaves, hoary on their under ſide, and very large flowers.*

15. Hibiscus (*Ficifolius*) foliis quinquepartito pedatis, calycibus inferioribus latere rumpentibus. Lin. Sp. Plant. 696. *Hibiſeus with leaves like a hand, divided into five parts, and the lower empalement torn ſideways.* Ketmia Braſilienſis, folio ficûs, fructu pyramidato ſulcato. Tourn. Inſt. R. H. 100. *Ketmia of the Braſils with a Fig leaf, and a pyramidal furrowed fruit.*

16. Hibiscus (*Pentacarpos*) foliis inferioribus cordatis angulatis, ſuperioribus ſubhaſtatis, floribus ſubnutantibus, piſtillo cernuo. Lin. Sp. Plant. 697. *Hibiſcus with lower leaves heart-ſhaped and angular, the upper ones ſomewhat ſpear-ſhaped, nodding flowers, and a recurved piſtil.* Ketmia paluſtris minor, folio anguſto, flore parvo purpuraſcente, fructu depreſſo pentagona. Zannich. Venet. 155. tab. 91. *Smaller Marſh Ketmia with a narrow leaf, a ſmall purpliſh flower, and a five-cornered depreſſed fruit.*

17. Hibiscus (*Populneus*) foliis ovatis acuminatis ſerratis, caule ſimpliciſſimo, petiolis floriferis. Hort. Upſal. 205. *Hibiſcus with oval-pointed ſawed leaves, a ſingle ſtalk, and foot-ſtalks having flowers.* Ketmia Africana Populi folio. Tourn. Inſt. 100. *African Ketmia with a Poplar leaf.*

18. Hibiscus (*Paluſtris*) caule herbaceo ſimpliciſſimo, foliis ovatis ſubtrilobis, ſubtus tomentoſis, floribus axillaribus. Lin. Sp. Plant. 693. *Hibiſcus with a ſingle herbaceous ſtalk, oval leaves having three lobes, woolly on their under ſide.* Ketmia paluſtris flore purpureo. Tourn. Inſt. 100. *Marſh Ketmia with a purple flower.*

19. Hibiscus (*Trionum*) foliis tripartitis inciſis, calycibus inflatis. Hort. Upſal. 206. *Hibiſcus with tripartite cut leaves, and a ſwollen empalement.* Ketmia veſicaria vulgaris. Tourn. Inſt. *Common Bladder Ketmia, called Venice Mallow, or Flower of an hour.*

20. Hibiscus (*Africana*) foliis tripartitis dentatis, lobis anguſtioribus caule hirſuto calycibus inflatis. *Hibiſcus with tripartite indented leaves having narrower lobes, a hairy ſtalk, and ſwollen empalements.* Ketmia veſicaria Africana. Tourn. Inſt. 101. *African Bladder Ketmia.*

21. Hibiscus (*Hiſpidus*) foliis inferioribus trilobis, ſummis quinque partitis obtuſis crenatis calycibus inflatis, caule hiſpido. *Hibiſcus with under leaves having three lobes, the upper being cut into five obtuſe ſegments, which are crenated, ſwollen empalements, and a prickly ſtalk.*

22. Hibiscus (*Malvaviſcus*) foliis cordatis-crenatis, angulis lateralibus extimis parvis, caule arboreo. Hort. Cliff. 349. *Hibiſcus with heart-ſhaped crenated leaves, whoſe outward lateral angles are ſmall, and a tree-like ſtalk.* Malvaviſcus arboreſcens, flore miniato clauſo. Hort. Elth. 210. tab. 170. *Tree-like, viſcous, ſeeded Mallow, with a cloſed ſcarlet flower.*

The firſt ſort is commonly called Althæa frutex by the nurſery gardeners, who propagate the ſhrubs for ſale; of this there are four or five varieties, which differ in the colour of their flowers; the moſt common hath pale purple flowers with dark bottoms; another hath bright purple flowers with black bottoms, a third hath white flowers with purple bottoms; a fourth variegated flowers with dark bottoms; and a fifth pale yellow flowers with dark bottoms; but the laſt is very rare at preſent in the Engliſh gardens; there are alſo two with variegated leaves, which are by ſome much eſteemed.

This grows naturally in Syria, from whence it has been introduced to the gardens, and is one of the great ornaments of the autumn ſeaſon: it riſes with a ſhrubby ſtalk to the height of ſix or ſeven feet, ſending out many ligneous branches, covered with a ſmooth gray bark, garniſhed with oval ſpear-ſhaped leaves, whoſe upper parts are frequently divided into three lobes, which are ſawed; theſe are placed alternately on the branches, ſtanding on ſhort foot-ſtalks. The flowers come out from the wings of the ſtalks at every joint of the ſame year's ſhoot; they are large, and ſhaped like thoſe of the Mallow, having five large roundiſh petals, which join at their baſe, ſpreading open at the top in ſhape of an open bell: theſe appear in Auguſt, and if the ſeaſon is not too warm, there will be a ſucceſſion of flowers part of September; the early flowers are ſucceeded by ſhort capſules with five cells, filled with kidney-ſhaped ſeeds; but unleſs the ſeaſon proves warm, they will not ripen in this country.

It is propagated by ſeeds, which ſhould be ſown in pots filled with light earth the latter end of March; and if they are plunged into a gentle heat, it will greatly forward the growth of the ſeeds. When the plants are come up, they muſt be inured to the open air, and in May the pots may be plunged into the ground, in a border expoſed to the eaſt, where they may have the morning ſun: the reaſon of my adviſing the pots to be plunged into the ground, is to prevent the earth from drying ſo faſt as it would do when the pots ſtand on the ſurface, ſo that the plants will not require ſo much water in ſummer; theſe plants will require no other culture, but to keep them clean from weeds, and in very dry weather to refreſh them with water during the firſt ſummer, but in autumn it will be proper to remove the pots under a common frame to ſcreen them from the froſt; or where there is not ſuch conveniency, they may be plunged cloſe to a hedge, pale, or wall, to a good aſpect; and in ſevere froſt, they ſhould be covered with mats, Straw, or other light covering; for although theſe plants, when they have obtained ſtrength, will reſiſt the cold of our winters, yet the young plants, whoſe ſhoots are tender, are very often injured by the firſt froſt of autumn: ſo that if they are not ſcreened the firſt year, they are often killed to the ground. Toward the latter end of March will be a good time to tranſplant theſe plants, at which time a ſpot of light ground muſt be prepared to receive them, which ſhould be divided into beds four feet broad, with paths of two feet broad between; then the plants ſhould be ſhaken out of the pots with the earth about them, and ſeparated with care, for their roots are very tender, and apt to break with little force; theſe ſhould be planted at about nine inches aſunder in the beds; ſo that if four rows are planted in each bed, there will be ſix inches allowed between the outſide rows and the paths. The ground ſhould be gently cloſed about the roots to prevent the air penetrating to them; and if a little old tanners bark, or mulch, is laid over the ſurface of the beds, it will prevent the earth from drying, and be of great uſe to the plants; during the following ſummer they muſt be kept clean from weeds, and if the following winter prove ſevere, it will be prudent to cover the plants again in autumn, eſpecially if they ſhoot late in the ſeaſon, or the autumn proves cold and moiſt, for then the plants will be in great danger of having their tops killed: in theſe beds the plants may remain two years, by which time they will be fit to tranſplant where they are deſigned to remain; for if they are kept longer in the nurſery, they will not remove ſo well. The beſt time for tranſplanting theſe plants is the end of March, or the beginning of April, for they ſeldom begin to ſhoot till the end of April, or the beginning of May; they ſhould have a light ſoil, not too wet, for in ſtrong land their ſtems grow moſſy, and they never thrive after.

Theſe plants may alſo be propagated by cuttings, which, if planted the latter end of March, in pots filled with light earth, and plunged into a gentle heat, will take root; but the plants ſo raiſed, are not ſo good as the ſeedlings. The ſeveral varieties may be propagated by grafting upon each other, which is the common method of propagating the ſorts with ſtriped leaves.

The ſecond ſort grows naturally in India, from whence the French firſt carried the ſeeds to their ſettlements in the Weſt-Indies; and the inhabitants of the Britiſh colonies there have been ſupplied with the ſeeds from them, ſo have given it the title of Martinico Roſe: of this there are the double and ſingle flowering, which from the ſeeds of the double the ſingle is frequently produced, but the ſeeds of the ſingle ſeldom vary to the double. The flowers of theſe plants alter in their colour, for at their firſt opening they are white, then they change to a bluſh Roſe colour, and as they decay they turn to a purple. In the Weſt-Indies, all theſe alterations happen the ſame day, as I ſuppoſe the flowers in thoſe hot countries are not of longer duration: but in England, where the flowers laſt near a week in beauty, the changes are not ſo ſudden.

This plant has a ſoft ſpongy ſtem, which, by age, becomes ligneous and pithy. It riſes to the height of twelve or fourteen feet, ſending out branches on every ſide toward the top, which are hairy, garniſhed with heart-ſhaped leaves, cut into five acute angles on their borders, and are ſlightly ſawed on their edges, of a lucid green on their upper ſide, but pale below, ſtanding alternately upon pretty long foot-ſtalks. The flowers are produced from the wings of the ſtalk, like thoſe of the firſt ſort; the ſingle one is compoſed of five large petals, which ſpread open, and are firſt white, but afterward change in the manner before-mentioned; theſe are ſucceeded by ſhort, thick, blunt capſules, which are very hairy, having five cells, which contain many ſmall kidney-ſhaped ſeeds, having a fine plume of fibrous down adhering to them.

This ſort is propagated by ſeeds, which muſt be ſown upon a hot-bed in the ſpring, and when the plants are fit to remove, they ſhould be each planted in a ſeparate ſmall pot filled with kitchen-garden earth, and plunged into a moderate hot-bed, where they muſt be ſhaded till they have taken new root; then they muſt be treated as other plants from warm countries, but not too tenderly, for theſe require a large ſhare of air in warm weather, otherwiſe they will draw up very weak: theſe plants ſhould not be quite expoſed to the open air the firſt ſeaſon, and the firſt winter will require the warmth of a moderate ſtove; but as they get more ſtrength, they may be treated with leſs care, for they will bear the open air in ſummer, in a warm ſheltered ſituation, and will live through the winter in a very good green-houſe, provided they have not too much wet; but the plants thus hardily treated, will not make ſo great progreſs, nor flower ſo well as with a little additional warmth; and if they are too tenderly managed, they will draw up weak, ſo will be leſs likely to flower. This ſort uſually flowers in England in November, ſo that it keeps to the uſual time of flowering in its native country.

The third ſort grows naturally in the Weſt-Indies, where it is commonly known by the title of Muſk; the French cultivate great quantities of theſe plants in their American Iſlands, the ſeeds of which are annually ſent to France in great quantities, ſo that they certainly have ſome way of rendering it uſeful, as it ſeems to be a conſiderable branch of trade. This riſes with an herbaceous ſtalk about three or four feet high, ſending out two or three ſide branches, garniſhed with large leaves cut into ſix or ſeven angles, which are acute, and ſawed on their edges; theſe ſtand on long foot-ſtalks, and are placed alternately. The ſtalks and leaves of this are very hairy. The flowers come out from the wings of the ſtalk upon pretty long foot-ſtalks, which ſtand erect; they are large, of a ſulphur colour, with dark purple bottoms, and are ſucceeded by pyramidal five-cornered capſules, which open in five cells, filled with large kidney-ſhaped ſeeds of a very muſky odour.

This ſort ſeldom lives more than one year in England, but in its native country will laſt two years. It is propagated by ſeeds, which, if ſown on a good hot-bed in the ſpring, and the plants afterward planted in pots filled with light earth, and plunged into a freſh hot-bed, treating them afterward in the ſame way as the Amaranthus, they will flower in July, and their ſeeds will ripen in autumn.

The fourth ſort grows naturally in both the Indies; this riſes with an herbaceous ſmooth ſtalk three or four feet high, garniſhed with leaves which are divided into ſeven ſegments almoſt to the bottom; the middle ſegment being four inches long and half an inch broad, the upper lateral ſegments about three inches long and the ſame breadth; theſe are indented at their extremities, but the lower ſegments are not much more than an inch long, and have foot-ſtalks four inches long. The flowers are produced from the wings of the ſtalks toward the top, ſtanding on ſhort foot-ſtalks; they are compoſed of five large ſulphur-coloured petals, which, when open, ſpread five inches wide; they have a dark purple bottom, with a column of ſtamina and ſtyles riſing in the center, and are ſucceeded by large, pyramidal, five-cornered, erect ſeed-veſſels, opening in five cells, which are filled with pretty large kidney-ſhaped ſeeds, which have little ſmell or taſte.

It is propagated by ſeeds in the ſame manner as the former ſort, and if ſo managed, will produce flowers and perfect ſeeds the ſame ſeaſon; but the plants may be continued through the winter in a moderate warmth, though few perſons are at the trouble of preſerving the plants after they have ripened their ſeeds, becauſe the young plants make a better appearance.

The fifth ſort grows naturally in the Weſt-Indies, where it riſes with a woody ſtalk ſeven or eight feet high, ſending out many ſide branches toward the top, which are covered with a whitiſh bark, and garniſhed with angular heart-ſhaped leaves, which are woolly; they are about four inches long, and three broad toward their baſe, ending in acute points, and have ſeveral longitudinal veins. The flowers are produced from the wings of the ſtalk upon long foot-ſtalks; they are compoſed of five roundiſh petals, which are joined at their baſe, but ſpread open above, and are of a yellow colour, turning to a red as they decay; theſe are ſucceeded by large, obtuſe, five-cornered, hairy ſeed-veſſels, which open in five cells, filled with large kidney-ſhaped ſeeds.

This is propagated by ſeeds, which muſt be ſown upon a hot-bed in the ſpring, and the plants afterward treated in the ſame way as the two laſt mentioned, during the firſt ſummer, but in the autumn they muſt be plunged into the tan-bed in the ſtove, where they ſhould conſtantly remain, and be treated in the ſame way as other tender plants from the ſame country, giving them but little water in winter; the ſecond year the plants will flower, but they have not as yet perfected ſeeds in England.

The ſixth ſort grows naturally in both Indies; this riſes with a woody pithy ſtem eight or ten feet high, dividing into ſeveral branches toward the top, which are covered with a woolly down, and garniſhed with round heart-ſhaped leaves, ending in acute points; they are of a lucid green on their upper ſide, and hoary on their under, full of large veins, and are placed alternately on the ſtalks. The flowers are produced at the end of the branches in looſe ſpikes; they are of a whitiſh yellow colour, and are ſucceeded by ſhort acuminated capſules, opening in five cells, filled with large kidney-ſhaped ſeeds.

This ſort is propagated in the ſame way, and the plants require the ſame treatment as the fifth, and flower the ſecond year, provided they are brought forward, otherwiſe they will not flower before the third or fourth ſeaſon; but they will bear the open air in ſummer, in a warm ſituation, though they will not make great progreſs there.

The ſeventh ſort grows naturally on the coaſt of Malabar, from whence I received the plants; this riſes with a woody ſtalk twelve or fourteen feet high, dividing into many ſmall branches toward the top, which are garniſhed with oval ſawed leaves, ending in acute points; they are of a lucid green above, but are pale on their under ſide, and are placed without order. The flowers come out from the ſide of the branches, at the wings of the leaves, on pretty long foot-ſtalks; they are compoſed of many oblong roundiſh petals of a red colour, which expand like the Roſe, the flowers being as large when fully blown, as the common red Roſe, and as double. This is a perennial plant, which is propagated by cuttings; and the plants muſt conſtantly be kept in the ſtove, giving them a large ſhare of air in warm weather, and but little water in winter. There is a variety of this with white flowers, but I have not ſeen any of the plants in the Engliſh gardens; nor have I ſeen the ſingle flowering kind, for the inhabitants of India propagate that with double flowers by cuttings, which put out roots freely; this they do for the ſake of flowers, which the women of that country make uſe of to colour their hair and eye-brows black, which will not waſh off: the Engliſh there uſe it for blacking of their ſhoes, and from thence have titled it Shoe-flower.

The eighth ſort is an annual plant, which riſes with an upright ſtalk ſeven or eight feet high; the lower leaves are oval, ſerrated, and entire, but the upper leaves are divided almoſt to the foot-ſtalk, into five ſpear-ſhaped ſegments, like the fingers of a hand, ſtanding on very long foot-ſtalks, which have thorns at their baſe, and are ſharply ſawed on their edges. The flowers come out from the wings of the ſtalks; they are large, of a pale ſulphur colour, with a dark purple bottom, and are ſucceeded by oval, acuminated, prickly capſules, which open in five cells, filled with large kidney-ſhaped ſeeds.

This ſort is propagated by ſeeds, which muſt be ſown upon a hot-bed, and the plants treated in the ſame way as the third ſort; and when they are grown too tall to ſtand under the frames, they muſt be placed in the ſtove, where they will flower in Auguſt, and the ſeeds will ripen in autumn.

The ninth ſort is near of kin to the eighth, but the ſtalks do not grow ſo tall; the lower leaves are heart-ſhaped and entire, the middle leaves are divided into three, and the upper into five ſegments, almoſt to the foot-ſtalks; they are ſawed on their edges, and the ſtalk is prickly. The flowers come out from the wings of the ſtalks; they are of a very pale ſulphur colour, with dark bottoms, but not ſo large as thoſe of the laſt.

This is propagated by ſeeds in the ſame way as the eighth, and the plants require the ſame treatment. It flowers in July and Auguſt, and the ſeeds ripen in autumn.

The bark of both theſe plants is full of ſtrong fibres, which I have been informed the inhabitants of the Malabar coaſt prepare and make into a ſtrong cordage; and by what I have obſerved, it may be wrought into fine ſtrong thread of any ſize, if properly manufactured.

The tenth ſort grows naturally in the Weſt-Indies, where the inhabitants uſe the green pods to add an acid taſte to their viands: there are two varieties of this, one with a light green, and the other a deep red pod, which always maintain their difference; but as there is no other difference but that of the colour of their pods, they do not deſerve ſeparate titles. This riſes with an herbaceous ſtem about three feet high, ſending out ſeveral lateral branches, which are garniſhed with ſmooth leaves divided into five lobes. The flowers come out from the ſide of the branches; they are of a dirty white, with dark purple bottoms, and are ſucceeded by obtuſe ſeed-veſſels, divided into five cells, which are filled with kidney-ſhaped ſeeds.

This ſort is propagated in the ſame way as the third, and will flower and perfect ſeeds the ſame year, ſo is ſeldom preſerved longer in England.

The eleventh ſort is a native of Ceylon; this riſes with an herbaceous ſtalk, which is prickly, from two to three feet high, dividing upward into ſmall branches, which are garniſhed with hand-ſhaped leaves, divided into five ſegments. The flowers come out from the wings of the leaves; they are ſmall and white, with purple bottoms, and are ſucceeded by ſhort obtuſe capſules with five cells, filled with kidney-ſhaped ſeeds. The ſeeds of this ſort were ſent me by Dr. Breynius of Dantzick.

This plant is annual, ſo muſt be treated in the ſame way as the third.

The twelfth ſort is alſo annual with us; this riſes with an herbaceous ſtalk three feet high, cloſely ſet with prickly hairs, and divides into branches upward, garniſhed with hand-ſhaped leaves, divided into five lobes, which are ſpear-ſhaped, ending in acute points; they are hairy, and crenated on their edges, ſtanding upon very long foot-ſtalks; the flowers come out from the wings of the ſtalk, and are very like thoſe of the third; this plant requires the ſame culture as the third ſort. The ſeeds of this were ſent me by Dr. Juſſieu, from Paris.

The thirteenth ſort was diſcovered by the late Dr. Houſtoun in the iſland of Cuba, from whence he ſent me the ſeeds. This riſes with a woody ſtalk twelve or fourteen feet high, ſending out many lateral branches, garniſhed with hairy heart-ſhaped leaves, crenated on their edges; the flowers come out ſingle from the wings of the leaves; they are of a very bright yellow colour, but not ſo large as either of the former ſorts, and are ſucceeded by ſhort capſules ending in acute points, divided into five cells, which are filled with kidney-ſhaped ſeeds. This plant is tender, ſo requires the ſame treatment as the fifth, and other tender kinds, with which management it flowers and produces good ſeeds here.

The fourteenth ſort has a perennial root but an annual ſtalk. The ſeeds of this were ſent me from the Bahama Iſlands, which ſucceeded in the Chelſea garden, where the plants produced plenty of flowers, but did not ripen their ſeeds. This riſes with ſeveral ſtalks from the root, which grow four feet high, garniſhed with oblong, heart-ſhaped, ſmooth leaves, ending in acute points, of a light green on their upper ſide, but hoary on their under, and are ſlightly indented on their edges, ſtanding upon long foot-ſtalks; the flowers are produced at the top of the ſtalks; they are very large, and of a light purple colour with dark bottoms, and are ſucceeded by ſhort capſules divided into five cells, filled with kidney-ſhaped ſeeds.

This is propagated by ſeeds, which muſt be ſown on a moderate hot-bed in the ſpring, and when the plants are fit to remove, they ſhould be each planted in a ſeparate ſmall pot, and plunged into a hot-bed, treating them in the ſame way as the other tender ſorts, but allowing them a greater ſhare of air in warm weather; for theſe may be brought to ſtand in the open air in ſummer, but unleſs the ſeaſon is very warm they will not flower there; for thoſe which flowered in the Chelſea garden, were plunged into atan-bed whoſe heat was declining, under a deep frame, where they produced plenty of flowers, but they came too late to ripen ſeeds. The ſtalks decay in the autumn, but if the pots are ſheltered under a hot-bed frame and ſecured from froſt, they will continue ſeveral years, and put out new ſtalks in the ſpring.

The fifteenth ſort is very common in the Weſt-Indies, where the inhabitants cultivate it for the pods or ſeed-veſſels, which they gather green to put into their ſoups; theſe, having a ſoft viſcous juice, add a thickneſs to their ſoups, and renders them very palatable. It riſes with a ſoft herbaceous ſtalk, from three to five feet high, dividing upward into many branches, garniſhed with hand-ſhaped leaves, divided into five lobes; the flowers are produced from the wings of the ſtalk; they are of a pale ſulphur colour with dark purple bottoms, but are ſmaller than either of the other ſorts, and of very ſhort duration, opening in the morning with the riſing ſun, but are faded long before noon in warm weather. Theſe are ſucceeded by capſules of very different forms, in the different varieties; in ſome the capſules are not thicker than a man's finger, and five or ſix inches long; in others they are very thick, and not more than two or three inches long; in ſome plants they grow erect, in others they are rather inclined; and theſe varieties are conſtant, for I have many years cultivated theſe plants, and have not found them vary.

This ſort is propagated by ſeeds in the ſame way as the third, and the plants require the ſame treatment, for they are too tender to thrive in the open air in this country; I have often tranſplanted the plants into warm borders, after they have acquired proper ſtrength, and have ſometimes in very warm ſeaſons had them thrive for a ſhort time, but the firſt cold or bad weather their leaves have all dropped off; and then they have decayed gradually, ſo that they have but rarely flowered, and have never in the beſt ſeaſons perfected their ſeeds; therefore thoſe who are inclinable to cultivate theſe plants, muſt conſtantly ſhelter them in bad weather.

The ſixteenth ſort grows naturally near Venice, in moiſt land; this hath a perennial root, and an annual ſtalk, which riſes from three to four feet high; the lower leaves are angular and heart-ſhaped, but the upper are ſpear-ſhaped, and ſlightly indented on their edges; the flowers are produced from the wings of the leaves, upon long foot-ſtalks; they are ſmall, and of a purple colour with a dark bottom, and are ſucceeded by five-cornered compreſſed capſules, filled with kidney-ſhaped ſeeds.

This ſort is propagated by ſeeds, which muſt be ſown on a hot-bed, and the plants ſhould be treated in the ſame way as the fourteenth ſort, otherwiſe they will not flower; for although the roots will live in the full ground here, yet the ſummers are not warm enough to bring them to flower. I have ſome of the roots which have remained ſeven years, putting up many ſtalks, which riſe upward of three feet, and have the flower-buds formed on their tops; but theſe appear ſo late in the ſeaſon, that they ſeldom have opened.

The ſeventeenth ſort grows naturally in North America; this hath a perennial root and an annual ſtalk; the roots of this ſort will live in the full ground, but unleſs the ſummer is warm, the flowers ſeldom open. It riſes with ſingle ſtalks from the root, two feet high or more; the leaves are oval and ſawed, the flowers are large and purple.

The eighteenth ſort grows naturally in North America, in moiſt ground. This hath a perennial root, and an annual ſtalk like the former, which is herbaceous and never branches; the leaves are oval, with three lobes which are not deeply divided; they are of a bright green on their upper ſide, but woolly on their under; the flowers are produced from the wings of the ſtalk; they are large, and of a bright purple colour. This ſort, like the former, ſeldom flowers in the open air here, unleſs the ſummer proves very warm, but the roots will live in the full ground, if they are planted in a ſheltered ſituation. The only way to have theſe plants flower in this country, is to keep the roots in pots, and ſhelter them under a frame in winter, and in the ſpring plunge them into a gentle hot-bed, which will cauſe them to put out their ſtalks early; and when the ſtalks are ſo high as to reach the glaſſes, the pots may be removed into a glaſs-caſe; where, if they are duly ſupplied with water, and have plenty of air in hot weather, they will flower very well in July, and in warm ſeaſons will ripen their ſeeds.

The nineteenth ſort is an annual plant, which grows naturally in ſome parts of Italy, and has been long cultivated in the Engliſh gardens, by the title of Venice Malva. Gerard and Parkinſon title it Alcea Veneta, and Flos Hora, or Flower of an hour, from the ſhort duration of its flowers, which in hot weather continue but few hours open: however, there is a ſucceſſion of flowers which open daily for a conſiderable time, ſo that a few of theſe plants may be allowed a place in every curious garden.

It riſes with a branching ſtalk a foot and a half high, having many ſhort ſpines which are ſoft, and do not appear unleſs cloſely viewed: the leaves are divided into three lobes, which are deeply jagged almoſt to the midrib; theſe jags are oppoſite, and the ſegments are obtuſe; the flowers come out at the joints of the ſtalks upon pretty long foot-ſtalks, having a double empalement, the outer being compoſed of ten long narrow leaves, which join at their baſe; the inner is of one thin leaf, ſwollen like a bladder, cut into five acute ſegments at the top, having many longitudinal purple ribs, and is hairy; both theſe are permanent, and incloſe the capſule after the flower is paſt. The flower is compoſed of five obtuſe petals, which ſpread open at the top, the lower part forming an open bell-ſhaped flower; theſe have dark purple bottoms, but are of a pale ſulphur colour above, having the ſtamina and apices joined in a column in the center; after the flower is paſt, the germen turns to a blunt capſule opening in five cells, which are filled with ſmall kidney-ſhaped ſeeds. It flowers in June, July, and Auguſt, and the ſeeds ripen about a month after. This ſort is propagated by ſeeds, which ſhould be ſown where the plants are deſigned to remain, for they do not bear tranſplanting well; if the ſeeds are ſown in autumn, the plants will come up early in the ſpring, ſo will flower in the ſummer, and thoſe which are ſown early in the ſpring will ſucceed them; ſo that by ſowing them at three different ſeaſons, they may be continued in ſucceſſion till the froſt ſtops them. Theſe require no other culture but to keep them clean from weeds, and thin them where they are too cloſe; and if the ſeeds are permitted to ſcatter, the plants will come up full as well as when ſown, ſo that it will maintain its ſituation unleſs it is weeded out.

The twentieth ſort grows naturally at the Cape of Good Hope; this is alſo an annual plant which reſembles the former, but the ſtalks grow more erect, are of a purpliſh colour, and very hairy; the leaves are compoſed of three lobes, which are divided almoſt to the foot-ſtalk; theſe are narrow, the middle lobe ſtretching out more than twice the length of the two ſide lobes, and they are but ſlightly indented on their edges, whereas thoſe of the former are cut almoſt to the midrib; the flowers are larger, and their colour deeper, than thoſe of the other.

The ſeeds of the twenty-ſecond ſort were ſent me from the Cape of Good Hope, a few years paſt. This is alſo an annual plant, having at firſt ſight ſome reſemblance of the other ſorts before-mentioned; but it riſes with ſtrong hairy branching ſtalks, garniſhed with much broader leaves than either of the former, the lower being divided into three, and the upper into five obtuſe lobes, which are crenated on their edges; the flowers are large, but of a paler colour than thoſe of the other. This has maintained the difference ten years, ſo that there is no doubt of its being a diſtinct ſpecies.

All theſe are as hardy as the nineteenth ſort, ſo may be treated in the ſame way.

The twenty-third ſort grows naturally at Campeachy, from whence the late Dr. Houſtoun ſent me the ſeeds. This differs ſo eſſentially from the other ſpecies in its fructification, as to deſerve another title; for all the other have dry capſules with five cells, including many kidney-ſhaped ſeeds, but this hath a ſoft viſcous berry, with a hard ſhell incloſed, containing five roundiſh ſeeds: it riſes with a ſhrubby ſtalk ten or twelve feet high, dividing into many branches, which are garniſhed with ſmooth, heart-ſhaped, angular leaves, which are crenated on their edges; the flowers come out from the wings of the ſtalks ſingly, ſtanding on ſhort foot-ſtalks; they are compoſed of five oblong petals, which are twiſted together and never expand; they are of a fine ſcarlet, and are ſucceeded by roundiſh berries of a ſcarlet colour when ripe, incloſing a hard ſhell which opens in five cells, each containing a ſingle roundiſh ſeed.

This ſort is generally propagated here by cuttings, becauſe the ſeeds do not often ripen here; if the cuttings are planted in pots filled with light earth, and plunged into a gentle hot bed, keeping the air from them, they will ſoon take root, and ſhould be gradually inured to bear the open air. Theſe plants require a moderate ſtove to preſerve them through the winter; and if they are kept in warmth in ſummer, they will flower, and ſometimes ripen fruit, though they may be placed abroad in a ſheltered ſituation for two or three months in ſummer, but the plants ſo treated ſeldom flower ſo well.

HIERACIUM. Lin. Gen. Plant. 818. Tourn. Inſt. R. H. 469. tab. 267. [of Ἱέραξ, *Gr.* a hawk; ſo called, becauſe hawks as well as eagles, have a ſtrong and quick ſight; and it is reported, that if by reaſon of the heat of the air, a film grows over the eyes of this bird, then the parent let falls a drop of the juice of it in its eye, which takes it off; and that, in like manner, it is good to clear the human ſight.] Hawkweed.

The CHARACTERS are,

It hath a flower compoſed of many hermaphrodite florets, which are included in one common ſcaly empalement, whoſe ſcales are narrow, and very unequal in their length and poſition; the florets are equal and uniform; they have one petal which is ſhaped like a tongue, indented in five ſegments at the point, placed imbricatim over each other; theſe have each five ſhort hairy ſtamina, terminated by cylindrical ſummits. At the bottom of the petal is ſituated the germen, ſupporting a ſlender ſtyle, crowned by two recurved ſtigmas; the germen afterward becomes a ſhort four-cornered ſeed crowned with down, ſitting in the empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's nineteenth claſs, which includes the plants with a compound flower, compoſed only of fruitful florets.

There are a great number of ſpecies of this genus, many of which grow naturally as weeds in England, and the others are ſo in different countries, therefore I ſhall only ſelect thoſe wihch are the moſt beautiful, and beſt worth cultivating from the number, which to enumerate, would ſwell this work greatly beyond its bounds.

1. HIERACIUM (*Aurantiacum*) foliis integris caule ſubnudo ſimpliciſſimo piloſo corymbifero. Hort. Cliff. 388. *Hawkweed with entire leaves, and a ſingle, hairy, naked ſtalk, terminated by a corymbus of flowers.* Hieracium hortenſe, floribus atro purpuraſcentibus. C. B. P. 128. *Garden Hawkweed with dark purple flowers.*
2. HIERACIUM (*Cerinthoides*) foliis radicalibus obovatis denticulatis, caulinis oblongis ſemiamplexicaulibus. Prod. Leyd. 124. *Hawkweed with oval indented leaves at the root, thoſe on the ſtalks oblong, and half embracing them.* Hieracium Pyrenaicum folio cerinthes. Schol. Bot. *Pyrenian Hawkweed with a Honeywort leaf.*
3. HIERACIUM (*Blattaroides*) foliis lanceolatis amplexicaulibus dentatis, floribus ſolitariis, calycibus laxis. Hort. Cliff. 387. *Hawkweed with ſpear-ſhaped indented leaves embracing the ſtalks, flowers growing ſingly, and looſe empalements.* Hieracium Pyrenaicum, blattariæ folio minus hirſutum. Tourn. Inſt. 472. *Pyrenean Hawkweed with a Moth Mullein leaf, leſs hairy.*
4. HIERACIUM (*Amplexicaule*) foliis amplexicaulibus cordatis ſubdentatis, pedunculis unifloris hirſutis, caule ramoſo. Hort. Cliff. 387. *Hawkweed with heart-ſhaped, indented, hairy foot-ſtalks, leaves embracing the ſtalks bearing one flower, and a branching ſtalk.* Hieracium Pyrenaicum rotundifolium amplexicaule. Schol. Bot. *Pyrenean Hawkweed, with round leaves embracing the ſtalks.*
5. HIERACIUM (*Sabaudum*) caule erecto multifloro, foliis ovato-lanceolatis dentatis ſemiamplexicaulibus. Prod. Leyd. 124. *Hawkweed with an erect ſtalk bearing many flowers, and oval ſpear-ſhaped leaves half embracing the ſtalk.* Hieracium ſabaudum altiſſimum, foliis latis brevibus, crebrius naſcentibus. Mor. Hiſt. 3. p. 71.

6. Hieracium (*Umbellatum*) foliis linearibus ſubdentatis ſparſis, floribus ſubumbellatis. Flor. Lapp. 287. *Hawkweed with linear indented leaves placed thinly, and flowers almoſt in an umbel.* Hieracium fruticoſum, anguſtiſſimo incano folio. H. L. 316.

The firſt ſort grows naturally in Syria; this ſends out from the root many oblong oval leaves, which are entire and hairy; from between the leaves ariſe a ſingle ſtalk, little more than a foot high, covered with hairs; the flowers are produced in a corymbus at the top; they are of a dark red colour, compoſed of many florets, which are ſucceeded by oblong black ſeeds, crowned with a white down, which, when ripe, by the elaſticity of the down, is drawn out of the empalement, and by the firſt ſtrong gale of wind, are wafted to a conſiderable diſtance. The flowers appear the beginning of June, and the ſeeds ripen in about five or ſix weeks after, but there is frequently a ſucceſſion of flowers till the autumn.

It is propagated by ſeeds, which ſhould be ſown on an eaſt aſpected border in March; and when the plants come up, they muſt be kept clean from weeds, till they are ſtrong enough to remove, which will be by the beginning of June; then they ſhould be tranſplanted to a ſhady border of undunged ground, at ſix inches diſtance, obſerving to water them if the weather ſhould prove dry, till they have taken new root; after which, if they are kept clean from weeds, they will require no other culture: in the autumn they ſhould be tranſplanted where they are deſigned to remain; the following ſummer they will flower and produce ripe ſeeds, and the roots will continue ſome years, if they are not planted in a rich moiſt ſoil, which frequently occaſions their rotting in winter.

The ſecond ſort grows naturally on the Pyrenean mountains. It is a perennial plant, whoſe lower leaves are oval, indented, and of a grayiſh colour; thoſe on the ſtalks are ſmaller, but of the ſame ſhape and colour, and half embrace the ſtalks with their baſe; the ſtalks riſe a foot high, branching out in ſeveral diviſions, each being terminated by one yellow flower. This is propagated by ſeeds as the firſt ſort.

The third ſort grows on the Pyrenees; this hath a perennial root, which ſends up ſeveral erect ſtalks, garniſhed with ſpear-ſhaped leaves which are indented; the flowers are produced from the wings of the ſtalks, upon ſhort foot-ſtalks, each ſuſtaining one large yellow flower, having a looſe empalement; this flowers in June; it is propagated by parting of the roots in autumn, and will thrive in any ſituation.

The fourth ſort riſes with a branching ſtalk a foot and a half high, garniſhed with heart-ſhaped leaves which are indented at their baſe, where they embrace the ſtalks; each diviſion of the branches terminate in a hairy foot-ſtalk, ſuſtaining one large yellow flower, which appears in June, and the ſeeds ripen in the end of July. This is a perennial plant, which is propagated by ſeeds as the firſt ſort, and requires the ſame treatment.

The fifth ſort grows naturally in Savoy; the root of this is perennial, ſending up ſeveral erect ſtalks near two feet high, garniſhed with ſhort, ſpear-ſhaped, indented leaves, half embracing the ſtalk with their baſe; the flowers are pretty large, of a deep yellow colour, terminating the ſtalks; it flowers in July.

The ſixth ſort grows naturally in Holland; it is a perennial plant, riſing with three or four ſlender ſtalks, garniſhed with hoary linear leaves, and terminated by yellow flowers. This rarely produces ſeeds in England, ſo is propagated by parting of the roots in autumn: but the fifth may be propagated either in the ſame manner, or from ſeeds as the firſt ſort, as it produces plenty of ſeeds here.

HILLS have many uſes, of which I ſhall only mention three or four.

1ſt, They ſerve as ſcreens, to keep off the cold and nipping blaſts of the northern and eaſtern winds.

2dly, The long ridges and chains of lofty mountains, being generally found to run from eaſt to weſt, ſerve to ſtop the evagation of thoſe vapours toward the poles, without which they would all run from the hot countries, and leave them deſtitute of rain.

3dly, They condenſe thoſe vapours, like alembic heads into clouds; and ſo by a kind of external diſtillation, give origin to ſprings and rivers; and by amaſſing, cooling, and conſtipating them, turn them into rain, and by that means render the fervid regions of the torrid zone habitable.

4thly, They ſerve for the production of a great number of vegetables and minerals, which are not found in other places.

It hath been found by experience and calculation, that Hills, though they meaſure twice as much as the plain ground they ſtand upon, yet the produce of the one can be no more than the other; and therefore, in purchaſing land, the Hills ought not to be bought for more than their ſuperficial meaſure, i. e. to pay no more for two acres upon the ſide of a Hill, than for one upon the plain, if the ſoil be equally rich.

It is true, that thoſe lands that are hilly and mountainous, are very different as to their valuable contents, from what are found in flat and plain ground, whether they be planted, ſown, or built upon, as for example:

Suppoſe a Hill contains four equal ſides, which meet in a point at top; yet the contents of theſe four ſides can produce no more grain, or bear no more trees, than the plain ground on which the Hill ſtands, or than the baſe of it; and yet by the meaſure of the ſides, there may be double the number of acres, rods, and poles, which they meaſure on the baſe or ground-plot.

For as long as all plants preſerve their upright method of growing, hilly ground can bear no more plants in number than the plain at the baſe.

Again, as to buildings on a Hill, the two ſides of a Hill will bear no more than the ſame number of houſes that can ſtand in the line at the baſe.

And as to rails, or park pailing over a Hill, though the meaſure be near double over the Hill to the line at the bottom, yet both may be incloſed by the ſame number of pales of the ſame breadth.

HIPPOCASTANUM. See Esculus.

HIPPOCRATEA. Lin. Gen. Plant. 54. Coa. Plum. Nov. Gen. 8. tab. 35.

The Characters are,

It hath a large ſpreading empalement of one leaf, cut at the top into five ſegments; the flower hath five oval petals, which are indented at the points. It hath three awl-ſhaped ſtamina, terminated by broad ſummits, and an oval germen ſituated below the petal, with a ſtyle the length of the ſtamina, crowned by an obtuſe ſtigma. The germen afterward becomes a heart-ſhaped capſule winged at the top, incloſing five ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's third claſs, intitled Triandria Monogynia, the flowers having three ſtamina and one ſtyle.

We have but one Species of this genus, viz.

Hippocratea (*Volubilis.*) Lin. Sp. 50. Plum. Gen. 8. *Hippocratea with a triple roundiſh fruit and a twining ſtalk.* Coa ſcandens, fructu trigemino ſubrotundo. Plum. Nov. Gen. 8. *Climbing Coa with a triple roundiſh fruit.*

The ſeeds of this plant were ſent me from Campeachy by Mr. Robert Millar, and ſeveral of the plants were raiſed in England, which continued two years in ſeveral gardens, but not one of them lived to flower; they grew to the height of eight or ten feet, twining round ſtakes, but their ſtalks were very ſlender, and decayed at the bottom, probably from their having too much wet.

It is a very tender plant, ſo muſt be conſtantly kept in the bark-bed in the ſtove, and ſhould have but little wet in winter.

HIPPOCREPIS. Lin. Gen. Plant. 791. Ferrum equinum. Tourn. Inſt. 400. tab. 225. Horſeſhoe Vetch; in French, *Fer de Cheval.*

The Characters are,

The empalement of the flower is permanent, of one leaf, divided into five parts, the two upper being joined. The flower is of the butterfly kind; the ſtandard hath a narrow baſe the length of the empalement, but is heart-ſhaped above; the wings are oval, oblong, and blunt; the keel is moon-ſhaped and compreſſed. It hath ten ſtamina, nine joined and one ſeparate, which ſtand erect, terminated by ſingle ſummits. It hath an oblong narrow germen, ſitting on an awl-ſhaped ſtyle, crowned by a ſingle ſtigma. The germen afterward becomes a long, plain, compreſſed pod, which is cut into many parts from the under ſeam to the upper, each part forming a roundiſh ſinus, with obtuſe three-cornered joints connected to the upper ſeam, each joint being ſhaped like a horſe-ſhoe, incloſing a ſingle ſeed.

This genus of plants is ranged in the third ſection of Linnæus's ſeventeenth claſs, intitled Diadelphia Decandria, which includes the plants with a leguminous flower, having ten ſtamina joined in two bodies.

The Species are,

1. Hippocrepis (*Uniſiliquoſa*) leguminibus ſeſſilibus ſolitariis. Hort. Cliff. 364. *Horſe-ſhoe Vetch with ſingle pods ſitting cloſe to the ſtalk.* Ferrum equinum, ſiliquâ ſingulari. C. B. P. 349. *Horſe-ſhoe Vetch with a ſingle pod.*
2. Hippocrepis (*Comoſa*) leguminibus pedunculatis confertis, margine exteriore repandis. Prod. Leyd. 384. *Horſe-ſhoe Vetch, with pods growing in cluſters upon foot-ſtalks, whoſe outer border is turned inward.* Ferrum equinum Germanicum, ſiliquis in ſummitate. C. B. P. 346. *German Horſe-ſhoe Vetch having pods on the tops of the ſtalks.*
3. Hippocrepis (*Multiſiliquoſa*) leguminibus pedunculatis confertis, margine altero lobatis. Hort. Cliff. 364. *Horſe-ſhoe Vetch with pods growing in cluſters upon foot-ſtalks, one border of which has lobes.* Ferrum equinum ſiliquâ multiplici. C. B. P. 346. *Horſe-ſhoe Vetch with many pods.*

The firſt ſort grows naturally in Italy and Spain. This is an annual plant, which ſends from the root ſeveral trailing ſtalks a foot long, that divide upward into ſmaller branches, garniſhed with winged leaves, compoſed of four or five pair of narrow ſmall lobes, terminated by an odd one, which are obtuſe, and indented at their ends; from the wings of the ſtalk come out ſingle flowers of the butterfly kind, which are yellow, and ſucceeded by ſingle pods ſitting cloſe to the ſtalks, which are about two inches long, and a third of an inch broad, bending inward like a ſickle, and divided into many joints ſhaped like a horſe-ſhoe. This flowers in June and July, and the ſeeds ripen in the autumn, ſoon after which the plants decay.

The ſecond ſort is found growing naturally in ſome parts of England, upon chalky hills, particularly at Hogmagog hills near Cambridge; this is a ſmaller plant than the former, and hath a perennial root, ſending out ſlender trailing ſtalks about ſix inches long, which are garniſhed with narrow winged leaves; the flowers grow in cluſters on the top of long foot-ſtalks; theſe are ſucceeded by pods which are ſhorter, and twiſted inward in roundiſh curves, but have joints ſhaped like thoſe of the former ſort.

The third ſort grows naturally in the ſouth of France, Germany, and Italy. This is an annual plant, with trailing ſtalks greatly reſembling the firſt, but the flowers are produced in cluſters on the top of pretty long foot-ſtalks; they are ſhaped like thoſe of the other ſorts, and the pods are jointed in like manner, but the joints are fixed to the oppoſite border. Theſe plants flower in June and July, and the ſeeds ripen in Auguſt and September.

Theſe plants are propagated by ſeeds, which ſhould be ſown in the autumn, where the plants are deſigned to remain; and when the plants come up, they muſt be kept clean from weeds, and thinned where they are too cloſe, which is all the culture they require. The two annual ſorts will decay in the autumn after they have perfected their ſeeds, but the roots of the other will continue two or three years, provided they are not in too good ground.

HIPPOLAPATHUM. See Rumex.

HIPPOMANE. Lin. Gen. Plant. 1099. Mançanilla. Plum. Nov. Gen. 50. tab. 30. The Manchineel.

The Characters are,

It hath male and female flowers in the ſame ſpike; the male flowers come out in ſmall cluſters, from a ſmall cup-ſhaped empalement; theſe have no petals; from the center of each empalement ariſes a ſingle ſtyle, terminated by two bifid ſummits. The female flowers have no petal, but an oval germen wrapped up in a three-leaved empalement; they have no ſtyle, but are crowned by a tripartite bifid ſtigma. The germen afterward becomes a roundiſh fruit with a fleſhy cover, incloſing a rough hard ſhell with ſeveral cells, each incloſing one oblong ſeed.

This genus of plants is ranged in the ninth ſection of Linnæus's twenty-firſt claſs, which includes the plants with male and female flowers, which have but one ſtamina.

The Species are,

1. Hippomane (*Mançinella*) foliis ovatis ſerratis. Hort. Cliff. 484. *Hippomane with oval ſawed leaves.* Mançanella pyrie facie. Plum. Nov. Gen. 50. *Manchineel with the appearance of the Pear-tree.*
2. Hippomane (*Biglanduloſa*) foliis ovato-oblongis, baſi glanduloſis. Lin. Sp. Plant. 1431. *Hippomane with oval oblong leaves, which have glands at their baſe.* Mançanilla lauri foliis oblongis. Plum. Nov. Gen. 50. *Manchineel with oblong Bay leaves.*
3. Hippomane (*Spinoſa*) foliis ſubovatis dentato ſpinoſis. Lin. Gen. Plant. 1191. *Hippomane with oval leaves which have prickly indentures.* Mançanilla aqui-folii foliis. Plum. Nov. Gen. 50. *Manchineel with Holly leaves.*

The firſt ſort grows naturally in all the iſlands of the Weſt-Indies. This is a very large tree in its native ſoil, almoſt equalling the Oak in ſize; the wood is much eſteemed for making of cabinets, book-caſes, &c. being very durable, and taking a fine poliſh; it is alſo ſaid, that the worms will not eat it: but as the trees abound with a milky cauſtic juice, ſo before they are felled, they make fires round their trunks to burn out their juice, otherwiſe they who fell them, would be in danger of loſing their ſight, by the juice flying in their eyes; and wherever this falls on the ſkin, it will raiſe bliſters; and if it comes upon linen, it will immediately turn it black, and on being waſhed will come into holes: it is alſo dangerous working of the wood after it is ſawn out, for if any of the ſawduſt happens to get into the workmens eyes, it cauſes inflammations, and the loſs of ſight for ſome time; to prevent which, they generally cover their faces with fine lawn, during the time they are working the wood.

This tree hath a ſmooth browniſh bark; the trunk divides upward into many branches, which are garniſhed with oblong leaves about three inches long, and one inch and a half broad, ending in acute points; they are ſlightly ſawed on their edges, and are of a lucid green, ſtanding on ſhort foot-ſtalks. The flowers come out in ſhort ſpikes at the end of the branches, being of both ſexes in the ſame ſpike, but having no petals they make but little appearance; theſe are ſucceeded by fruit, about the ſize and of the ſame ſhape as the Golden Pippin, turning of a yellow colour when ripe, which has often tempted ſtrangers to eat of them to their coſt, for they inflame the mouth and throat to a great degree, cauſing violent pains in the throat and ſtomach, which is dangerous, unleſs remedies are timely applied.

The inhabitants of America believe it is dangerous to ſit or lie under theſe trees, and affirm, that the rain, or dew, which falls from the leaves, will raiſe bliſters; but it is very certain, that unleſs the leaves are broken, and the juice of them mix with the rain, it will do no injury.

The ſecond ſort grows naturally at Carthagena in New Spain, and the third at Campeachy, from which places the late Dr. Houſtoun ſent me their ſeeds. The ſecond ſort grows to as large a ſize as the firſt. The leaves of this are much longer than thoſe of the firſt, and have two ſmall glandules growing at their baſe; they are ſawed on their edges, and are of a lucid green.

The third ſort is of humbler growth, ſeldom riſing more than twenty feet high; the leaves of this greatly reſemble thoſe of the common Holly, and are ſet with ſharp prickles at the end of each indenture; they are of a lucid green, and continue all the year.

Theſe plants are preſerved in ſome of the curious gardens in Europe, where they can never be expected to riſe to any great height, for they are too tender to live in theſe northern countries, but in ſtoves; they riſe eaſily from ſeeds, provided they are good. The ſeeds muſt be ſown upon a good hot-bed, and when the plants come up, they ſhould be each planted in a ſmall ſeparate pot filled with light ſandy earth, and plunged into a good bed of tanners bark, treating them in the ſame way as other tender plants; but they muſt not have much wet, for theſe plants abound with an acrid milky juice, and it is certain that moſt plants which do, are ſoon killed by much moiſture: theſe plants muſt be removed into the ſtove, and plunged into the tan-bed in autumn, where they ſhould conſtantly remain, giving them very little water in winter; and in ſummer when the weather is warm, they ſhould have a good ſhare of air admitted to them, and once or twice a week refreſhed with water; by this management I have raiſed many of theſe plants to the height of five or ſix feet, which have, by their ſhining green leaves, made a pretty variety during the winter ſeaſon in the ſtove.

HIPPOPHAE. Lin. Gen. Plant. 980. Rhamnoides. Tourn. Cor. 52. tab. 481. Baſtard Rhamnus, or Sea Buckthorn.

The CHARACTERS are,

It is male and female in different plants; the male flowers have an empalement of one leaf, cut into two ſegments, which cloſe at their points; they have no petals, but have four ſhort ſtamina, terminated by oblong angular ſummits, which are equal to the empalement. The female flowers hvve no petals, but have a one-leaved empalement, which is oval, oblong, tubulous, and bifid at the brim; theſe have no ſtamina, but in the center is ſituated a ſmall roundiſh germen, with a ſhort ſtyle, crowned by an oblong thick ſtigma, twice the length of the empalement. The germen afterward turns to a globular berry with one cell, incloſing one roundiſh ſeed.

This genus of plants is ranged in the fourth ſection of Linnæus's twenty-firſt claſs, intitled Diœcia Tetrandria, in which are included thoſe plants which are male and female in diſtinct plants, and the male flowers have four ſtamina.

The SPECIES are,

1. HIPPOPHAE (*Rhamnoides*) foliis lanceolatis. Lin. Sp. Plant. 1023. *Hippophae with ſpear-ſhaped leaves.* Rhamnoides ſalicis folio. Tourn. Cor. 53. *Sea Buckthorn with a Willow leaf.*
2. HIPPOPHAE (*Canadenſis*) foliis ovatis. Lin. Sp. Plant. 1024. *Hippophae with oval leaves, called Canada Sea Buckthorn.*

The firſt ſort grows naturally on the ſea-banks in Lincolnſhire, and alſo on the ſand-banks between Sandwich and Deal, in Kent; there are two varieties of this, one with yellow, and the other with red fruit; but it is the firſt only which I have obſerved growing naturally in England; the other I ſaw growing on the ſand-banks in Holland.

Theſe riſe with ſhrubby ſtalks eight or ten feet high, ſending out many irregular branches, which have a brown bark ſilvered over, garniſhed with very narrow ſpear-ſhaped leaves, about two inches long, and a quarter of an inch broad in the middle, leſſening gradually to both ends, of a dark green on their upper ſide, but hoary on their under, having a prominent midrib; the two borders of the leaves are reflexed like the Roſemary; theſe are placed alternate on every ſide the branches, ſitting very cloſe. The flowers come out from the ſide of the younger branches, to which they ſit very cloſe; the male flowers growing in ſmall cluſters, but the female come out ſingly; theſe make but little appearance. They appear in July, and the berries on the female plants are ripe in autumn.

This ſort is eaſily propagated by ſuckers from the root, for the roots ſpread wide, and ſend up a great number of ſhoots, ſo as to form a thicket: if theſe are taken off in autumn, and tranſplanted into a nurſery, they will be fit to tranſplant after one year's growth, to the places where they are to remain: as there is little beauty in this plant, ſo one or two of them may be allowed a place in a plantation of ſhrubs for the ſake of variety.

The ſecond ſort grows naturally in North America; this hath much the appearance of the former ſort, but the leaves differ in their ſhape, theſe being much ſhorter and broader, and are not ſo white on their under ſide. This hath not as yet flowered in this country, but the plants ſeem equally hardy with the former, and may be eaſily propagated by ſuckers or layers.

HIPPOSELINUM. See SMYRNIUM.

HIRUNDINARIA. See ASCLEPIAS.

HOEING is neceſſary and beneficial to plants, for two things: 1ſt, For deſtroying of weeds; 2dly, Becauſe it diſpoſes the ground better to imbibe the night dews, keeps it in a conſtant freſhneſs, and adds a vigour to the plants and trees, whoſe fruit by that means, becomes better conditioned than otherwiſe it would be.

This operation is performed by the hand, with an inſtrument called a Hoe, which is well known to every gardener. There are ſeveral ſizes of theſe; the ſmalleſt, which is called an Onion Hoe, is not more than three inches broad, and is uſed for Hoeing of Onions; not only to cut up the young weeds, but alſo to thin the Onions, by cutting up all thoſe which are too cloſe. The next ſize is near four inches and a half broad, and is called a Carrot Hoe; this is uſed for Hoeing of Carrots, or any other crop which requires the ſame room as thoſe. The largeſt ſize is about ſeven inches broad, and is frequently called a Turnep Hoe, being uſed for Hoeing of Turneps; but this is generally uſed by the kitchen-gardeners, for Hoeing between all their crops which are planted out, or ſtand ſo far aſunder as to admit an inſtrument of this breadth to paſs between the plants. Beſide, theſe ſort of Hoes, which are contrived to draw toward the perſon who uſes them, there is another ſort of a different form, which is called a Dutch Hoe; this is made for the perſon who uſes it to puſh from him, ſo that he does not tread over the ground which is hoed. This is a very proper inſtrument for ſcuffling over the ground to deſtroy weeds, in ſuch places where the plants will admit of its being uſed, and a perſon will go over a much greater ſpace of ground in the ſame time with one of theſe inſtruments, than with the common Hoe; but this inſtrument is not ſo proper for Hoeing out crops, ſo as to leave the plants at a proper diſtance, nor will it penetrate the ground ſo far; therefore the other ſort of hoe is to be preferred to this, becauſe it ſtirs the ground and looſens the ſurface, whereby the dews penetrate the ground, and thereby promote the growth of the plants. Of late years there has alſo been another inſtrument introduced in the field culture, called the Horſe Hoe, which is a ſort of plough with the ſhear ſet more inclining to a horizontal poſition than the common plough; but as moſt of the farmers are at a loſs how to uſe this inſtrument, ſo it has been but little practiſed in this country as yet; nor is it likely to be brought into uſe, unleſs the garden farmers near London, who are undoubtedly the beſt huſbandmen in Europe, introduce it; for the common farmers can never be ſuppoſed to alter their old eſtabliſhed methods, till by neceſſity they are drove to it: a ſtrong inſtance we have of this kind, in the culture of Turneps, which for many years were ſown in moſt of the counties in England, but till within about ſixty years paſt, they were never hoed, except within twenty or thirty miles of London, where the gardeners who had been bred in the kitchen-gardens near London, every ſeaſon went out in particular gangs to the different parts of the neighbouring country, and each party engaged to hoe the Turneps in ſuch a particular diſtrict, at a certain price per acre; and from the ſucceſs of the farmers who firſt employed them, their neighbours were at length tempted to follow their example, ſo that it became neceſſary for ſome of their labourers to underſtand this work; and from that time it has prevailed ſo much, as that many of the diſtant counties have now engaged in this practice: and if the Horſe-hoeing huſbandry was but well eſtabliſhed among the farmers near London, there would be little doubt of its ſpreading into the diſtant counties; but there are great prejudices againſt it at preſent, moſt of them ariſing from the ignorance of the farmers in general, and others from the over-fondneſs of the author to his own ſchemes, which has in many particulars carried him into many known abſurdities; and theſe being well known to every practical farmer and gardener, are ſufficient arguments with them againſt making trial of the uſeful part of his ſcheme.

The utility of this method of huſbandry, is firſt, in proportioning the number of plants to the paſture, which the ground is ſuppoſed capable of nouriſhing properly. The ſecond is, by frequent ſtirring of the ſurface of the land, all weeds which rob the crop of its nouriſhment is deſtroyed, and the clods of earth are hereby divided and pulverized, ſo that the roots of the plants can more eaſily penetrate them, and ſearch their proper food; beſides, the dews and moiſture are eaſily imbibed in the looſe ground, whereby the plants receive a greater ſhare of nouriſhment.

There are few perſons who properly conſider of what conſequence the ſtirring and breaking of the ſurface of the ground is to all crops growing therein. I have frequently made trial of this, when the crop has been ſo bad as to be thought not worth ſtanding, which has been occaſioned by the great quantity of rain which has fallen, whereby the ſurface of the ground has been ſo cloſely bound, as that the plants could find no nouriſhment, but have changed their uſual verdure to a purple colour, and have made no progreſs; but upon Hoeing the ground and breaking the clods, the plants have put out new roots, and have flouriſhed exceedingly. From many repeated trials of this kind I can affirm, that if the Wheat in general was ſowed in rows, ſo as that the plough may be brought between them in the ſpring, to looſen the ground, which by the winter's rains may have been too cloſely bound, the crop would more than double what is the common produce.

But the author of this ſcheme was too ſanguine in his propoſals, firſt, by aſſerting, that in this method of huſbandry, the land would conſtantly produce the ſame ſort of crops without diminution; and ſecondly, it might be done without dreſſing or manuring the ground; and his fondneſs for his own ſcheme carried him ſo far in the proſecution of it, as at laſt to have much worſe crops than any of his neighbours; however, this ſhould not diſcourage others from the practice of it, though upon different principles: for although the land thus cultivated, will not nouriſh the ſame plant without manuring ſeveral years, yet by this method of huſbandry I can affirm, that all crops will be ſo much improved, as to doubly anſwer the difference of expence, and leſs than a ſixth part of the ſeed will be enough for the ſame ſpace of ground. The common ſwing plough will anſwer all intents of Horſe-hoeing.

HOLCUS. Lin. Gen. Plant. 1015. Milium. Tourn. Inſt. R. H. 514. tab. 298. Sorgum. Mich. Indian Millet, or Corn.

The CHARACTERS are,

It hath male and hermaphrodite flowers ſometimes on the ſame plant, at others on different plants. The male flowers are ſmall, and have a bivalve chaff; theſe valves are oval, ſpear-ſhaped, and twiſted, ending with an acute beard; they have a ſmall hairy corolla with three hairy ſtamina, terminated by oblong ſummits. The hermaphrodite flowers are ſingle, in a ſtiff bivalve chaff; the inner of theſe is ſlender, hairy, and leſs than the empalement; the outer valve terminates in a rigid beard, and is larger than the empalement; they have three hairy ſtamina, terminated by oblong ſummits, with a roundiſh germen, ſupporting two hairy ſtyles, crowned with plumoſe ſummits. The germen afterward becomes an oval ſingle ſeed wrapped up in the chaff.

This genus of plants is ranged in the firſt ſection of Linnæus's twenty-third claſs, intitled Polygamia Monœcia which includes thoſe plants which have male and hermaphrodite flowers in different parts of the ſame plant, whoſe flowers have ſeveral ſtamina.

The SPECIES are,

1. HOLCUS (*Sorgum*) glumis villoſis, ſeminibus ariſtatis. Hort. Upſal. 301. *Holcus with hairy chaff and bearded ſeeds.* Milium arundinaceum, ſubrotundo ſemine, Sorgo nominatum. C. B. P. 26. *Reed-like Millet, with a roundiſh ſeed, called Sorgum.*
2. HOLCUS (*Saccharatus*) glumis glabris, ſeminibus muticis. Lin. Sp. Plant. 1047. *Holcus with ſmooth huſks, and ſeeds without awns.* Milium Indicum, arundinaceo caule, granis flaveſcentibus. H. L. 425. *Indian Millet with a reedy ſtalk, and yellowiſh grains.*

There are ſeveral other of the graſſy tribe which belong to this genus, but as they are not cultivated for uſe, ſo I ſhall not enumerate them here.

The two ſorts here mentioned, grow naturally in India, where their grain is often uſed to feed poultry, and the ſeeds of theſe are frequently ſent to Europe for the ſame purpoſe; but the ſummers are ſeldom warm enough to ripen the ſeeds in the open air in England, but in Italy they are both cultivated. The ſtalks of theſe plants riſe five or ſix feet high, which are ſtrong reedy, and like thoſe of the Maiz, or Turkey Wheat, but ſmaller. The leaves are long and broad, having a deep furrow through the center, where the midrib is depreſſed on the upper ſurface, and is very prominent below. The leaves are two feet and a half long, and two inches broad in the middle, embracing the ſtalks with their baſe. The flowers come out in large panicles at the top of the ſtalks, reſembling, at firſt appearance, the male ſpikes of the Turkey Wheat; theſe are ſucceeded by large roundiſh ſeeds, which are wrapped round with the chaff. Theſe plants are propagated in a few gardens for the ſake of variety, but as they are late in ripening their grain here, ſo they are not worth cultivating for uſe. The ſeeds ſhould be ſown on a warm border, or upon a gentle hot-bed in March; and when the plants come up, they ſhould be thinned and planted at the diſtance of a foot aſunder in the rows, and the rows ſhould be three feet diſtance; the culture after this, is to keep the ground clean from weeds, and draw the earth up with a hoe to the ſtems of the plants; if the ſeaſon proves warm, their panicles will appear in July, and the grain will ripen in September, but in bad ſeaſons their grain will not ripen here.

HORDEUM. Lin. Gen. Plant. 94. Tourn. Inſt. R. H. 513. tab. 293. Barley; in French, *Orge.*

The CHARACTERS are,

It hath a partial involucrum of ſix narrow-pointed leaves, which contain three flowers. The petal of the flower opens with two valves; the under valve is angular, ſwelling, oval, and pointed, being longer than the empalement, ending in a long beard; the inner is ſmall and ſpear-ſhaped. The flower hath three hairy ſtamina ſhorter than the petal, terminated by oblong ſummits. It hath an oval turned germen, ſupporting two hairy reflexed ſtyles, crowned by the like ſtigmas. The germen afterward becomes an oblong bellied ſeed,

ſeed, pointed at both ends, having a longitudinal furrow, ſurrounded by the petal of the flower, which does not fall off.

This genus of plants is ranged in the ſecond ſection of Linnæus's third claſs, which includes the plants whoſe flowers have three ſtamina and two ſtyles.

The Species are,

1. Hordeum (*Vulgare*) floſculis omnibus hermaphroditis ariſtatis ordinibus duobus erectioribus. Lin. Sp. Plant. 84. *Barley with all the flowers hermaphrodite, and two orders of beards, which are erect.* Hordeum polyſticum vernum. C. B. P. 22. *Spring Barley with many rows of grain.*

2. Hordeum (*Zeocriton*) floſculis lateralibus maſculis muticis, ſeminibus angularibus imbricatis. Hort. Upſal. 23. *Barley with male flowers on the ſide, without awns, and angular ſeeds placed over each other.* Hordeum diſtichon. C. B. P. 22. *Common long-eared Barley.*

3. Hordeum (*Diſtichon*) floſculis lateralibus maſculis muticis, ſeminibus angularibus imbricatis. Hort. Upſal. 23. *Barley with male flowers on the ſide, without awns, and angular imbricated ſeeds.* Hordeum diſtichum, ſpicâ breviore & latiore, granis confertis. Raii Syn. 246. *Barley with ſhorter and broader ſpikes, commonly called Sprat, or Battledore Barley.*

4. Hordeum (*Hexaſtichon*) floſculis omnibus hermaphroditis ariſtatis, ſeminibus ſexfariàm æqualiter poſitis. Hort. Upſal. 23. *Barley with all the flowers hermaphrodite, bearded, and ſix rows of ſeeds equally ranged.* Hordeum hexaſticum pulchrum. J. B. 2. 429. *Winter, or Square Barley, Bear Barley, or Big.*

The firſt ſort is the common Spring Barley, which is principally cultivated in England; of this the farmers make two ſorts, viz. the common and rath-ripe Barley, which are the ſame: for the rath-ripe has only been an alteration, occaſioned by being long cultivated upon warm gravelly lands. The ſeeds of this, when ſown in cold or ſtrong land, will the firſt year ripen near a fortnight earlier than the ſeeds taken from ſtrong land; therefore the farmers in the vales, generally purchaſe their ſeed Barley from the warm land; for if ſaved in the vales two or three years, it will become full as late in ripening as the common Barley of their own product; and the farmers on the warm land are alſo obliged to procure their ſeed Barley from the ſtrong land, otherwiſe their grain would degenerate in bulk and fulneſs, which by thus changing is prevented. This ſort of Barley is eaſily diſtinguiſhed by the two orders of beards, or awns, which ſtand erect; the chaff is alſo thinner than that of the two laſt ſpecies, ſo is eſteemed better for malting.

The ſecond ſort is the long-eared Barley, which is cultivated in many parts of England, and is an exceeding good ſort; but ſome farmers object to this ſort, becauſe they ſay the ears being long and heavy, it is more apt to lodge; this hath the grains regularly ranged in a double row, lying over each other like tiles on a houſe, or the ſcales of fiſhes. The huſk, or chaff of this Barley is alſo very thin, ſo is much eſteemed for malting.

The third ſort is uſually called Sprat Barley; this hath ſhorter and broader ears than either of the other ſorts; the awns, or beards, are longer, and the grains are placed cloſer together, and the awns being long, the birds cannot ſo eaſily get out the grains; this ſeldom grows ſo tall as the other ſpecies, the ſtraw is ſhorter and coarſer, ſo not very good fodder for cattle.

The fourth ſort is rarely cultivated in the ſouthern parts of England, but in the northern counties, and in Scotland, is generally ſown, being much hardier than the other ſpecies, ſo will bear the cold; this hath its grains diſpoſed in ſix rows: the grain is large and plump, but it is not ſo good for malting, which is the reaſon for its not being cultivated in the ſouthern parts of England, where the other ſorts, which are much better for that purpoſe, do thrive well.

All theſe ſorts of Barley are ſown in the ſpring of the year, in a dry time; in ſome very dry light land, the Barley is ſown early in March; but, in ſtrong clayey ſoils, it is not ſown till April, and ſometimes not until the beginning of May; but when it is ſown late, if the ſeaſon doth not prove very favourable, it is very late in autumn before it is fit to mow, unleſs it be the rath-ripe ſort, which is often ripe in nine weeks from the time of ſowing.

Some people ſow Barley upon land where Wheat grew the former year; but when this is practiſed, the ground ſhould be ploughed the beginning of October in a dry time, laying it in ſmall ridges, that the froſt may mellow it the better, and this will improve the land greatly; and if this can be ploughed again in January, or the beginning of February, it will break and prepare the ground better; then in March the ground is ploughed again, and laid even where it is not very wet; but in ſtrong wet lands the ground ſhould be laid round, and the furrows made deep to receive the wet. When this is finiſhed, the common method is to ſow the Barley-ſeed with a broad caſt at two ſowings; the firſt being harrowed in once, the ſecond is harrowed until the ſeed is buried; the common allowance of ſeed is four buſhels to an acre. This is the quantity of grain uſually ſown by the farmers; but if they could be prevailed on to alter this practice, they would ſoon find their account in it; for if leſs than half that quantity is ſown, there will be a much greater produce, and the corn will be leſs liable to lodge, as I have many years experienced; for when corn or any other vegetable ſtands very cloſe, the ſtalks are drawn up weak, ſo are incapable to reſiſt the force of winds, or bear up under heavy rains; but when they are at a proper diſtance, their ſtalks will be more than twice the ſize of the other, ſo are ſeldom laid. I have frequently obſerved in fields where there has been a foot-path through the middle, that the corn which has ſtood thin on each ſide the path hath ſtood upright, when all the reſt on both ſides has been laid flat on the ground: and whoever will obſerve theſe roots of corn near the paths, will find them tiller out (i. e. have a greater number of ſtalks) to more than four times the quantity of the other parts of the field. I have ſeen experiments made by ſowing Barley in rows acroſs divers parts of the ſame field, and the grains ſowed thin in the rows, ſo that the roots were three or four inches aſunder in the rows, and the rows at a foot diſtance; the intermediate ſpaces of the ſame field were at the ſame time ſown broad caſt in the uſual way; the ſucceſs was this, the roots which ſtood thin in the rows tillered out from ten or twelve, to upward of thirty ſtalks on each root, the ſtalks were ſtronger, the ears longer, and the grains larger than any of thoſe ſown in the common way; and when thoſe parts of the field where the corn was ſown in the uſual way has been lodged, theſe parts ſown thin have ſupported their upright poſition againſt wind and rain, though the rows have been made not only lengthways, but croſs the lands, in ſeveral poſitions, ſo that there could be no alteration in regard to the goodneſs of the land, or the ſituation of the corn; therefore where ſuch experiments have been frequently made, and always attended with equal ſucceſs, there can be no room to doubt which of the two methods is more eligible; ſince if the crops were only ſuppoſed to be equal in both, the ſaving more than half the corn ſown is a very great advantage, and deſerves a national conſideration, as ſuch a ſaving, in ſcarce times, might be a very great benefit to the public.

I know the farmers in general are very apt to complain if their corn does not come up ſo thick as to cover the ground green in a ſhort time, like Graſs fields; but I have often obſerved, that from the badneſs of the ſeaſon it has come up thin, or by accident has been in part killed, their corn has been ſtronger, the ears longer, and the grain plumper, ſo that the produce has been much greater than in thoſe years when it has come up thick; for the natural growth of corn is to ſend out many ſtalks from a root, and not riſe ſo much in height; therefore it is entirely owing to the roots ſtanding too near each other, when the ſtalks are drawn up tall and weak. I have had eighty-ſix ſtalks upon one root of Barley, which were ſtrong, produced longer ears, and the grain was better filled than any which I ever ſaw grow in the common method of huſbandry, and the land upon which this grew was not very rich: but I have frequently obſerved on the ſides of hot-beds in the kitchen-gardens, where Barley-ſtraw has been uſed for covering the beds, that ſome of the grains left in the ears has dropped out and grown, the roots have produced from thirty to ſixty ſtalks each, and thoſe been three or four times larger than the ſtalks ever arrive at in the common way: but to this I know it will be objected, that although upon rich land in a garden, theſe roots of corn may probably have ſo many ſtalks, yet in poor land they will not have ſuch produce; therefore unleſs there is a greater quantity of ſeeds ſown, their crop will not be worth ſtanding, which is one of the greateſt fallacies that can be imagined; for to ſuppoſe that poor land can nouriſh more than twice the number of roots in the ſame ſpace as rich land, is ſuch an abſurdity, as one could hardly ſuppoſe any perſon of common underſtanding guilty of; and yet ſo it is, for the general practice is to allow a greater quantity of ſeed to poor land, than for richer ground; not conſidering that where the roots ſtand ſo cloſe, they will deprive each other of the nouriſhment, ſo ſtarve themſelves, which is always the caſe where the roots ſtand cloſe; which any perſon may at firſt ſight obſerve, in any part of the fields where the corn happens to ſcatter when they are ſowing it; or in places where, by harrowing, the ſeed is drawn in heaps, thoſe patches will ſtarve, and never grow to a third part of the ſize as the other parts of the ſame field; and yet common as this is, it is little noticed by farmers, otherwiſe they ſurely would not continue their old cuſtom of ſowing. I have made many experiments for ſeveral years in the pooreſt land, and have always found that all crops which are ſown or planted at a greater diſtance than uſual, have ſucceeded beſt; and I am convinced, if the farmers could be prevailed on to quit their prejudices, and make trial of this method of ſowing their corn thin, they would ſoon ſee the advantage of this huſbandry.

The noblemen and gentlemen in France are very buſy in ſetting examples of this huſbandry in moſt of their provinces, being convinced by many trials of its great utility; and it were to be wiſhed, the ſame was done in England.

When the Barley is ſown, the ground ſhould be rolled after the firſt ſhower of rain, to break the clods and lay the earth ſmooth, which will render it better to mow, and alſo cauſe the earth to lie cloſer to the roots of the corn, which will be of great ſervice to it in dry weather.

Where Barley is ſown upon new broken up land, the uſual method is, to plough up the land in March, and let it lie fallow until June, at which time it is ploughed again, and ſown with Turneps, which are eaten by ſheep in winter, by whoſe dung the land is greatly improved; and then in March following the ground is ploughed up again, and ſown with Barley as before.

There are many people who ſow Clover with their Barley, and ſome have ſown the Lucern with Barley; but neither of theſe methods is to be commended, for where there is a good crop of Barley, the Clover or Lucern muſt be ſo weak as not to pay for ſtanding; ſo that the better way is to ſow the Barley alone without any other crop among it, and then the land will be at liberty for any other crop, when the Barley is taken off the ground; but this practice of ſowing Clover, Rye-graſs, and other Graſs-ſeeds, with corn, has been ſo long and univerſally eſtabliſhed among farmers, that there is little hope of prevailing with thoſe people to alter a cuſtom which has been handed down to them from their predeceſſors, although there ſhould be many examples produced, to ſhew the abſurdity of this practice.

When the Barley has been up three weeks or a month, it will be a very good method to roll it over with a weighty roller, which will preſs the earth cloſe to the roots of the corn, and thereby prevent the ſun and air from penetrating the ground, which will be of ſingular ſervice in dry ſeaſons; and this rolling of it before it ſtalks, will cauſe it to till out into a greater number of ſtalks; ſo that if the plants ſhould be thin, this will cauſe them to ſpread ſo as to fill the ground, and likewiſe to ſtrengthen the ſtalks.

The time for cutting of Barley is, when the red colour of the ears is off, and the ſtraw turns yellow, and the ears begin to hang down: in the north of England they always reap their Barley, and make it up in ſheaves, as practiſed here for Wheat, by which method they do not loſe near ſo much corn, and it is alſo more handy to ſtack; but this method cannot ſo well be practiſed where there are many weeds amongſt the corn, which is too frequently the caſe in the rich lands near London, eſpecially in moiſt ſeaſons; therefore when this is the caſe, the Barley muſt lie on the ſwarth till all the weeds are dead; but as it is apt to ſprout in wet weather, it muſt be ſhook up, and turned every fair day after rain to prevent it. When it is carried in, it ſhould be thoroughly dry, otherwiſe if it be ſtacked wet, it will turn muſty; or if too green, it is ſubject to burn in the mow. The common produce of Barley, is two and a half, or three quarters on an acre, but I have ſometimes known ſix or ſeven quarters on an acre.

HORIZONTAL SHELTERS have, by ſome perſons, been greatly recommended to preſerve fruit-trees from blights; but with how little reaſon, or upon what ſlight experiments, every one who has ever made uſe of them will eaſily judge; eſpecially thoſe which are contrived by placing tiles in the wall at certain diſtances, nothing being more obvious, than that vegetables, when prevented from receiving the advantage of dews, rains, &c. thoſe kindly benefits of heaven, grow weak, languid, and at laſt entirely decay: and ſince, from vaſt numbers of experiments which have been lately made, we find that trees imbibe great quantities of nouriſhment through the pores of their leaves and branches, whereby they are rendered vigorous and healthy, even in ſuch ſeaſons, and upon ſuch ſoils, where one would think it impoſſible they ſhould receive much nouriſhment from the earth; to deprive them of this advantage, is no leſs than deſtroying them; though perhaps, if the trees are vigorous, it may not be effected ſuddenly; but there will be very viſible ſigns of decay on them daily, and a few years will put a period to their lives, as I have more than once obſerved, where ſuch walls were built.

The only ſort of theſe ſhelters which I have ever obſerved uſeful for fruit-trees, was made with two leaves of ſlit deal, joined over each other, and painted; this being fixed upon the top of the wall with pullies, to draw up and down at pleaſure, formed a ſort of penthouſe; which being let down in great rains, or cold nights, during the time that the trees were in flower, or the fruit was ſetting, proved ſerviceable; but then theſe ſhelters were removed away ſoon after the fruit was ſet, ſo that the trees might enjoy all the advantages of rain, dew, &c. in the ſummer, which is abſolutely neceſſary, if we would have healthy trees or good fruit.

HORMINUM. Tourn. Inſt. 178. tab. 82. Salvia. Lin. Gen. Plant. 36. Clary; in French, *Ormin.*

The CHARACTERS are,

The empalement of the flower is permanent, of one leaf, tubulous, and channelled, having two lips; the upper is broad, ending in three acute points; the under is ſhorter, ending in two points. The flower has one petal, divided into two lips; the upper is concave, compreſſed on the two ſides, and incurved with a ſlight indenture at the point, the lower is broader and more indented. It hath two ſhort ſtamina, ſituated in the tube of the flower, terminated by ſhort proſtrate ſummits, and two other which decay ſoon after the flowers open. In the bottom of the tube are four roundiſh germen, ſupporting a ſingle ſtyle crowned by a bifid ſtigma, ſituated in the upper lip of the petal. The germen afterward becomes four ſeeds, lodged in the empalement.

This genus of plants is ranged in the firſt ſection of Tournefort's fourth claſs, which includes the herbs with a lip flower of one leaf, whoſe upper lip is forked, or ſhaped like a helmet. Dr. Linnæus has joined this genus, and alſo the Sclarea of Tournefort to the Salvia, including them all in that genus;

but as there are many ſpecies of each genus, ſo it is better to keep them aſunder, whereby their old titles, by which they have always been known in the ſhops and market will be retained, though there is no very eſſential difference in their characters.

The Species are,

1. Horminum (*Verbenacea*) foliis ſinuatis ſerratis, corollis calyce anguſtioribus acutis. *Clary with ſinuated ſawed leaves, and the petal of the flower narrower than the cup.* Horminum ſylveſtre lavendulæ flore. C. B. P. 239. *Wild Clary with a Lavender flower.*
2. Horminum (*Lyrata*) foliis pinnato-ſinuatis rugoſis, calycibus corollâ longioribus. *Clary with wing-ſhaped ſinuated leaves, which are rough, and the empalements longer than the petal of the flower.* Horminum folio querno. Volk. *Oak-leaved Clary.*
3. Horminum (*Verticillatum*) verticillis ſubnudis, ſtylo corollarum labio inferiore incumbente. *Clary with heart-ſhaped, crenated, indented leaves, naked whorls, and the ſtyle lying under the lip of the petal.* Horminum ſylveſtre latifolium verticillatum. C. B. P. 283. *Broad-leaved wild Clary, with flowers growing in whorls.*
4. Horminum (*Napifolium*) foliis radicalibus pinnato-inciſis, caulinis cordatis crenatis, ſummis ſemiamplexicaulibus. *Clary, whoſe lower leaves are cut and winged, thoſe on the ſtalks heart-ſhaped and crenated, and thoſe on the top half embracing the ſtalks.* Horminum napi folio. Mor. Hort. R. Blæſſ. *Clary with a Navew leaf.*
5. Horminum (*Sativum*) foliis obtuſis crenatis, bracteis ſummis ſterilibus majoribus coloratis. *Clary with obtuſe crenated leaves, the bracteæ on the top of the ſtalks large, coloured, and barren.* Horminum comâ purpuro-violaceâ. J. B. 3. 309. *Clary with a purple Violet top.*

The firſt ſort grows naturally on ſandy and gravelly grounds, in many parts of England. This a perennial plant; the lower leaves grow upon pretty long foot-ſtalks, and are near four inches long and two broad; they are ſinuated on their borders, and bluntly crenated; their ſurface is rugged and wrinkled; the ſtalks are a foot long, ſquare, and inclining toward the ground; the leaves upon theſe are ſmaller, and crenated on their edges; the flowers grow in a whorled ſpike at the top of the ſtalk, generally with two ſhorter ſpikes, one on each ſide; the flowers are ſmall and blue; theſe are ſcarce ſo long as their empalements; they have but one petal, which is divided into two lips, the upper being a little longer than the under, and almoſt ſhuts over it; there are but two perfect ſtamina in each flower, and four germen at the bottom, ſupporting a ſingle ſtyle; the germen afterward become ſo many naked ſeeds, ſitting in the empalement. It flowers in June and July, and the ſeeds ripen in Auguſt and September. This ſort propagates itſelf in plenty, if the ſeeds are permitted to ſcatter, and requires no other culture but to keep the plants clean from weeds.

This is ſometimes called Oculus Chriſti, from the ſuppoſed virtues of its ſeeds in clearing of the ſight, which it does by its viſcous covering; for when any thing happens to fall into the eye, if one of the ſeeds is put in at one corner, and the eye-lid kept cloſe over it, moving the ſeed gently along the eye, whatever happens to be there will ſtick to the ſeed, and ſo be brought out. The virtues of this are ſuppoſed to be the ſame as the Garden Clary, but not quite ſo powerful.

The ſecond ſort grows naturally in the ſouth of France and Italy; the lower leaves are upward of four inches long, and not more than one broad, regularly ſinuated on both ſides, in form of a winged leaf; the ſtalks riſe about the ſame height with the former, but all the leaves upon the ſtalks are ſinuated in the ſame manner as the lower; the flowers are ſmaller than thoſe of the firſt, but grow in whorled ſpikes like them. This is a perennial plant, which is very hardy, and will propagate itſelf in plenty by the ſcattered ſeeds. It is ſeldom kept in gardens but for the ſake of variety.

The third ſort is a perennial plant, which grows naturally in Auſtria and Bohemia. This ſends out from the root a great number of heart-ſhaped leaves, which are ſawed on their edges and deeply veined, ſtanding upon pretty long foot-ſtalks which are hairy; the ſtalks ariſe from between theſe, which are ſquare, and grow two feet and a half high, which are garniſhed with two heart-ſhaped leaves at each joint, whoſe baſe ſits cloſe to the ſtalks, half embracing them; the ſtalks at the two or three upper joints, put out on each ſide a long foot-ſtalk; theſe, and alſo the principal ſtalk, are garniſhed with whorls of ſmall blue flowers, not much unlike thoſe of the common ſort, but larger; the ſpikes are more than a foot long, and toward the top the whorls are nearer together. It flowers in June, and the ſeeds ripen in Auguſt.

The fourth ſort grows naturally in the ſouth of France, and in Italy. This is alſo a perennial plant, which has ſome reſemblance of the third, but the lower leaves of this are cut at their baſe to the mid-rib, into one or two pair of ears or lobes, which are but ſmall, and are often at a diſtance from each other; the leaves are not ſawed, but are bluntly indented; the ſtalks of this are ſlenderer, and do not grow ſo tall as thoſe of the third, nor are the ſpikes of flowers ſo long. This flowers and ſeeds at the ſame time with the third.

Both ſorts may be eaſily propagated by ſeeds, which, if ſown in the ſpring on an open ſpot of ground, the plants will come up, and require no other care but to keep them clean from weeds, and allow them room to grow; for the plants ſhould not be nearer than two feet apart, for they grow very large, and will laſt ſeveral years.

The fifth ſort is an annual plant, which grows naturally in Spain; of this there are three varieties which are conſtant, one with purple tops, another with red tops, and a third with green tops. As they differ in nothing but the colour of their bracteæ on the top of the ſtalks, ſo I have not put them down as different ſpecies, though from more than thirty years cultivating them, I have not known them alter.

Theſe plants have obtuſe crenated leaves, ſhaped like thoſe of the common red Sage; the ſtalks are ſquare and grow erect, about a foot and a half high; their lower parts are garniſhed at each joint with two oppoſite leaves of the ſame ſhape, but gradually diminiſhing in ſize toward the top: the ſtalks are garniſhed upward with whorls of ſmall flowers, and are terminated by cluſters of ſmall leaves, which in one are red, in another blue, and a third green, which make a pretty appearance, and are preſerved in gardens for ornament. They flower in June and July, and their ſeeds ripen in the autumn.

The ſeeds of theſe are ſown in the ſpring, in the places where they are deſigned to remain, and require no other care but to keep them clean from weeds, and thin them where they come up too cloſe.

Garden Clary. See Sclarea.

HORNBEAM. See Carpinus.

HORSE CHESTNUT. See Esculus.

HORSE DUNG is of great uſe to make hot-beds for the raiſing all ſorts of early garden crops, as Cucumbers, Melons, Aſparagus, Sallading, &c. for which purpoſe no other ſort of Dung will do ſo well, this fermenting the ſtrongeſt; and, if mixed with long litter, and ſea-coal aſhes in a due proportion, will continue its heat much longer than any other ſort of Dung whatſoever; and afterwards when rotted, becomes an excellent manure for moſt ſorts of lands, more eſpecially for ſuch as are of a cold nature; and for ſtiff clayey lands, when mixed with ſea-coal aſhes, and the cleanſing of London ſtreets, it will cauſe the parts to ſeparate much ſooner than any other compoſt will do; ſo that where it can be obtained in plenty, I would always recommend the uſe of it for ſuch lands.

HOSE IN HOSE, a term uſed in gardening, to ſignify one tube or petal within another, as in the

Polyanthus, where there are in ſome varieties two petals.

HOT-BEDS are of general uſe in theſe northern parts of Europe, without which we could not enjoy ſo many of the products of warmer climes as we do now; nor could we have the tables furniſhed with the ſeveral products of the garden, during the winter and ſpring months, as they are at preſent in moſt parts of England, better than perhaps in any other country in Europe: for although we cannot boaſt of the clemency of our climate, yet England is better furniſhed with all ſorts of eſculent plants for the table, much earlier in the ſeaſon, and in greater quantities, than in the gardens of our neighbours, which is owing to our ſkill in Hot-beds.

The ordinary Hot-beds which are commonly uſed in the kitchen-gardens, are made with new horſe dung, in the following manner:

1ſt, There is a quantity of new horſe dung from the ſtable (in which there ſhould be part of the litter or ſtraw which is commonly uſed in the ſtable, but not in too great proportion to the dung,) the quantity of this mixture muſt be according to the length of the bed intended; which, if early in the year, ſhould not be leſs than one good load for each light; this dung ſhould be thrown up in a heap, mixing therewith a few ſea-coal aſhes, ſome leaves of trees, and tan, which will be of ſervice to continue the heat of the dung; it ſhould remain ſix or ſeven days in this heap; then it ſhould be turned over, and the parts well mixed together, and caſt into a heap again, where it may continue five or ſix days longer, by which time it will have acquired a due heat; then in ſome well ſheltered part of the garden, you muſt dig a trench in length and width, proportionable to the frames you intend it for; and if the ground be dry, about a foot deep; but if wet, not above ſix inches; then wheel the dung into the opening, obſerving to ſtir every part of it with a fork, and lay it exactly even and ſmooth thro' every part of the bed; as alſo to lay the bottom part of the heap (which is commonly free from litter) upon the ſurface of the bed; this will prevent the ſteam from riſing ſo plentifully as it would otherwiſe do. To prevent this, and the heat from riſing ſo violently as to burn the roots of whatever plants are put into the ground, it will be a very good way to ſpread a layer of neats dung all over the ſurface of the horſe dung, which will prevent the mould from burning: if the bed is intended for Cucumbers or Melons, the earth ſhould not be laid all over the bed at firſt, only a hill of earth ſhould be firſt laid in the middle of each light on which the plants ſhould be planted, and the remaining ſpace ſhould be filled up from time to time as the roots of the plants ſpread; but this is fully explained under thoſe two articles. But if the hot-bed is intended for other plants, then after the bed is well prepared, it ſhould be left two or three days for the ſteam to paſs off, before the earth is laid upon the dung.

In the making of theſe hot-beds, it muſt be carefully obſerved to ſettle the dung cloſe with a fork; and if it be full of long litter, it ſhould be equally trod down cloſe in every part, otherwiſe it will be ſubject to heat too violently, and conſequently the heat will be much ſooner ſpent, which is one of the greateſt dangers theſe ſort of beds may be liable to. During the firſt week or ten days after the bed is made, you ſhould cover the glaſſes but ſlightly in the night, and in the day time carefully raiſe them to let out the ſteam, which is ſubject to riſe very copiouſly while the dung is freſh; but as the heat abates, ſo the covering ſhould be increaſed; otherwiſe the plants in the beds will be ſtinted in their growth, if not entirely deſtroyed. In order to remedy this evil, if the bed be very cold, you muſt put a pretty good quantity of new hot dung round the ſides of it, which will add a freſh heat thereto, and cauſe it to continue a conſiderable time after; and as the ſpring advances, the ſun will ſupply the loſs of the dung's heat; but then it will be adviſeable to lay ſome mowings of Graſs round the ſides of the bed, eſpecially if the nights ſhould prove cold, as it often happens in May, which is many times, even at that ſeaſon, very hurtful to tender plants on Hot-beds.

But although the Hot-bed I have deſcribed is what the kitchen-gardeners commonly uſe, yet thoſe made with tanners bark are much preferable, eſpecially for all tender exotic plants or fruits, which require an even degree of warmth to be continued for ſeveral months, which is what cannot be effected by horſe dung only. The manner of making theſe beds is as follows:

There muſt be a trench dug in the earth about three feet deep, if the ground be dry; but if wet, it muſt not be above a foot or ſix inches deep at moſt, and muſt be raiſed in proportion above ground, ſo as to admit of the tan being laid three feet thick. The length muſt be proportioned to the frames intended to cover it, but ſhould never be leſs than eleven or twelve feet; but if it is twice that length it will be better, and the width not leſs than ſix, which is the leaſt ſize of theſe beds for to continue the heat. This trench ſhould be bricked up round the ſides to the above-mentioned height of three feet, paving the bottom with bricks to prevent the earth mixing with the tan, and ſhould be filled in the ſpring with freſh tanners bark (i. e. ſuch as the tanners have lately drawn out of their vats, after they have uſed it for tanning leather) which ſhould be laid in a round heap for a week or ten days before it is put into the trench, that the moiſture may the better drain out of it, which, if detained in too great a quantity, will prevent its fermentation; then put it into the trench, and gently beat it down equally with a dung-fork; but it muſt not be trodden, which would alſo prevent its heating, by ſettling it too cloſe; then you muſt put on the frame over the bed, covering it with the glaſſes, and in about ten days or a fortnight it will begin to heat; at which time you may plunge your pots of plants or ſeeds into it, obſerving not to tread down the bark in doing it.

A Bed thus prepared (if the bark be new and not ground too ſmall) will continue in a good temper of warmth for two or three months; and when you find the heat decline, if you ſtir up the bark again pretty deep, and mix a load or two of freſh bark amongſt the old, it will cauſe it to heat again, and preſerve its warmth two or three months longer. There are many people who lay ſome hot horſe dung in the bottom of the trench, under the bark, to cauſe it to heat; but this is what I would never practiſe, unleſs I wanted the bed ſooner than the bark would heat of itſelf, and then I would put but a ſmall quantity of dung at bottom, for that is ſubject to make it heat too violently, and will occaſion its loſing the heat ſooner than ordinary; and there will never be any danger of the bark's heating if it be new, and not put into the trench too wet, though it may ſometimes be a fortnight or more before it acquires a ſufficient warmth, but then the heat will be more equal and laſting.

The frames which cover theſe Beds ſhould be proportioned to the ſeveral plants they are deſigned to contain: for example, if they are to cover the Ananas or Pine-apple, the back part of the frame ſhould be three feet and a half high, and the lower part fifteen inches, which will be a ſufficient declivity to carry off the wet; and the back ſide will be high enough to contain the large fruiting plants, and the lower ſide will be ſufficient for the ſhorteſt plants; ſo that by placing them regularly according to their height, they will not only have an equal diſtance from the glaſſes, but alſo appear much handſomer to the ſight. And although many people make their frames deeper than what I have allotted, yet I am fully perſuaded, that where there is but height enough to contain the plants, without bruiſing their leaves, it is much better than to allow a larger ſpace; for the deeper the frame is made, the leſs will be the heat of the air incloſed therein, there being no artificial warmth but what the bark affords, which will not heat a large ſpace of air; and as the Pine-apple requires to be conſtantly kept very warm, in order to ripen the fruit well, ſo it will be found upon trial, that the depth I have allowed will anſwer that purpoſe better than a greater.

But if the Bed be intended for taller plants, then the frame muſt be made in depth proportionable thereto; but if it be for ſowing of ſeeds, the frame need not be above fourteen or ſixteen inches high at the back, and ſeven inches deep in the front, by which means the heat will be much greater; and this is commonly the proportion allowed to the frames uſually made uſe of in the kitchen-gardens. As to their length, that is generally according to the fancy of the owner; but they commonly contain three lights each, which is in the whole about eleven feet in length, though ſometimes they are made to contain four lights; but this is too great a length for the boxes, for the frames thus made are not ſo handy to remove, as when they are ſhorter, and are more ſubject to decay at their corners. Some indeed have them to contain but two lights, which is very handy for raiſing Cucumber and Melon plants while young; but this is too ſhort for a Bark-bed, as not allowing room for a proper quantity of bark to continue a warmth for any conſiderable time, as was before-mentioned; but for the other purpoſes, one or two ſuch frames are very convenient for common Dung-beds.

As to thoſe frames which are made very deep, it is much the better way to have them made to take aſunder at the four corners, ſo that they may be removed with eaſe; otherwiſe it will be very difficult to take the frame off, when there is occaſion to put in new bark, or take out the old. The manner of making theſe frames is generally known, or may be much better conceived by ſeeing them than can be expreſſed in writing, therefore I ſhall forbear ſaying any thing more on this head.

HOTTONIA. Boerh. Ind. alt. 1. p. 207. Lin. Gen. Plant. 203. Stratoites. Vaill. Act. Par. 1719. Water Violet.

The Characters are,

The flower is funnel-ſhaped; it has one petal, with a tube the length of the one-leaved empalement, but is cut above into five oblong oval ſegments, which ſpread open, and are indented at their extremity. It hath five ſhort awl-ſhaped ſtamina ſtanding on the tube of the petal, oppoſite to the cuts, terminated by oblong ſummits. In the center is ſituated a globular germen ending in a point, ſupporting a ſhort ſlender ſtyle crowned by a globular ſtigma, which afterward becomes a capſule of the ſame form, with one cell, filled with globular ſeeds, ſitting upon the empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, which includes the plants whoſe flowers have five ſtamina and one ſtyle.

We know but one Species of this genus, viz.

Hottonia (*Paluſtris.*) Boerh. Ind. alt. 1. p. 207. Water Violet. Millifolium aquaticum ſive viola aquatica caule nudo. C. B. P. 141. *Water Milfoil, or Water Violet, with a naked ſtalk.*

This plant grows naturally in ſtanding waters in many parts of England; the leaves which are for the moſt part immerſed in the winter, are finely winged and flat, like moſt of the ſea plants; theſe extend pretty wide, and at the bottom have long fibrous roots, which ſtrike into the mud; the flower-ſtalks riſe five or ſix inches above the water; they are naked, and toward the top have two or three whorls of purple flowers, terminated by a ſmall cluſter of the ſame. Theſe flowers have the appearance of thoſe of the Stock-gilliflower, ſo make a pretty appearance on the ſurface of the water. The flowers appear in June.

It may be propagated in deep ſtanding waters, by procuring its ſeeds, when they are ripe, from the places of their natural growth, which ſhould be immediately dropped into the water where they are deſigned to grow, and the ſpring following they will appear; and if they are not diſturbed, they will ſoon propagate themſelves in great plenty.

HUMIDITY is the quality commonly called moiſture, or the power of wetting others, which quality ſome liquors and fluids are endowed with; and it differs very much from fluidity, in that it depends altogether on the congruity of the component particles of any liquor to the pores or ſurfaces of ſuch particular bodies, as it is capable of adhering to.

Thus, quickſilver is not a moiſt liquor, in reſpect to our hands or clothes, and many other things it will not ſtick to; but it may be called a moiſt liquor, in reſpect to gold, lead, or tin, to the ſurfaces of which it will preſently adhere.

Nay, water itſelf, that wets almoſt every thing, and is the great ſtandard of Humidity, or moiſture, is not capable of wetting every thing; for it ſtands, and runs eaſily off in globular drops, on the leaves of Cabbages, and many other plants; and will not wet the feathers of ducks, ſwans, and other water fowl.

And it is very plain, that it is only the texture that may cauſe the fluid to be humid; becauſe neither quickſilver alone, nor biſmuth, will ſtick upon glaſs; yet being mixed together, they will form a maſs that will ſtick on it; as it is very well known in the foliating of looking-glaſſes, in which ſuch a compoſition is uſed.

HUMULUS. See Lupulus.

HURA. Lin. Gen. Plant. 965. Hura, or Sand-box-tree.

The Characters are,

It hath male and female flowers on the ſame plant. The male flowers have no petal, or ſcarce any empalement, but a column of ſtamina, which are joined at bottom to the ſtyle, forming a cylinder; theſe ſpread out at the top, and are terminated by ſingle ſummits lying over each other. The female flowers have a ſwelling empalement of one leaf, with one tubulous petal; the roundiſh germen is ſituated in the bottom of the empalement, ſupporting a long cylindrical ſtyle, crowned by a large funnel-ſhaped ſtigma, which is a plain convex, divided into twelve equal obtuſe parts. The germen afterward becomes an orbicular ligneous fruit, depreſſed at top and bottom, having twelve deep furrows, with ſo many cells, which open at the top with an elaſticity, each containing one round flat ſeed.

This genus of plants is ranged in the ninth ſection of Linnæus's twenty-firſt claſs, intitled Monœcia Monodelphia, which includes thoſe plants which have male and female flowers at ſeparate diſtances in the ſame plant, whoſe ſtamina are joined to the ſtyle, forming one body.

We know but one Species of this genus, viz.

Hura (*Crepitans.*) Hort. Cliff. 486. *Sand-box-tree.* Hura Americana, Abutili Indici folio. Hort. Amſt. 2. 131. tab. 66. *American Hura with the leaf of the Indian Abutilon, commonly called in the Weſt-Indies Sand-box-tree.*

This grows naturally in the Spaniſh Weſt-Indies, from whence it has been introduced into the Britiſh colonies of America, where ſome of the plants are preſerved by way of curioſity. It riſes with a ſoft ligneous ſtem to the height of twenty-four feet, dividing into many branches, which abound with a milky juice, and have ſcars on their bark, where the leaves have fallen off. The branches are garniſhed with heart-ſhaped leaves; thoſe which are the biggeſt are eleven inches long, and nine inches broad in the middle, indented on their edges, having a prominent midrib, with ſeveral tranſverſe veins from that to the ſides, which are alternate; theſe ſtand upon long ſlender foot-ſtalks. The male flowers come out from between the leaves, upon foot-ſtalks which are three inches long; they are formed into a cloſe ſpike, or katkin, forming a column, lying over each other like the ſcales of fiſh. The female flowers are ſituated at a diſtance from the male; theſe have a ſwelling cylindrical empalement, out of which riſes the petal of the flower, which hath a long funnel-ſhaped tube, ſpreading at the top, where it is divided into twelve parts, which are reflexed. After the flower is paſt, the germen ſwells and becomes a round, compreſſed, ligneous capſule, having twelve deep furrows, each being a diſtinct cell, containing one large round compreſſed ſeed; when the pods are ripe, they burſt with an elaſticity, and throw out their ſeeds to a conſiderable diſtance.

It is propagated by ſeeds, which ſhould be ſown early in the ſpring, in pots filled with light rich earth, and plunged into a hot-bed of tanners bark. If the ſeeds are freſh, the plants will appear in about five or ſix weeks after the ſeeds are ſown. As the plants will advance very faſt, where due care is taken of them, ſo they ſhould have a large ſhare of freſh air admitted to them in warm weather, otherwiſe they will draw up too weak. When the plants are about two inches high, they ſhould be tranſplanted each into a ſeparate ſmall pot filled with light rich earth, and plunged again into the hot-bed of tanners bark, being careful to ſhade them from the heat of the ſun, until they have taken new root; after which time they muſt have free air admitted to them, by raiſing of the glaſſes in proportion to the warmth of the ſeaſon, and ſhould be frequently, but gently, watered. When the plants have filled theſe ſmall pots with their roots, they muſt be ſhaken out of them, and their roots trimmed, and then placed in larger pots, which ſhould be filled with the like rich earth, and plunged again into the hot-bed, where they ſhould remain till Michaelmas, provided the plants have room, without touching of the glaſſes, at which time they muſt be removed into the bark-ſtove, and plunged in the warmeſt part thereof: during the winter ſeaſon they muſt be ſparingly watered, for as the plants have ſucculent ſtalks, much moiſture will rot them; they muſt alſo be kept very warm, otherwiſe they will not live in this country. In ſummer they muſt have a large ſhare of freſh air in warm weather, but they muſt not be removed into the open air, for they are too tender to live abroad in the warmeſt part of the year in this country.

This plant is now pretty common in the Engliſh gardens, where there are collections of tender plants preſerved, ſome of which are grown to the height of twelve or fourteen feet, and many of them have produced flowers, but there has not been any of their fruit produced as yet in England.

As theſe plants have ample leaves, which are of a beautiful green colour, they afford an agreeable variety among other tender exotic plants in the ſtove; for where they are kept warm, and duly refreſhed with water, they retain their leaves all the year in verdure.

The fruit of this plant is, by the inhabitants of the Weſt-Indies, cut open on the ſide where the foot-ſtalk grew, and the ſeeds carefully taken out, after which the ſhells are uſed to contain ſand for writing, which gave riſe to the name of Sand-box. When theſe fruit are brought entire into England, it is very difficult to preſerve them; for when the heat of the ſummer comes on, they uſually burſt with an exploſion, and ſcatter their ſeeds about; and from the noiſe made by the ripe fruit, it was by Hernandez titled, Arbor crepitans.

HYACINTHUS. Tourn. Inſt. R. H. 344. tab. 180. Lin. Gen. Plant. 427. Hyacinth; in French, *Jacinte*.

The CHARACTERS are,

The flower has no empalement. It has one bell-ſhaped petal, whoſe rim is cut into ſix parts, which are reflexed; and three nectariums on the point of the germen, with ſix ſhort awl-ſhaped ſtamina, terminated by ſummits, which cloſe together. In the center is ſituated a roundiſh three-cornered germen, having three furrows ſupporting a ſingle ſtyle, crowned by an obtuſe ſtigma. The germen afterward becomes a roundiſh three-cornered capſule, having three cells, which contain roundiſh ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's ſixth claſs, intitled Hexandria Monogynia, which includes thoſe plants whoſe flowers have ſix ſtamina and but one ſtyle.

The SPECIES are,

1. HYACINTHUS (*Nonſcriptas*) corollis campanulatis ſexpartitis apice revolutis. Hort. Cliff. 125. *Hyacinth with a bell-ſhaped petal divided into ſix parts, which are reflexed at their tops.* Hyacinthus oblongo flore cæruleus major. C. B. P. 43. *Greater Hyacinth with an oblong blue flower*; and the Hyacinthus Anglicus. Ger. 99. *Engliſh Hyacinth, or Hare Bells.*
2. HYACINTHUS (*Serotinus*) corollarum exterioribus petalis ſubdiſtinctis, interioribus coadunatis. Lin. Sp. Plant. 453. *Hyacinth whoſe exterior part of the flower has diſtinct petals, but the interior joined.* Hyacinthus obſoleto flore. C. B. P. 44. *Hyacinth with a worn-out flower.*
3. HYACINTHUS (*Utrinque Floribus*) corollis campanulatis ſexpartitis, floribus utrinque diſpoſitis. *Hyacinth with a bell-ſhaped petal which is divided into ſix parts, and flowers ranged on each ſide of the ſtalk.* Hyacinthus floribus campanulæ utrinque diſpoſitis. C. B. P. 44. *Hyacinth with bell-ſhaped flowers diſpoſed on every ſide the ſtalk.*
4. HYACINTHUS (*Cernuus*) corollis campanulatis ſexpartitis racemo cornuo. Lin. Sp. Plant. 217. *Hyacinth with bell-ſhaped petals divided into ſix parts, and a nodding branch of flowers.* Hyacinthus floribus campanulæ, uno verſu diſpoſitis. C. B. P. 44. *Hyacinth with bell-ſhaped flowers ranged on one ſide the ſtalk.*
5. HYACINTHUS (*Amethyſtinum*) corollis campanulatis ſemiſexfidis baſi cylindricis. Hort. Upſal. 58. *Hyacinth with bell-ſhaped petals cut half way into ſix parts, and a cylindrical baſe.* Hyacinthus oblongo cæruleo flore minor. C. B. P. 44. *Leſſer Hyacinth with an oblong blue flower.*
6. HYACINTHUS (*Orientalis*) corollis infundibuliformibus ſemiſexfidis baſi ventricoſis. Hort. Upſal. 85. *Hyacinth with a funnel-ſhaped petal cut half into ſix parts, and ſwelling at their baſe.* Hyacinthus Orientalis albus primus. C. B. P. 44. *Early White Eaſtern Hyacinth.*

The ſorts here mentioned are all of them diſtinct ſpecies, of which there are ſeveral varieties, eſpecially of the ſixth, which have been cultivated with ſo much art, as to render ſome of them the moſt valuable flowers of the ſpring; in Holland the gardens abound with them, where the floriſts have raiſed ſo many varieties as to amount to ſome hundreds; and ſome of their flowers are ſo large, double, and finely coloured, as that their roots are valued at twenty or thirty pounds ſterling each root; to enumerate theſe varieties here, would ſwell this work to very little purpoſe, as every year produces new kinds.

The firſt ſort grows naturally in woods and near hedges, in lands which have lately been woods, in many parts of England, ſo is ſeldom admitted into gardens; but the poor people, who make it their buſineſs to gather the wild flowers of the fields and woods for noſegays, &c. bring great quantities of theſe in the ſpring to London, and ſell them about the ſtreets.

There is a variety of this with white flowers, which is kept in ſome gardens, which only differs in the colour of their flowers from the other.

The ſecond ſort is preſerved in ſome few gardens for the ſake of variety, but as it hath as little beauty as the firſt, ſo is ſeldom allowed a place in the flower-garden. The flowers of this are narrower than thoſe of the firſt ſort, and ſeem as if their petals were divided to the bottom, three of the outer ſegments being ſeparated from the other, ſtanding at a ſmall diſtance from the three interior, but they are all joined at their baſe; when the flowers firſt appear, they are of a light blue colour, but before they decay, they fade to a worn-out purple colour. This flowers early in the ſpring, and grows naturally in Spain and Mauritania.

The third ſort grows naturally in Spain and Italy; this hath blue flowers of the open ſpread bell-ſhape, which are divided into ſix ſegments almoſt to the bottom,

tom, and are diſpoſed on every ſide the ſtalk. The ſtalks riſe about nine inches high, and when the roots are ſtrong, the thyrſe of flowers is large. This flowers about the ſame time with the firſt ſort, and was formerly preſerved in gardens, but ſince there have been ſo many finer flowers raiſed from the ſeeds of the Eaſtern Hyacinths, theſe have been almoſt totally neglected, ſo that they are ſeldom ſeen but in old gardens

The fourth ſort ſeems to be a variety of the firſt, the flowers being ranged for the moſt part upon one ſide of the ſtalk, and the top of the ſpike is always bent on one ſide. The flowers are of a bluſh Peach colour, and appear about the ſame time as the firſt ſort.

The fifth ſort grows naturally in Spain; this hath a ſmaller flower than either of the former ſorts, and comes earlier in the ſeaſon. The petal is cut into ſix parts half the length, and is reflexed at the brim; the lower part is cylindrical, a little ſwelling at the baſe, and is of a deeper blue than either of the former. This was formerly called by the gardeners the Coventry blue Hyacinth.

The ſixth ſort is the Eaſtern Hyacinth, of which we formerly had no other varieties in the Engliſh gardens, but the ſingle and double white and blue flowering; but from the ſeeds of theſe there were a few others raiſed in England; and alſo by the Flemiſh gardeners, who came over annually with their flower-roots to vend in England; but the gardeners in Holland have within the laſt fifty years raiſed ſo many fine varieties, as to render the former ſorts of little or no value.

But thoſe who are deſirous to preſerve any of the old ſorts, need not be at much trouble about it, for their roots propagate in great plenty in any ſoil or ſituation, and will require no other care but to take up their roots every other or third year, ſoon after their leaves decay, and plant them again in autumn; for if they are permitted to remain longer in the ground, their roots will have multiplied to ſo great a degree, as to render their flowers very ſmall and weak, ſo of little worth.

All the different ſorts of Hyacinths are propagated by ſeeds or offſets from the old bulbs; the former method has been but little practiſed in England till very lately, but in Holland and Flanders it hath been followed for many years, whereby they have obtained a very great variety of the moſt beautiful flowers of this kind: and it is owing to the induſtry of the floriſts in thoſe countries, that the lovers and delighters in gardening are ſo agreeably entertained, not only with the curious variety of this, but of moſt other bulbous rooted flowers, few other floriſts thinking it worth their trouble to wait four or five years for the flowers of a plant, which when produced, perhaps there might not be one in forty that may deſerve to be preſerved; but they did not conſider that it was only the loſs of the four or five firſt years after ſowing, for if they continued ſowing every year after they began, there would be a ſucceſſion of flowers annually, which would conſtantly produce at leaſt ſome ſorts that might be different from what they had before ſeen; and new flowers being always the moſt valuable to ſkilful floriſts (provided they have good properties to recommend them) it would always be a ſufficient recompence for their trouble and loſs of time.

The method of raiſing theſe flowers from ſeed is as follows: having provided yourſelf with ſome good ſeed (which ſhould be ſaved from either ſemi-double, or ſuch ſingle flowers as are large, and have good properties) you muſt have a parcel of ſquare ſhallow boxes or pots, with holes in their bottoms to let off moiſture, which muſt be filled with freſh light ſandy ſoil, laying the ſurface very level; then ſow your ſeeds thereon as equally as poſſible, covering it about half an inch thick with the ſame light earth; the time for this work is about the middle or latter end of Auguſt. Theſe boxes, or pots, ſhould be placed where they may enjoy the morning ſun only until the latter end of September, at which time they ſhould be removed into a warmer ſituation, and towards the end of October they ſhould be placed under a common hot-bed frame, where they may remain during the winter and ſpring months, that they may be protected from hard froſts; though they ſhould be expoſed to the open air when the weather is mild, by taking off the glaſſes. In the latter end of February or the beginning of March, the young plants will begin to appear above ground, at which time they muſt be carefully ſcreened from froſts, otherwiſe they will be ſoon deſtroyed when they are ſo young; but you muſt never cover them at that ſeaſon but in the night, or in very bad weather; for when the plants are come up, if they are cloſe covered, they will draw up very tall and ſlender, and thereby prevent the growth of their roots. About the middle of April, if the weather proves good, you may remove the boxes out of the frame, placing them in a warm ſituation, obſerving, if the ſeaſon be dry, to refreſh them now and then gently with a little water, as alſo to keep them very clear from weeds, which would ſoon overſpread the tender plants, and deſtroy them, if permitted to remain.

Towards the beginning of May theſe boxes ſhould be removed into a cooler ſituation; for the heat of the ſun at that ſeaſon would be too great for theſe tender plants, cauſing their blades to decay much ſooner than they would naturally do, if they were ſcreened from its violence. In this ſhady ſituation they ſhould remain during the heat of ſummer, obſerving to keep them conſtantly clear from weeds; but you muſt not place them under the dripping of trees, &c. nor ſhould you give them any water after their blades are decayed, for that would infallibly rot the roots. About the latter end of Auguſt you ſhould ſift a little light rich earth over the ſurface of the boxes, and then remove them again into a warmer ſituation, and treat them, during the winter, ſpring, and ſummer months, as was before directed: and about the middle of Auguſt following you ſhould prepare a bed of light rich ſandy ſoil, in proportion to the quantity of your ſeedling plants; and having levelled the ſurface very even, you ſhould take the earth from the boxes in which your plants were raiſed, into a ſieve, in order to get out all the roots, which by this time, (if they have grown well) will be about the thickneſs of a ſmall quill; theſe roots ſhould be placed upon the bed at about two or three inches aſunder, obſerving to ſet the bottom part of their roots downwards; then cover them over two inches thick with the ſame light earth; but as it will be impoſſible to get all the ſmall roots out of the earth in the boxes, you ſhould ſpread the earth upon another bed equally, and cover it over with light earth; by which method you will not loſe any of the roots, be they ever ſo ſmall.

Theſe beds muſt be arched over with hoops, and in very hard froſty weather they muſt be covered with mats, &c. to protect them from froſt; and in the ſpring, when the green leaves are above ground, if the weather ſhould be very dry, you muſt refreſh them with water; but do this ſparingly, for nothing is more injurious to theſe bulbs than too great quantities of moiſture. During the ſummer ſeaſon you muſt conſtantly keep the beds clear from weeds; but after the blades are decayed, you muſt never give them any water; and in autumn you ſhould ſtir the ſurface of the bed with a very ſhort hand-fork, being exceeding careful not to thruſt it ſo deep as to touch the roots, which, if hurt, are very ſubject to periſh ſoon after. Then ſift a little freſh, light, rich earth over the bed about an inch thick, or ſomewhat more, and in winter cover them again (as was before directed.) In this bed the roots may continue two years, obſerving to treat them, both in ſummer and winter, as before; then the third year the roots ſhould be carefully taken up a little before their leaves decay, laying the roots horizontally in the ground to ripen for three weeks, after which they may be kept out of the ground till the end of Auguſt, when they ſhould be planted into new beds prepared as before, placing them at the diſtance of ſix inches aſunder; in theſe beds the roots may remain till they flower, during which time they ſhould be treated as before, with this difference only, that inſtead of covering them with mats in the winter, the ſurface of the ground ſhould be covered with tanners bark.

When their flowers begin to ſhew themſelves, you ſhould mark all ſuch as appear to have good properties, by thruſting a ſmall ſtick down by each root; which roots, at the time for taking them up, ſhould be ſelected from the reſt, and planted by themſelves; though I would by no means adviſe the rejecting any of the other roots, until they have blown two years, before which you cannot be aſcertained of their value. When the green leaves of theſe plants begin to decay, their roots muſt be taken up, and a bed of light earth, in a ſhady ſituation, ſhould be raiſed into a ridge; the better to ſhoot off the moiſture, the roots ſhould be laid into the earth again in an horizontal poſition, leaving the green leaves hanging out of the ground from the roots, whereby the great moiſture contained in their very ſucculent leaves and flower-ſtalks may be exhaled, and prevented from returning to the roots, which, when ſuffered ſo to do, is very often the cauſe of their rotting after they are out of the ground. In this ridge the roots ſhould remain until the leaves are quite dried off, when they muſt be taken up, and after being cleared of all manner of filth, which would be hurtful to them, they muſt be laid up in boxes, where they may be preſerved dry until September, which is the proper ſeaſon for planting them again; the method of doing this ſhall be hereafter mentioned, when we treat of the management of old roots.

I ſhall now proceed to the culture of ſuch Hyacinths as have either been obtained from Holland, or are of our own product from the ſeeds of ſuch flowers as were very beautiful, and worthy to be preſeved in collections of good flowers: and it hath been the want of ſkill in the management of theſe noble flowers, which has ocaſioned the ill ſucceſs moſt people have had with them in England, whereby they have been neglected, ſuppoſing their roots to degenerate after they have flowered in England, which is a great miſtake; for were the roots managed with the ſame art as hath been practiſed in Holland, I am fully convinced they would thrive near as well in England as there, or elſewhere, as I have experienced; for, from ſome hundreds of roots which I have received from Holland at two or three different times, I have had a very great increaſe of their roots, which were as large, and produced as many flowers upon their ſtems, as the ſame ſorts generally do in Holland.

The ſoil in which theſe flowers ſucceed beſt, is a light, ſandy, freſh, rich earth, which may be compoſed after the following manner: take half freſh earth from a common, or paſture land, which is chiefly of a ſandy loam; this ſhould be off the ſurface, and not taken above eight or nine inches deep at moſt; and if you take the turf, or green ſward with it, it will ſtill be better, provided you have time to let it rot before it is uſed; to this you ſhould add a fourth part of ſea-ſand, and the other fourth part of rotten cow dung; mix theſe well together, and caſt it into a heap, where it may remain until you uſe it, obſerving to turn it over once in three weeks or a month, that it may be well mixed. If this compoſt is made two years before it is uſed, it will be much the better; but if you are obliged to uſe it ſooner, then it ſhould be oftener turned, that the parts may the better unite.

This ſoil ſhould be laid two feet deep on the beds which are deſigned for Hyacinths, and if you lay a little rotten cow dung, or tanners bark, at the bottom, which may be within reach of the fibres, but ſhould by no means touch the bulb, it will be better. If the ſoil is very wet where theſe beds are made, you ſhould raiſe them ten or twelve inches above the ſurface of the ground; but if it be dry, they need not be raiſed above three or four inches.

The manner of preparing the beds is as follows: Firſt, take all the former old earth out of the bed to the depth you intend, which ſhould be near three feet; then ſpread ſome rotten neats dung, or tan, in the bottom, about ſix inches thick, laying it very level; upon this you ſhould lay the above-mentioned earth two feet thick, levelling it very even; then ſcore out the diſtances for the roots, which ſhould be eight inches ſquare, in ſtrait rows each way; after which, place your roots exactly in the ſquares, obſerving to ſet the bottom part downward; then cover the roots ſix inches deep with the ſame prepared earth, being very careful in doing this not to diſplace any of the roots; and if the tops of theſe beds are made a little rounding, to ſhoot off the wet, it will be of ſervice in moiſt ground, provided the middle of the beds are not made too high, which is a fault the other way.

The beſt ſeaſon for planting theſe roots is the middle or latter end of September, according to the earlineſs or lateneſs of the ſeaſon, or the weather when it happens; but I would adviſe you never to plant them when the ground is extreme dry, unleſs there be a proſpect of ſome rain ſoon after; for if the weather ſhould continue dry for a conſiderable time after, the roots will receive a mouldineſs, which will certainly deſtroy them. The beds will require no farther care until the froſt comes on very ſevere, at which time they ſhould have ſome rotten tan ſpread over them, about four inches thick; and if the alleys on each ſide of the bed are filled up, either with rotten tan, dung, or ſand, it will prevent the froſt from penetrating the ground on each ſide to the roots, and ſecure them from being deſtroyed; but when the winters prove very ſevere, it will alſo be proper to have ſome Peas-haulm, Straw, or ſuch like covering laid over them, which will keep out the froſt better than mats; and lying hollow, will admit the air to the ſurface of the ground, and alſo permit the exhalations to paſs off, whereby the earth will remain dry, and prevent the roots from rotting, which has often happened when the beds have been too cloſe covered. But you muſt obſerve to take off this light covering whenever the weather is mild, and only let it continue on in very hard froſts; for where the beds are covered with tan or ſea-coal aſhes, no common froſt can penetrate through, ſo the coverings are uſeleſs, except in very ſevere froſt; for a ſmall froſt cannot injure the roots before the green leaves appear above ground, which is ſeldom before the beginning of February, at which time the beds muſt be arched over with hoops, that they may be covered either with mats, canvas, or ſome other light covering, to prevent the froſt from injuring the buds as they ariſe above ground; but theſe coverings muſt be conſtantly taken off every day when the weather is mild, otherwiſe the flower-ſtems will be drawn up to a great height, and become very weak, and the foot-ſtalks of the flowers will be long and ſlender, and ſo rendered incapable of ſupporting the bells; which is a great diſadvantage to the flowers, for one of their greateſt beauties conſiſts in the regular diſpoſition of their bells. When theſe hoops are fixed over the beds, the rotten tan ſhould be moſt of it taken off them; in doing of which, great care ſhould be taken not to bruiſe or injure the leaves of the Hyacinths, which by that time will be breaking out of the ground with the flower-ſtem, therefore the tan ſhould be removed by the hands; or if any inſtrument is made uſe of in the doing of it, there muſt be great caution how it is performed.

When the ſtems of the flowers are advanced to their height before the flowers are expanded, you ſhould place a ſhort ſtick down by each root, to which, with a wire formed into a hoop, the ſtem of the flowers ſhould be faſtened, to ſupport them from falling; otherwiſe, when the bells are fully expanded, their weight will incline them to the ground, eſpecially if they are not ſcreened from the wind and rain.

During their ſeaſon of flowering they ſhould be covered in the heat of the day from the ſun, as alſo from all heavy rains; but they ſhould be permitted to receive all gentle ſhowers, as alſo the morning and evening ſun; but if the nights are froſty, they muſt be conſtantly defended therefrom. With this management you may continue your Hyacinths in beauty at leaſt one whole month, and ſometimes more, according to their ſtrength, or the favourableneſs of the ſeaſon.

When their flowers are quite decayed, and the tops of their leaves begin to change their colour, you muſt carefully raiſe the roots out of the ground with a narrow ſpade, or ſome other handy inſtrument; this is what the Dutch gardeners term lifting of them: in the doing of this, the inſtrument muſt be carefully thruſt down by the ſide of the root, being careful not to bruiſe or injure it, as alſo to put it below the bottom of the root; then by the forcing of this inſtrument on one ſide, the fibres of the root are raiſed and ſeparated from the ground. The deſign of this is, to prevent their receiving any more nouriſhment from the ground; for by imbibing too much moiſture at this ſeaſon, the roots frequently rot after they are taken up: about a fortnight after this operation the roots ſhould be entirely taken out of the ground, and then carried to beds ſituated where the morning ſun only ſhines upon them; the earth of the beds ſhould be looſe and raiſed into a ſharp ridge, laying the roots into it in a horizontal poſition, with their leaves hanging out, by which means a great part of the moiſture contained in their thick ſucculent ſtalks and leaves will evaporate; which, if it were permitted to return back to the roots, would cauſe them to rot and decay after they are taken up, which has been the general defect of moſt of the Hyacinths in England.

In this poſition the roots ſhould remain until the green leaves are entirely decayed, which perhaps may be in three weeks time. This is what the Dutch gardeners term the ripening of their roots, becauſe by this method the roots become firm, and the outer cover is ſmooth, and of a bright purple colour; whereas thoſe roots which are permitted to remain undiſturbed, till the leaves and ſtalks are quite decayed, will be large, ſpongy, and their outer coats will be of a pale colour; for the ſtems of many of theſe flowers are very large, and contain a great quantity of moiſture, which, if ſuffered to return into the roots, will infallibly cauſe many of them to periſh. After they are ſo ripened, you muſt take them out of the ground, and wipe them clean with a ſoft woollen cloth, taking off all the decayed parts of the leaves and fibres, putting them into open boxes where they may lie ſingly, and be expoſed to the air, but they muſt be preſerved carefully from moiſture; nor ſhould they be ſuffered to remain where the ſun may ſhine upon them; in this manner they may be preſerved out of the ground until September, which is the ſeaſon for planting them again, at which time yon muſt ſeparate all the ſtrong flowering roots, planting them in beds by themſelves, that they may make an equal appearance in their flowers; but the offsets and ſmaller roots ſhould be planted in another ſeparate bed for one year, in which time they will acquire ſtrength, and by the ſucceeding year will be as ſtrong as the older roots.

The ſingle and ſemi-double flowers ſhould be planted alſo in a bed by themſelves, where they ſhould be carefully ſheltered (as was directed before) from the froſt, until the flowers are blown; at which time their covering ſhould be entirely removed, and they ſuffered to receive the open air, but the flower-ſtalks ſhould be ſupported with ſticks; which, though the weather may ſoon deface the beauty of the flowers, yet is abſolutely neceſſary to promote their ſeeding; and when the ſeeds are quite ripe, you muſt cut off the veſſels and preſerve them, with the ſeeds therein, until the ſeaſon for ſowing it. But you muſt obſerve, that after theſe flowers have produced ſeeds, they ſeldom flower ſo well again, at leaſt not in two years after; ſo that the beſt method to obtain good ſeeds is, to plant new roots every year for that purpoſe. Although theſe roots are, by moſt perſons, taken up every year, yet if the beds are well prepared for them, they may remain two years in the ground unremoved, and the roots will increaſe more the ſecond year than the firſt, though the flowers are more liable to degenerate; therefore thoſe who cultivate theſe for ſale, take up their roots annually when they are large and ſaleable; but the offsets and ſmall roots, they uſually leave two years in the ground.

There are ſome perſons who let their Hyacinth roots remain three or four years unremoved, by which they have a much greater increaſe of roots, than when they are annually taken up; but the roots by this great increaſe are frequently degenerated, ſo as to produce ſingle flowers; therefore I ſhould adviſe the taking up of the roots every year, eſpecially thoſe of the moſt valuable kinds, which is the moſt certain method to preſerve them in their greateſt perfection, though the increaſe may not be ſo great; and if theſe roots are planted a fortnight or three weeks earlier in the autumn than is before directed, it will cauſe them to produce ſtronger flowers; and thoſe roots which are annually removed, will be rounder and firmer than ſuch as ſtand two years unremoved.

For the other ſorts of Hyacinth, ſee Muscari and Ornithogalum.

HYACINTHUS TUBEROSUS. See Crinum and Polyanthes.

HYDRANGEA. Gron. Flor. Virg. 50. Lin. Gen. Plant. 492. We have no Engliſh title for this genus.

The Characters are,

The flower hath a ſmall permanent empalement of one leaf, indented in five parts, and five roundiſh petals which are equal, and larger than the empalement. It hath ten ſtamina which are alternately longer than the petal, terminated by roundiſh ſummits. Under the flower is ſituated a roundiſh germen, ſupporting two ſhort ſtyles ſtanding apart, crowned by permanent obtuſe ſtigmas. The germen afterward turns to a roundiſh capſule, crowned by the two horned ſtigmas, divided tranſverſly into two cells, filled with ſmall angular ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's tenth claſs, intitled Decandria Dygynia, which includes the plants whoſe flowers have ten ſtamina and two ſtyles.

We have but one Species of this genus, viz.

Hydrangea (*Arboreſcens.*) Gron. Flor. Virg. 50.

This plant grows naturally in North America, from whence it has been brought within a few years paſt to Europe, and is now preſerved in gardens for the ſake of variety more than its beauty. It hath a ſpreading fibrous root, from which is ſent up many ſoft, pithy, ligneous ſtalks, which riſe about three feet high, garniſhed at each joint with two oblong heart-ſhaped leaves placed oppoſite, ſtanding upon foot-ſtalks about one inch long; the leaves are three inches long, and two broad near their baſe, ſawed on their edges, and have many veins running from the mid-rib upward to their borders; they are of a light green, and fall away in the autumn; the flowers are produced at the top of the ſtalks, in form of a corymbus; they are white, compoſed of five petals, with ten ſtamina ſurrounding the ſtyle. Theſe appear toward the end of July and in Auguſt, but ſeldom perfect their ſeeds in England.

This is eaſily propagated by parting of the roots; the beſt time for this is the latter end of October, which is alſo the beſt time to tranſplant them: the plants ſhould have a moiſt ſoil, for they grow naturally in marſhy places; they require no other culture but to keep them clear from weeds, and dig the ground between them every winter. The roots are perennial, and if in very ſevere froſt the ſtalks are killed, they will put out new ones the following ſpring.

HYDRASTIS. See Warneria.

HYDROCOTYLE, [of ὕδωρ, water, and κοτύλη, a cavity; becauſe this plant has a cavity in the leaves which contains water, and the plant grows in marſhes.] Water Navelwort.

This plant grows in great plenty in moiſt places in moſt parts of England, and is never cultivated for uſe, ſo I ſhall paſs it over with only naming it.

HYDROLAPATHUM. See Rumex.

HYDROPHYLLON. Lin. Gen. Plant. 187. Hydrophyllon. Tourn. Inſt. R. H. 81. tab. 16. Water Leaf.

The Characters are,

The flower has a permanent empalement of one leaf, cut into five ſegments which ſpread open. It hath one bell-ſhaped petal, which is divided into five parts, indented at their points; under each of theſe ſegments is fixed a nectarium, which is ſituated about the middle, and ſhut up lengthways by two lamellæ. It hath five ſtamina which are longer than the petal, terminated by oblong proſtrate ſummits, and an oval-pointed germen, ſupporting an awl-ſhaped ſtyle the length of the ſtamina, crowned by a bifid ſpreading ſtigma. The germen afterward becomes a globular capſule with one cell, incloſing one large round ſeed.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, which includes the plants whoſe flowers have five ſtamina and one ſtyle.

We know but one Species of this genus, viz.

Hydrophyllon (*Virginianum*) foliis pinnatifidis. Lin. Sp. 208. Morini. Joncq. Hort. *Water Leaf with wing-pointed leaves.*

This plant grows naturally in many parts of North America, on moiſt ſpongy ground. The root of it is compoſed of many ſtrong fleſhy fibres, which ſpread wide on every ſide, from which ariſe many leaves with foot-ſtalks five or ſix inches long, which are jagged into three, five, or ſeven lobes, almoſt to the midrib; theſe are indented on their edges, and have ſeveral veins running from the midrib to the ſides; they are of a lucid green, and in the ſpring have water ſtanding on the cavities, from whence I ſuppoſe Morinus gave it the title of Water Leaf, and not from the plant growing in water, as Tournefort conjectures. The flowers riſe with foot-ſtalks from the root, having one or two ſmall leaves of the ſame ſhape with the lower; the flowers are produced in looſe cluſters hanging downward; they are of a dirty white and bell-ſhaped, ſo make no great figure. They appear in June, and the ſeeds ſometimes ripen here in Auguſt.

This plant is very hardy in reſpect to cold, but it ſhould be planted in a moiſt rich ſoil; for if it is planted in a dry warm ſoil, it will not live, unleſs it is conſtantly watered in dry weather. It may be propagated by parting of the roots, which ſhould be done in autumn, that the plants may be well rooted before ſpring, for otherwiſe they will require a great deal of water. It requires a moiſt ſoil and ſhady ſituation.

HYDROPIPER, the common biting Arſe-ſmart, which grows in great plenty in moiſt places near ditches ſides almoſt every where.

HYDROSTATICS [ὑδροστατικὴ, of ὕδωρ, water, and στατικὴ, of στατὸς, ſtanding, of ἵστημι, I ſtand or ſtop; Hydroſtatics being conceived as the doctrine of the æquillibrum of liquors,] or the doctrine of the gravitation of fluid; or it is that part of the mechanics which conſiders the weight or gravity of fluid bodies; particularly of water, and of ſolid bodies immerged therein.

To Hydroſtatics belongs whatever relates to the gravities and æquilibria of liquors, with the art of weighing bodies in water, in order to eſtimate their ſpecific gravities.

Of the uſe of this ſcience in horticulture, the Rev. Dr. Hales, in his excellent Treatiſe of Vegetable Staticks, has given many examples, by experiments, ſhewing the quantities of moiſture imbibed and perſpired by plants and trees, neceſſary to be known, in order to promote the buſineſs of vegetation.

Some of the moſt uſeful heads of this ſcience are;

1. That the upper parts of all fluids preſs upon the lower.

2. That a lighter fluid may gravitate or preſs upon a heavier.

3. That if a body that is contiguous to the water, be altogether, or in part, lower than the upper ſurface of the water, the lower part of the body will be preſſed upwards by the water which touches it beneath.

4. There needs only a competent weight of an external fluid, to account for the riſing of water in pumps, &c.

5. If a body be placed under water, ſo that its uppermoſt ſurface lie parallel to the horizon, the direct preſſure that it ſuſtains is no more than that of a column of water, whoſe baſe is the horizontal ſuperficies of the body, and its heighth the perpendicular depth of the water. And if the water which leans on the body be contained in pipes which are open at both ends, the preſſure of the water is to be eſtimated by the weight of a pillar of water, the baſe of which is equal to the lower orifice of the pipe, and whoſe height is equal to a perpendicular, which reaches from thence to the top of the water, although the pipe ſhould be much inclined any way, or though it ſhould be ever ſo regularly ſhaped, and much broader in ſome other place than the bottom.

6. A body which is immerſed in a fluid, ſuſtains a natural preſſure from the fluid, which alſo increaſes as the body is placed deeper beneath the ſurface of the fluid.

7. The reaſon why water aſcends in ſiphons, and by which it flows through them, may be explained from the external preſſure of ſome other fluid, without having recourſe to the abhorrence of a vacuum.

8. The moſt ſolid body, which will ſink by its own weight at the ſurface, yet if it be placed at a depth twenty times greater than that of its own thickneſs it will not ſink, if its deſcent be not aſſiſted by the incumbent water.

9. If a body which is ſpecifically lighter than a fluid, be immerſed in that fluid, it will riſe with a force proportionable to the exceſs of gravity in that fluid.

10. If a body which is heavier than a fluid be immerſed, it will ſink with a force that is proportionable to the exceſs of its gravity.

11. If any veſſel be filled with water, or any other liquor, the ſurface of which is capable of being even, it will continue ſo till diſturbed by ſome other external cauſe.

12. When the fluids are preſſed, they are preſſed undiquaque, i. e. on all ſides.

How far the knowledge of any of theſe properties of fluids may conduce to the philoſophical improvement of gardening, and the buſineſs of vegetation, will be more clearly perceived when well conſidered by the ingenious artiſt, than being ſet forth by words.

HYGROMETER [ὑγρόμετρον, of ὑγρὸς, moiſt, and μέτρον, meaſure, of μετρέω, to meaſure,] is a machine or inſtrument contrived to ſhew or meaſure, the moiſtneſs and drineſs of the air, according as it abounds with moiſt or dry vapours, and to meaſure and eſtimate the quantity of ſuch moiſtneſs and drineſs.

There are divers kinds of Hygrometers; for whatever body either ſwells or ſhrinks by drineſs or moiſture, is capable of being formed into an Hygrometer; ſuch are the woods of moſt kinds, particularly Aſh, Deal, Poplar, &c. ſuch alſo is a cord, catgut, &c.

Stretch a hempen cord or fiddle-ſtring along a wall, bringing it over a truckle or pully; and to the other end tie a weight, unto which fit a ſtyle or index; on the ſame wall fit a plate of metal, divided into any number of equal parts, and the Hygrometer is complete.

For it is a matter of undoubted obſervation, that moiſture ſenſibly ſhortens the length of cords and ſtrings; and that as the moiſture evaporates, they return to their former length, and the like may be ſaid of a fiddle-ſtring.

The weight therefore, in the preſent caſe, upon an increaſe of the moiſture of the air, will aſcend, and upon a diminution of the ſame will deſcend.

Hence, as the index will ſhew the ſpaces of aſcent and deſcent, and thoſe ſpaces are equal to the increments and decrements of the length of the cord or gut, the inſtrument will diſcover whether the air be more or leſs humid now, than it was at another given time.

The ordinary contrivance with whip-cord is one of the eaſieſt, for that will infallibly ſhorten and lengthen as the air grows moiſter and drier.

Some recommend a cat-gut as the beſt, which may be a yard in length ſuſpended, having a plumbet or piece of lead, with an index or pointer hanging at the lower end, by means of which the cat-gut will twiſt or untwiſt as the air dries or moiſtens, and ſhorten and lengthen ſo as to raiſe and ſink the plumbet with the index, and this index will point out the degree ſought for.

The weight of this lead or plumbet, ſhould be about two ounces.

Some perſons who approve a fine whip-cord inſtead of cat-gut, uſe a greater weight of lead; the twiſting and untwiſting of the cat gut or whip-cord, will make the lead with the index turn round, as well as riſe and fall. The degrees may be made upon an open ſcrew of braſs within, with which the plumbet and index has its motion.

When you are provided with a barometer and Hygrometer, compare the motions of the one with the other, in order to judge what proportion the riſe or fall of the quickſilver in the barometer bears to the twiſting of the cat-gut or whip-cord; the degrees of which motion may be obſerved by the index or pointer of the Hygrometer; and at the ſame time both theſe muſt be compared with the riſing and falling of the ſpirit in a thermometer, to know what degree of heat or cold attends every different change of weather.

HYGROSCOPE [of ὑγρὸς, moiſt, and σκοπέω, to view or conſider,] a machine the ſame as the hygrometer, and for the ſame uſes.

Theſe inſtruments are of good uſe in conſervatories, for meaſuring or ſhewing the dampneſs or drineſs of them in the winter ſeaſon.

HYMENÆA. Lin. Gen. Plant. 512. Courbaril. Plum. Nov. Gen. 49. tab. 14. Locuſt-tree.

The Characters are,

The outward involucrum of the flower is divided into two parts, the inward is of one leaf, indented in five parts; the flower hath five petals, which are equal in ſize, and ſpread open. It hath ten declining ſtamina, which are ſhort, terminated by oblong ſummits. In the center is ſituated an oblong germen, ſupporting a declining ſtyle, crowned by an acute ſtigma; the germen afterward becomes a large oblong pod, with a thick ligneous ſhell, divided into ſeveral partitions tranſverſly, in each of which is lodged one compreſſed large ſeed, ſurrounded with a farinaceous pulp.

This genus of plants is ranged in the firſt ſection of Linnæus's tenth claſs, intitled Decandria Monogynia, which includes the plants whoſe flowers have ten ſtamina and one ſtyle.

We know but one Species of this genus, viz.

Hymenæa (*Courbaril.*) Hort. Cliff. 484. *Locuſt-tree.* Courbaril bifolia, flore pyramidato. Plum. Nov. Gen. 49. *Two-leaved Courbaril with a pyramidal flower, commonly called Locuſt-tree in America.*

This is a very large ſpreading tree in the Weſt-Indies, where it grows in great plenty: it hath a large ſtem, covered with a ruſſet bark, which divides into many ſpreading branches, garniſhed with ſmooth ſtiff leaves, which ſtand by pairs, their baſe joining at the foot-ſtalk, to which they ſtand oblique, one ſide being much broader than the other, the two outer ſides being rounded, and their inſide ſtrait, ſo that they reſemble a pair of ſheep-ſhears; they are pointed at the top, and ſtand alternately on the ſtalk. The flowers are produced in looſe ſpikes at the end of the branches, ſome of the ſhort ligneous foot-ſtalks ſupporting two, and others three flowers, which are compoſed of five yellow petals ſtriped with purple; the petals are ſhort and ſpread open; the ſtamina are much longer, and of a purpliſh colour; theſe flowers are ſucceeded by thick, fleſhy, brown pods, ſhaped like thoſe of the Garden Bean; they are ſix inches long, and two inches and a half broad, of a purpliſh brown colour, and a ligneous conſiſtence, with a large ſuture on both edges; theſe contain three or four roundiſh compreſſed ſeeds, divided by tranſverſe partitions.

The wood of this tree is eſteemed as good timber in the Weſt-Indies, and it yields a fine clear reſin which is called gum anime in the ſhops, which makes an excellent varniſh.

It is eaſily raiſed from the ſeeds if they are freſh; theſe muſt be ſown in pots, and plunged into a hot-bed of tanners bark: there ſhould be but one ſeed put into each pot, or if there is more, when the plants appear, they ſhould be all drawn out to one ſoon after they come up, before their roots entangle, when it will be hazardous doing it; for if great care is not taken, the plant intended to be left may be drawn out with the other. As the roots of this plant are but ſlender, ſo they are very difficult to tranſplant; for unleſs a ball of earth is preſerved to their roots, they ſeldom ſurvive their removal, therefore they muſt be ſeldom tranſplanted from one pot to another. The plants muſt conſtantly remain in the tan-bed in the ſtove, and ſhould be treated in the ſame way with other tender plants of the ſame country, giving but little water to them, eſpecially in the winter. When theſe plants firſt appear, they make conſiderable progreſs for two or three months, after which time they are at a ſtand perhaps a whole year without ſhooting, being in their growth very like the Anacardium, or Caſhew Nut, ſo is very difficult to preſerve long in this country.

HYOSCYAMUS. Tourn. Inſt. R. H. 117. tab. 42. Lin. Gen. Plant. 218. [of ὗς, a ſwine, and κύαμος, a Bean, q. d. Hog's-bean,] Henbane; in French, *Juſquaime.*

The Characters are,

The flower has a cylindrical empalement of one leaf, which is permanent, ſwelling at the bottom, and cut into five acute ſegments at the top. It hath one funnel-ſhaped petal, with a ſhort cylindrical tube, and an erect ſpreading rim, cut into five obtuſe parts, one being larger than the others; it hath five inclined ſtamina, terminated by roundiſh ſummits. In the center is ſituated a roundiſh germen, ſupporting a ſlender ſtyle, crowned by a round ſtigma. The germen afterward becomes an oval obtuſe capſule ſitting in the empalement, divided in two cells by an intermediate partition, opening with a lid at the top, to let out the many ſmall ſeeds which adhere to the partition.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, in which he includes thoſe plants whoſe flowers have five ſtamina and one ſtyle.

The Species are,

1. Hyoscyamus (*Niger*) foliis amplexicaulibus ſinuatis, floribus ſeſſilibus. Hort. Cliff. 56. *Henbane with ſinuated leaves embracing the ſtalks, and ſeſſile flowers.* Hyoſcyamus vulgaris, vel niger. C. B. P. *Common Black Henbane.*
2. Hyoscyamus (*Major*) foliis petiolatis, floribus pedunculatis terminalibus. *Henbane with leaves having foot-ſtalks, and flowers with foot-ſtalks terminating the branches.* Hyoſcyamus major, albo ſimilis, umbilico floris atro-pupureo. T. Cor. *Great Henbane like the white, but with a dark purple bottom to the flower.*
3. Hyoscyamus (*Albus*) foliis petiolatis, floribus ſeſſilibus. Hort. Upſal. 56. *Henbane with leaves having foot-ſtalks, and flowers ſitting cloſe to the branches.* Hyoſcyamus major, albo ſimilis, umbilico floris virenti. Juſſieu. *Greater Henbane like the white, with a green bottom to the flower.*
4. Hyoscyamus (*Minor*) foliis petiolatis, floribus ſolitariis lateralibus. *Henbane with leaves having foot-ſtalks, and flowers proceeding ſingly from the ſides of the branches.* Hyoſcyamus minor albo ſimilis, umbilico floris atro purpureo. Tourn. Cor. 5. *Smaller Henbane like the white, with a dark purple bottom to the flower.*
5. Hyoscyamus (*Reticulatis*) foliis caulinis petiolatis cordatis ſinuatis acutis, floribus integerrimis, corollis ventricoſis. Lin. Sp. 257. *Henbane with heart-ſhaped,*

ſinuated, acute leaves upon foot-ſtalks, and entire ſwollen flowers. Hyoſcyamus rubello flore. C. B. P. *Henbane with a reddiſh coloured flower.*

6. HYOSCYAMUS (*Aureus*) foliis petiolatis eroſo-dentatis acutis, floribus pedunculatis fructibus pendulis. Lin. Sp. 257. *Henbane with acute indented leaves ſtanding on foot-ſtalks, the flower having foot-ſtalks, and the fruit hanging.* Hyoſcyamus Creticus luteus major. C. B. P. *Greater yellow Henbane of Candia.*
7. HYOSCYAMUS (*Puſillus*) foliis lanceolatis dentatis, floralibus inferioribus binis, calycibus ſpinoſis. Hort. Upſal. 44. *Henbane with ſpear-ſhaped indented leaves, and a prickly empalement.* Hyoſcyamus puſillus aureus Americanus, antirrhini foliis glabris. Pluk. Alm. 188. tab. 37. fol. 5. *Low, golden, American Henbane, with a ſmooth Snapdragon leaf.*

The firſt of theſe ſorts is very common in England, growing upon the ſides of banks and old dunghills almoſt every where. It is a biennial plant with long fleſhy roots, which ſtrike deep into the ground, ſending out ſeveral large ſoft leaves, which are deeply ſlaſhed on their edges, and ſpread on the ground; the following ſpring the ſtalks come out, which riſe about two feet high, garniſhed with leaves of the ſame ſhape, but ſmaller, which embrace the ſtalks with their baſe; the upper part of the ſtalk is garniſhed with flowers ſtanding on one ſide in a double row, ſitting cloſe to the ſtalks alternately; theſe are of a dark purpliſh colour with a black bottom, and are ſucceeded by roundiſh capſules, ſitting within the empalement; theſe open with a lid at the top, and have two cells filled with ſmall irregular ſeeds. This is a very poiſonous plant, and ſhould be rooted out in all places where children are ſuffered to come; for in the year 1729, there were three children poiſoned with eating the ſeeds of this plant, near Tottenham-court; two of which ſlept two days and two nights before they could be awakened, and were with difficulty recovered; but the third being older and ſtronger, eſcaped better.

The roots of this plant are uſed for anodyne necklaces to hang about children's necks, being cut to pieces and ſtrung like beads, to prevent fits and cauſe an eaſy breeding of their teeth, but they are very dangerous to uſe inwardly. For ſome years paſt there was a mixture of theſe roots brought over with Gentian, and uſed as ſuch, which was attended with very bad effects, as hath been mentioned under the article of Gentian, ſo I ſhall not repeat it here.

The ſecond ſort grows naturally in the iſlands of the Archipelago. This hath rounder leaves, which are obtuſely ſituated upon their borders, and ſtand upon foot-ſtalks; the ſtalks branch more than thoſe of the firſt, and the flowers grow in cluſters toward the end of the branches, ſtanding upon ſhort foot-ſtalks; they are of a pale yellow colour, with very dark purple bottoms.

The third ſort is much like the ſecond, but the flowers are in larger bunches, ſitting very cloſe on the ends of the branches; they are of a greeniſh yellow colour, with green bottoms. It grows naturally in the warm parts of Europe, and is the ſort whoſe ſeeds ſhould be uſed in medicine, being the white Henbane of the ſhops.

The fourth ſort was brought from the Levant by Dr. Tournefort. This hath a ſmaller ſtalk than either of the former, whoſe joints are further diſtant; the leaves are roundiſh, and deeply indented in obtuſe ſegments, ſtanding upon pretty long foot-ſtalks; the flowers come out ſingly from the ſide of the ſtalks, at a good diſtance from each other; they are of a yellow colour with dark bottoms.

The fifth ſort grows naturally in Syria; this riſes with a branching ſtalk two feet high, garniſhed with long ſpear-ſhaped leaves having foot-ſtalks; the lower leaves are regularly cut on both ſides into acute ſegments which are oppoſite, ſo are ſhaped like the winged leaves, but the upper leaves are entire; the flowers grow at the end of the ſtalks in bunches; they are of a worn-out red colour, and ſhaped like thoſe of the common ſort, but their tubes are ſwollen.

All theſe are biennial plants, which periſh ſoon after they have perfected their ſeeds. They flower in June and July, and their ſeeds ripen in the autumn, which, if permitted to ſcatter, will produce plenty of the plants the following ſpring; or if the ſeeds are ſown at that ſeaſon, they will ſucceed much better than in the ſpring; for when they are ſown in ſpring, the plants ſeldom come up the ſame year. They are all hardy except the fifth ſort, and require no other culture but to keep them clean from weeds, and thin the plants where they are too cloſe. The fifth ſort ſhould have a warm ſituation and a dry ſoil, in which it will live much better through the winter than in rich ground.

The ſixth ſort grows naturally in Candia; this is a perennial plant with weak ſtalks, which require a ſupport; the leaves are roundiſh, and acutely indented on their edges, ſtanding upon pretty long foot-ſtalks; the flowers come out at each joint of the ſtalk; they are large, of a bright yellow, with a dark purple bottom; the ſtyle of this ſort is much longer than the petal. It flowers moſt part of ſummer, and ſometimes ripens ſeeds in the autumn. If theſe ſeeds are ſown in pots as ſoon as they are ripe, and placed under a hot-bed frame in winter, the plants will come up in the ſpring; but if they are kept out of the ground till ſpring, they rarely ſucceed. This ſort will continue ſeveral years, if they are kept in pots and ſheltered in winter, for they will not live in the open air at that ſeaſon, but it only requires to be protected from froſt; therefore if theſe plants are placed under a common hot-bed in winter, where they may enjoy as much free air as poſſible in mild weather, they will thrive better than when they are more tenderly treated. This ſort may be eaſily propagated by cuttings, which, if planted in a ſhady border during any of the ſummer months, will take root in a month or ſix weeks, and may be afterward planted in pots, and treated like the old plants.

HYPECOUM. Tourn. Inſt. R. H. 230. tab. 115. Hypecoum; Lin. Gen. Plant. 157. We have no Engliſh name for this plant.

The CHARACTERS are,

The empalement of the flower is compoſed of two ſmall oval leaves, which are oppoſite and erect. The flower hath four petals; the two outer which are oppoſite, are broad, and divided into three obtuſe lobes; the two other which are alternate, are cut into three parts at their points. It hath four ſtamina ſituated between the petals, which are terminated by oblong ſummits. In the center is placed an oblong cylindrical germen, ſupporting two ſhort ſtyles, crowned by acute ſtigma. The germen afterward becomes a long, compreſſed, jointed pod, which is incurved, with one roundiſh compreſſed ſeed in each joint.

This genus of plants is ranged in the ſecond ſection of Linnæus's fourth claſs, which contains the plants whoſe flowers have four ſtamina and two ſtyles.

The SPECIES are,

1. HYPECOUM (*Procumbens*) ſiliquis arcuatis compreſſis articulatis. Hort. Upſal. 31. *Hypecoum with compreſſed jointed pods bent inward.* Hypecoum latiore folio. Tourn. *Broad-leaved Hypecoum.*
2. HYPECOUM (*Pendulum*) ſiliquis cernuis teretibus cylyndricis. Hort. Upſal. 31. *Hypecoum with taper, cylindrical, nodding pods.* Hypecoum tenuiore folio. Tourn. *Narrow-leaved Hypecoum.*
3. HYPECOUM (*Erectum*) ſiliquis erectis teretibus toruloſis. Hort. Upſal. 32. *Hypecoum with taper, erect, wreathed pods.* Hypecoum ſiliquis erectis teretibus. Amm. Ruth. 58. *Hypecoum with erect taper pods.*

The firſt ſort hath many wing-pointed leaves of a grayiſh colour, which ſpread near the ground, and ſlender branching ſtalks, which lie proſtrate on the ſurface of the ground; theſe are naked below, and at the top are garniſhed with two or three ſmall leaves of the ſame ſhape and colour with the under ones; from between theſe leaves come out the foot-ſtalks of the flower, each ſuſtaining one yellow flower with four petals, and a pointal ſtretched out beyond the petals, which afterward turns to a jointed compreſſed pod about three inches long, which bends inward like a bow, having one roundiſh compreſſed ſeed in each joint. This flowers in June and July, and the ſeeds ripen in Auguſt.

The ſecond ſort hath ſlender ſtalks which ſtand more erect, and the ſegments of the leaves are longer and much narrower than thoſe of the firſt; the flowers are ſmaller, and come out at the diviſion of the branches; theſe are ſucceeded by narrow taper pods, which hang downward. It flowers and ſeeds at the ſame time with the firſt.

The third ſort grows in the eaſt; Dr. Amman received the ſeeds from Dauria, and I received the ſeeds from Iſtria, where it was found growing naturally. This hath much the appearance of the ſecond ſort in leaf and flower, but the pods grow erect, and are wreathed and twiſted about. It flowers and ſeeds at the ſame time with the others.

Theſe plants are all of them annual, ſo their ſeeds ſhould be ſown ſoon after they are ripe, otherwiſe it will be a year before the plants will appear, on a bed of light freſh earth where they are to remain, for they ſeldom ſucceed if they are tranſplanted. When the plants are come up, they ſhould be carefully cleared from weeds; and where the plants are too cloſe, they muſt be thinned, leaving them about ſix or eight inches apart; after this they will require no other culture, but to keep them conſtantly clear from weeds. In June theſe plants will flower, and their ſeeds will be ripe in Auguſt.

When the ſeeds are ſown in the ſpring, and the ſeaſon proves dry, the ſeeds will not grow the firſt year; but if the ground is kept clear from weeds and not diſturbed, the plants will come up the following ſpring. I have known the ſeeds of theſe plants remain in the ground two years, and the plants have come up the third ſpring very well; ſo that it will be very proper to ſow ſome of the ſeeds in autumn, ſoon after they are ripe, in a warm border, where the plants may come up early the following ſpring; and theſe will be ſtronger, and more likely to perfect ſeeds, than thoſe ſown in the ſpring, by which method the kinds may be preſerved.

If the ſeeds of theſe plants are permitted to ſcatter, the plants will come up the following ſpring without any care; and if they are treated in the ſame way as the others, they will thrive equally; but when the ſeeds are ſown in the ſpring, they ſhould be taken out of the pods, and diveſted of their fungous covering, which adheres cloſe to them, ſo prevents their growing, till that is rotted and decayed.

Theſe plants are ſeldom propagated but by thoſe who are curious in botany, though for the ſake of variety they may have a place in large gardens, becauſe they require very little trouble to cultivate them; and as they take up but little room, ſo they may be intermixed with other ſmall annual plants in large borders, where they will make a pretty appearance.

The juice of theſe plants is of a yellow colour, reſembling that of Celandine, and is affirmed by ſome eminent phyſicians to have the ſame effect as opium.

HYPERICUM. Tourn. Inſt. R. H. 254. tab. 131. Lin. Gen. Plant. 808. St. Johnſwort; in French, *Millepertuis*.

The Characters are,

The flower hath a permanent empalement, divided into five oval concave ſegments; it hath five oblong oval petals which ſpread open, and a great number of hairy ſtamina, which are joined at their baſe in three or five diſtinct bodies, terminated by ſmall ſummits. It hath in the center a roundiſh germen, ſupporting one, three, or five ſtyles, the ſame length of the ſtamina, crowned by ſingle ſtigmas. The germen afterward becomes a roundiſh capſule, having the ſame number of cells as there are ſtyles in the flower, which are filled with oblong ſeeds.

This genus of plants is ranged in the third ſection of Linnæus's eighteenth claſs, intitled Polyadelphia Polygynia, which contains the plants whoſe flowers have many ſtamina joined in diſtinct bodies, and ſeveral ſtyles.

The Species are,

1. Hypericum (*Perfoliatum*) floribus trigynis, caule ancipiti, foliis obtuſis pellucido-punctatis. Hort. Cliff. 383. *St. Johnſwort with three ſtyles to the flower, and obtuſe leaves having pellucid punctures.* Hypericum vulgare. C. B. P. 279. *Common St. Johnſwort.*
2. Hypericum (*Quadrangulum*) floribus trigynis, caule quadrato herbaceo. Hort. Cliff. 380. *St. Johnſwort with three ſtyles to the flowers, and a ſquare herbaceous ſtalk.* Hypericum Aſcyron dictum, caule quadrangulo. J. B. 3. p. 382. *St. Johnſwort with a ſquare ſtalk, commonly called St. Peterſwort.*
3. Hypericum (*Hircinum*) floribus trigynis, ſtaminibus corollâ longioribus, caule fruticoſo ancipiti. Hort. Cliff. 331. *St. Johnſwort with three ſtyles to the flower, ſtamina longer than the petals, and a ſhrubby ſtalk with two ſides.* Hypericum fœtidum fruteſcens. Tourn. 255. *Stinking ſhrubby St. Johnſwort.*
4. Hypericum floribus trigynis, calycibus obtuſis, ſtaminibus corollâ longioribus caule fruticoſo. Hort. Cliff. 381. *St. Johnſwort with three ſtyles to the flower, obtuſe empalements, ſtamina longer than the petals, and a ſhrubby ſtalk.* Hypericum fruteſcens Canarienſe multiflorum. Hort. Amſt. 2. p. 135. *Shrubby St. Johnſwort from the Canaries, having many flowers.*
5. Hypericum (*Olympicum*) floribus trigynis, calycibus acutis, ſtaminibus corollâ brevioribus, caule fruticoſo. Hort. Cliff. 380. *St. Johnſwort with three ſtyles to the flower, acute empalements, ſtamina ſhorter than the petals, and a ſhrubby ſtalk.* Hypericum Orientale, flore magno. T. Cor. 19. *Eaſtern St. Johnſwort, with a large flower.*
6. Hypericum (*Inodorum*) floribus trigynis, calycibus obtuſis, ſtaminibus corollâ longioribus, capſulis coloratis, caule fruticoſo. *St. Johnſwort with three ſtyles to the flower, obtuſe empalements, ſtamina longer than the petals, coloured ſeed-veſſels, and a ſhrubby ſtalk.* Hypericum Orientale, fœtido ſimile, ſed inodorum. Tourn. Cor. 19. *Eaſtern St. Johnſwort, like the ſtinking kind, but without ſmell.*
7. Hypericum (*Aſcyron*) floribus pentagynis, caule tetragono herbaceo ſimplici, foliis lævibus integerrimis. Hort. Upſal. 236. *St. Johnſwort with five ſtyles to the flower, a ſquare, ſingle, herbaceous ſtalk, and ſmooth entire leaves.* Aſcyrum magno flore. C. B. P. 280. *Tutſan with a large flower.*
8. Hypericum (*Balearicum*) floribus pentagynis, caule fruticoſo, foliis ramiſque cicatriſatis. Lin. Sp. Plant. 783. *St. Johnſwort with five ſtyles to the flower, a ſhrubby ſtalk, and ſcarified leaves and branches.* Aſcyron Balearicum, fruteſcens, maximo flore luteo, foliis minoribus, ſubtus verrucoſis ſalvad. Boerh. Ind. alt. 1. 242. *Shrubby Balearick St. Peterſwort with a large yellow flower, and ſmaller leaves warted on their under ſide.*
9. Hypericum (*Androſæmum*) floribus trigynis pericarpiis baccatis, caule fruticoſo ancipiti. Hort. Upſal. 237. *St. Johnſwort with three ſtyles to the flower, a fleſhy ſeed-veſſel, and a ſhrubby ſtalk with two ſides.* Androſæmum maximum fruteſcens. C. B. P. 280. *Common Tutſan, or Park-leaves.*
10. Hypericum (*Bartramium*) floribus pentagynis calycibus obtuſis, ſtaminibus corollâ æquantibus, caule erecto herbaceo. *St. Johnſwort with five ſtyles to the flower, obtuſe empalements, ſtamina equalling the petals, and an erect herbaceeus ſtalk.*
11. Hypericum (*Monogynum*) floribus monogynis, ſtaminibus corollâ longioribus, calycibus coloratis, caule fruticoſo. *St. Johnſwort with one ſtyle to the flowers, ſtamina longer than the petals, coloured empalements, and a ſhrubby ſtalk.*

There are ſome other ſpecies of this genus, which are preſerved in botanic gardens for the ſake of variety, but as they are ſeldom admitted into other gardens, I have not enumerated them here, leſt the work ſhould ſwell too large.

The firſt and ſecond ſorts are both very common plants, growing in the fields in moſt parts of England; the firſt is uſed in medicine, but the ſecond is of no uſe: theſe are rarely propagated in gardens, but I chuſe to mention them, in order to introduce the other ſorts, which deſerve a place in every good garden.

The firſt ſort hath a perennial root, from which ariſe ſeveral round ſtalks a foot and a half high, dividing into many ſmall branches, which are garniſhed at each joint with two ſmall oblong leaves, ſtanding oppoſite, without foot-ſtalks; the branches alſo come out oppoſite. The leaves have many pellucid ſpots in them, which appear like ſo many holes when held up againſt the light. The flowers are numerous on the tops of the branches, ſtanding on ſlender foot-ſtalks; they are compoſed of five oval petals, of a yellow colour, with a great number of ſtamina, not quite ſo long as the petals, terminated by roundiſh ſummits. In the center is ſituated a roundiſh germen, ſupporting three ſtyles, crowned by ſingle ſtigmas. The germen afterward becomes an oblong angular capſule, with three cells, filled with ſmall brown ſeeds. It flowers in June and July, and the ſeeds ripen in autumn. The root is perennial, ſo will continue many years; and if the ſeeds are permitted to ſcatter, the plants will come up in too great plenty, ſo as to be very troubleſome weeds. The leaves and flowers of this are uſed in medicine; it is eſteemed an excellent vulnerary plant, and of great ſervice in wounds, bruiſes, and contuſions: there is a compound oil made from this plant, which is of great uſe in the foregoing accidents. From the ſtamina of the flower is expreſſed a red juice, which is ſometimes uſed in colouring, but fades very ſoon.

The ſecond ſort hath ſquare ſtalks, which riſe about the ſame height with the firſt, but do not branch ſo much. The leaves are ſhorter and broader than thoſe of the firſt, and have no pellucid ſpots. The flowers ſit upon ſhort foot-ſtalks at the end of the branches, which are ſhaped like thoſe of the other. This flowers and ſeeds at the ſame time with the other, and will propagate in as great plenty if the ſeeds are permitted to ſcatter.

The third ſort grows naturally in Sicily, Spain, and Portugal; this riſes with ſhrubby ſtalks about three feet high, ſending out ſmall branches at each joint oppoſite, which are garniſhed with oblong oval leaves, placed by pairs, ſitting cloſe to the ſtalks, which have a rank ſmell like a goat. The flowers are produced in cluſters at the end of the branches; they are compoſed of five oval yellow petals, with a great number of ſtamina which are longer than the petals, and three ſtyles which are longer than the ſtamina. The germen which ſupports theſe, afterward becomes an oval capſule with three cells, filled with ſmall ſeeds. It flowers in June, July, and Auguſt, and the ſeeds ripen in autumn.

The fourth ſort grows naturally in the Canary Iſlands, ſo was formerly preſerved in green-houſes during the winter ſeaſon, but is found to be hardy enough to reſiſt the greateſt cold of this country, ſo is now cultivated in the nurſeries as a flowering ſhrub; this riſes with a ſhrubby ſtalk ſix or ſeven feet high, dividing into branches upward, which are garniſhed with oblong leaves, ſet by pairs cloſe to the branches. The leaves of this have alſo a ſtrong odour, but not quite ſo bad as the former. The flowers are produced at the end of the ſtalks in cluſters, and are very like thoſe of the former ſort, having a great number of ſtamina which are longer than the petals; this flowers at the ſame time with the former, and perfects its ſeeds in autumn. Both theſe plants have a very ſtrong odour like that of a goat; ſo that where the plants grow in large quantities, the ſcent is carried by the wind to a great diſtance; or, if the leaves are handled, they emit the ſame odour.

Theſe two ſorts are propagated by ſuckers, which are plentifully ſent forth from the old plants. The beſt ſeaſon for taking off the ſuckers is in March, juſt before they begin to ſhoot; they ſhould be planted in a light dry ſoil, in which they will endure the ſevereſt cold of our climate very well. They may alſo be propagated by cuttings, which ſhould be planted at the ſame ſeaſon; or by ſeeds, which muſt be ſown in Auguſt or September, which is as ſoon as they are ripe; for if they are kept till ſpring, few of them will grow; but as they multiply ſo faſt by ſuckers, the other methods of propagating them are ſeldom practiſed in England.

The fifth ſort grows naturally on Mount Olympus, where it was diſcovered by Sir George Wheeler, who ſent the ſeeds to the Oxford garden; this riſes with many upright ligneous ſtalks about a foot high, garniſhed with ſmall ſpear-ſhaped leaves, ſitting cloſe to the ſtalks oppoſite. The flowers are produced at the the top of the ſtalks, three or four together; they are compoſed of five oblong petals, of a bright yellow colour, with a great number of ſtamina, which are of unequal lengths, ſome being longer, and others ſhorter than the petals, terminated by ſmall roundiſh ſummits. In the center is ſituated an oval germen, ſupporting three ſlender ſtyles, which are longer than the ſtamina. The germen afterward becomes an oval capſule with three cells, filled with ſmall ſeeds. This flowers in July and Auguſt, and in warm ſeaſons ripens its ſeeds in autumn.

This plant is uſually propagated by parting of the roots, becauſe the ſeeds ſeldom ripen in this country; the beſt time for doing of this is in September, that the plants may have time to get root before winter; this will live in the open air, if it is planted in a warm ſituation and a dry ſoil, but it will be proper to keep a plant or two in pots, to be ſheltered under a frame in winter, leſt in very ſevere winters, thoſe in the open air ſhould be deſtroyed. If this is propagated by ſeeds, they ſhould be ſown ſoon after they are ripe, in pots filled with light earth, and placed under a frame in the winter, to ſhelter them from froſt, and in the ſpring the plants will appear; when theſe are fit to remove, ſome of them may be planted in a warm border, and others in pots, and treated in the ſame way as the old plants.

The ſixth ſort riſes with a ſhrubby ſtalk ſeven or eight feet high, with a reddiſh bark, and ſends out many ſmaller branches, garniſhed with oval heart-ſhaped leaves, whoſe baſe ſits cloſe to the ſtalks; they are placed oppoſite. The flowers are produced at the end of the ſtalks in cluſters; they are ſmaller than thoſe of the third ſort, and have obtuſe empalements. The ſtamina are longer than the petals, and are of a deeper colour. The flowers are ſucceeded by conical capſules of a purpliſh red colour, having three cells, filled with ſmall ſeeds. It flowers in May, June, and July, and the ſeeds ripen in autumn. This is now propagated in the nurſeries as a flowering ſhrub, and may be treated in the ſame way as the third and fourth ſorts.

The ſeventh ſort was firſt brought to England from Conſtantinople, but has long been very common in the Engliſh gardens, for the roots ſpread and increaſe very faſt, where it is permitted to ſtand long unremoved. The ſtalks of this are ſlender, and incline downward; they are garniſhed with oval, ſpear-ſhaped, ſmooth leaves, placed by pairs, ſitting cloſe to the ſtalks. The flowers are produced at the end of the ſtalks; theſe are very large, and of a bright yellow colour, with a great number of ſtamina, which ſtand out beyond the petals; there are five ſtyles in each flower, which are of the ſame length with the ſtamina. The flowers are ſucceeded by pyramidal ſeed-veſſels with five cells, containing many ſmall ſeeds. It flowers in June and July.

This plant is eaſily propagated by parting of the root; the beſt time for this is in October, that the plants may be well eſtabliſhed before the drought of ſpring, otherwiſe they will not produce many flowers. As this will grow under trees, ſo it is a very proper plant to place under ſhrubs and trees to cover the ground, where they will make a good appearance during the ſeaſon of their flowering.

The eighth ſort grows naturally in the iſland of Minorca, from whence the ſeeds were ſent to England, by Mr. Salvador, an apothecary at Barcelona, in the year 1718; this riſes with a ſlender ſhrubby ſtalk in this country about two feet high, but in its native ſoil riſes ſeven or eight feet high, ſending out ſeveral weak branches of a reddiſh colour, which are marked where the leaves have fallen off with a cicatrice. The leaves are ſmall, oval, and waved on their edges, having ſeveral ſmall protuberances on their under ſide, ſitting cloſe to the ſtalks, half embracing them with their baſe. The flowers are produced at the top of the ſtalks; they are large, of a bright yellow colour, with a great number of ſtamina, which are a little ſhorter than the petals; theſe flowers have five ſtyles, and are ſucceeded by pyramidal capſules with five cells, which have a ſtrong ſmell of turpentine, and are filled with ſmall brown ſeeds: this plant has a ſucceſſion of flowers great part of the year, which renders it valuable; it is too tender to live through the winter in the open air in England, but requires no artificial heat: if the plants are placed in a dry airy glaſs-caſe in winter, where they may be protected from froſt, and enjoy a good ſhare of freſh air in mild weather, they will thrive better than in a warmer ſituation; but they muſt by no means be placed in a damp air, for their ſhoots ſoon grow mouldy and decay with damp, nor ſhould the plants have much water during the winter; but in ſummer they ſhould be expoſed in the open air, and in warm weather they ſhould be gently watered three times a week; they ſhould have a looſe ſandy ſoil, not over rich. This is propagated by cuttings, which ſhould be planted in June, in pots filled with light earth, and plunged into a very moderate hot-bed, whoſe heat is declining, ſhading them from the ſun in the heat of the day, and now and then refreſhing them with water; theſe cuttings, ſo managed, will put out roots in ſix or ſeven weeks, when they ſhould be carefully taken up, and each planted into a ſeparate ſmall pot, placing them in the ſhade till they have taken new root; then they may be removed to a ſheltered ſituation, where they may remain till the froſt comes, when they ſhould be removed into ſhelter.

If theſe are propagated by ſeeds, they ſhould be ſown in autumn, in the ſame way as is before directed for the fifth ſort, and the plants treated in the ſame manners as thoſe raiſed from cuttings.

The ninth ſort is the common Tutſan, or Park-leaves, which is ſometimes uſed in medicine. It grows naturally in woods in ſeveral parts of England, ſo is not often admitted into gardens; this hath a ſhrubby ſtalk, which riſes two feet high, ſending out ſome ſmall branches toward the top; theſe, and alſo the ſtalks, are garniſhed with oval heart-ſhaped leaves, ſitting cloſe to them with their baſe, they are placed by pairs at every joint. The flowers are produced in ſmall cluſters at the end of the ſtalk; theſe are yellow, but ſmaller than either of the ſorts here mentioned; they have many long ſtamina, which ſtand out beyond the flower, and three ſtyles. The germen afterward turns to a roundiſh fruit, covered with a moiſt pulp, which, when ripe, is black. The capſule has three cells, containing ſmall ſeeds. It flowers in June, and the ſeeds are ripe in autumn. It hath a perennial root, and may be propagated by parting it in autumn; it loves ſhade and a ſtrong ſoil.

The tenth ſort grows naturally in North America; this riſes with an upright herbaceous ſtalk three feet and a half high, ſending out ſeveral ſmall branches upward, which come out oppoſite, and are garniſhed with oblong leaves placed oppoſite, which half embrace the ſtalk with their baſe. At the end of each ſtalk is produced one pretty large yellow flower, with an obtuſe empalement, having many ſtamina, which are equal in length with the petals, and five ſtyles which are ſo cloſely joined as to appear but one. The ſtigmas are reflexed, which denote their number. This ſort ſeldom ripens ſeeds here, ſo is propagated by parting the roots. The beſt time for this is in autumn; it ſhould have a light ſoil and an open ſituation. The flowers appear the latter end of July, and in Auguſt.

The eleventh ſort grows naturally in China, from whence the ſeeds were brought to the Right Hon. the Earl of Northumberland, and the plants were raiſed in his Lordſhip's curious garden at Stanwick, and by his Lordſhip's generoſity the Chelſea garden was furniſhed with this plant.

The root of this plant is compoſed of many ligneous fibres, which ſtrike deep in the ground; from which ariſe ſeveral ſhrubby ſtalks near two feet high, covered with a purpliſh bark, and garniſhed with ſtiff ſmooth leaves about two inches long, and a quarter of an inch broad, placed by pairs, ſitting cloſe to the ſtalk; they are of a lucid green on their upper ſide, and gray on their under, having many tranſverſe veins running from the midrib to the border. The flowers are produced at the top of the ſtalks, growing in ſmall cluſters, each ſtanding upon a ſhort diſtinct foot-ſtalk; theſe have an empalement of one leaf, divided into five obtuſe ſegments almoſt to the bottom, which is of a deep purple colour. The flower is compoſed of five large obtuſe petals, of a bright yellow colour; theſe are concave, and in the center is ſituated an oval germen ſupporting a ſingle ſtyle, crowned by five ſlender ſtigmas, which bend on one ſide; the ſtyle is attended by a great number of ſtamina which are longer than the petals, and terminated by roundiſh ſummits.

This plant continues in flower great part of the year, which renders it the more valuable; and if it is planted in a very warm ſituation, it will live in the open air; but thoſe plants which ſtand abroad will not flower in winter, as thoſe do which are removed into ſhelter in autumn.

It may be propagated by ſlips from the root, or by laying down of the branches; if by ſlips, they ſhould be planted in the ſpring on a moderate hot-bed, which will forward their putting out new roots; the layers ſhould alſo be laid down at the ſame time, which will have taken root by autumn, when they may be tranſplanted into pots, and ſheltered under a frame in winter; and in the ſpring, part of theſe may be planted in a warm border, and the others continued in pots to be ſcreened in winter, leſt thoſe in the open air ſhould be killed.

HYPERICUM FRUTEX. See Spiræa.

HYPOCHÆRIS, a ſort of Hawkweed, of which there are two or three ſpecies, which grow naturally in England; the others are ſeldom admitted into gardens, therefore I ſhall not enumerate them.

HYPOPHYLLOSPERMOUS PLANTS [of ὑπὸ, under, φύλλον, a leaf, and σπέρμα, ſeed,] are ſuch plants as bear their ſeeds on the backſides of their leaves.

HYSSOPUS. Tourn. Inſt. R. H. 200. tab. 95. Lin. Gen. Plant. 628. [takes its name from the Hebrew word אזוב, in which language Hyſſop ſignifies a holy herb, or for purging or cleanſing ſacred places, as it is ſaid in the Pſalms, Purge me with Hyſſop. But what plant the Hyſſop of the antients was, is not known, but that it ſeems to have been a low plant, becauſe Solomon is ſaid to have deſcribed the plants from the Cedar to the Hyſſop.] Hyſſop; in French, *Hiſope.*

The Characters are,

The empalement of the flower is oblong, cylindrical, ſtreaked, and permanent. It is of one leaf, cut into five acute parts at the top. The flower is of one petal, of the grinning kind, with a narrow cylindrical tube the length of the empalement. The chaps are inclining. The upper lip is ſhort, plain, roundiſh, erect, and indented at the top. The under lip is trifid, the two ſide ſegments being ſhorter than the middle one, which is crenated. It hath four ſtamina, which ſtand apart; two of them are longer than the petal, the other two are ſhorter, terminated by ſingle ſummits. It hath four germen, with a ſingle ſtyle ſituated

ſituated under the upper lip, crowned by a bifid ſtigma. The germen afterward becomes ſo many oval ſeeds ſitting in the empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's fourteenth claſs, intitled Didynamia Gymnoſpermia, which contains thoſe plants whoſe flowers have two long and two ſhort ſtamina, and are ſucceeded by naked ſeeds in the empalement.

The Species are,

1. Hyssopus (*Officinalis*) ſpicis fecundis. Hort. Cliff. 304. *Hyſſop with fruitful ſpikes.* Hyſſopus officinarum cœrulea ſeu ſpicata. C. B. P. 217. *Hyſſop of the ſhops with blue ſpikes, or the common Hyſſop.*
2. Hyssopus (*Rubra*) ſpicis brevioribus, verticillis compactis. *Hyſſop with ſhorter ſpikes, and whorls more compact.* Hyſſopus rubro flore. C. B. P. 217. *Hyſſop with a red flower.*
3. Hyssopus (*Altiſſimis*) ſpicis longiſſimis verticillis diſtantibus. *Hyſſop with the longeſt ſpikes, and whorls at a greater diſtance.* Hyſſopus verticillis florum rarioribus. Houſt. *Hyſſop with the whorls of flowers thinly ranged.*
4. Hyssopus (*Nepetoides*) caule acuto quadrangulo. Hort. Upſal. 163. *Hyſſop with an acute ſquare ſtalk.* Sideritis Canadenſis altiſſima, ſcrophulariæ folio, flore flaveſcente. Tourn. Inſt. 192. *Talleſt Canada Ironwort, with a Figwort leaf and a yellowiſh flower.*
5. Hyssopus (*Lophanthus*) corollis ſubreſupinatis ſtaminibus corollâ brevioribus. Hort. Upſal. 162. *Hyſſop with tranſverſe petals, and the lower ſtamina ſhorter than the petal.* Nepeta floribus obliquis. Dill. *Catmint with oblique flowers.*

The firſt ſort, which is the only one cultivated for uſe, grows a foot and a half high. The ſtalks are firſt ſquare, but afterward become round; their lower parts are garniſhed with ſmall ſpear-ſhaped leaves placed oppoſite, without foot-ſtalks, and ſeven or eight very narrow erect leaves (or bractæa) riſing from the ſame joint. The upper part of the ſtalk is garniſhed with whorls of flowers, the lower ones ſtanding half an inch apart, but the upper are almoſt joined together. The upper lip of the flower is indented at the top, and the under is cut into three parts, the middle being deeply indented at the point. There are four ſtamina in each flower, which ſpread at a diſtance from each other; the two upper are the ſhorteſt, which are ſituated on each ſide the upper lip; the two longer ſtand cloſe to the two ſide ſegments, and are terminated by twin ſummits. At the bottom of the tube are ſituated four naked germen, ſupporting a ſlender ſtyle, ſitting cloſe to the upper lip, crowned by a bifid ſtigma; theſe germen afterward become four oblong black ſeeds, ſitting in the empalement. The whole plant has a ſtrong aromatic ſcent. It flowers in July and Auguſt, and the ſeeds ripen in September, but the roots will abide many years; it grows naturally in the Levant. There is a variety of this with white flowers, but doth not differ from the blue in any other particular.

The ſecond ſort doth not grow ſo tall as the firſt; the ſtalks branch more, and the ſpikes of flowers are much ſhorter than thoſe of the firſt. The whorls are cloſer together, and have long narrow leaves ſituated under each. The flowers are of a fine red colour, and appear at the ſame time with the former. This ſort is not quite ſo hardy as the common, for in 1739 the plants were all deſtroyed by the cold; this is certainly a diſtinct ſpecies, for I cultivated it from ſeeds twenty years, and never obſerved it to vary.

The third ſort grows much taller than either of the other. The leaves are narrower, the whorls of flowers are farther aſunder, the ſpikes of flowers are much longer, the flowers are larger, and of a deeper blue than thoſe of the common ſort, and the plant hath not ſo ſtrong an odour. It flowers at the ſame time as the firſt.

Theſe three ſorts of Hyſſop are propagated either by ſeeds or cuttings; if by the ſeeds, they muſt be ſown in March, upon a bed of light ſandy ſoil; and when the plants come up, they ſhould be tranſplanted out to the places where they are to remain, placing them at leaſt a foot aſunder each way; but if they are deſigned to abide in thoſe places for a long time, two feet diſtance will be ſmall enough, for they grow pretty large, eſpecially if they are not frequently cut, to keep them within compaſs; they thrive beſt upon a poor dry ſoil, in which ſituation they will endure the cold of our climate better than when they are planted on a richer ſoil. If you would propagate them by cuttings, they ſhould be planted in April or May, in a border where they may be defended from the violent heat of the ſun; and being frequently watered, they will take root in about two months; after which, they may be tranſplanted where they are to continue, managing them as was before directed for the ſeedling plants.

The firſt ſort was formerly more cultivated than at preſent in England, that being the ſort commonly uſed in medicine. The other ſpecies are preſerved in curious gardens for their variety, but they are ſeldom cultivated for uſe.

They are very hardy plants, which will endure the cold of our winters in the open air, provided they are planted in a dry undunged ſoil; for when they are planted in a rich ſoil, they grow very luxuriant in ſummer, and are leſs able to reſiſt the cold in winter; ſo that when any of theſe plants grow out of the joints of old walls, (as they frequently do) they will reſiſt the moſt ſevere froſt, and will be much more aromatic than thoſe which grow in a rich ſoil.

The fourth ſort grows naturally in North America; this hath a perennial root and an annual ſtalk, which decays in autumn. It riſes with an upright ſquare ſtalk near four feet high, garniſhed with oblique heart-ſhaped leaves, which are ſawed on their edges, and end in acute points; they are placed oppoſite on ſhort foot-ſtalks. The flowers grow in cloſe thick ſpikes four or five inches long, at the top of the ſtalks. The upper lip is divided into two roundiſh ſegments, the lower one is divided into three, the two ſide ſegments ſtanding erect, and the middle one is reflexed, and acutely ſawed at the end. The two upper ſtamina, which are ſituated on each ſide the upper lip are the longeſt, the other two ſhorter join the two ſide ſegments of the lower lip; they are terminated by ſmall ſummits. The germen are ſituated at the bottom of the tube, having a ſlender ſtyle under the upper lip, crowned by a bifid ſtigma. The germen afterward becomes four oblong brown ſeeds, ſitting in the tubulous empalement. This ſort flowers in July, and the ſeeds ripen in September.

There is a variety of this ſort with purple ſtalks and purpliſh flowers. The leaves ſtand upon longer foot-ſtalks, and the ſpikes of flowers are thicker, but I cannot ſay if it is a diſtinct ſpecies or only a variety. It grows naturally in the ſame country with the other. It is titled, Betonica maxima, folio ſcrophulariæ, floribus incarnatis, by Herman. Par. Bat. 106.

The fifth ſort grows naturally in Siberia. The ſeeds of this were ſent me from the Imperial garden at Peterſburgh, by the title of Lophanthus, and afterward I received ſome from Holland, which were titled, Nepeta floribus obliquis. Dill. This is a perennial plant with a ſtrong fibrous root, ſending out many ſquare ſtalks, which divide into ſmaller branches, garniſhed with oblong leaves, crenated on their edges, ſet on by pairs. The flowers are produced at each joint in ſmall cluſters, two foot-ſtalks ariſing from the baſe of the leaves, about half an inch long, both inclining to one ſide of the ſtalk; each of theſe foot-ſtalks divide again into two ſmaller, and theſe do each ſupport a cluſter of four or five flowers, which have ſwelling tubulous empalements, cut into five acute ſegments at the top. The tube of the petal is longer than the empalement. The lips of the flower are oblique to it, being ſituated horizontally. The two upper ſtamina and the ſtyle ſtand out beyond the petal, but the other are ſhorter. The flowers are blue, and appear in June and July, and the ſeeds ripen in September.

Both theſe ſorts are very hardy, and may be eaſily propagated by ſeeds, which ſhould be ſown in autumn; for thoſe ſown in the ſpring, often lie a year in the ground before they vegetate; when the plants come up, they muſt be kept clean from weeds, and thinned where they are too cloſe. The following autumn they ſhould be tranſplanted where they are to remain, and the plants will flower in ſummer, and produce ſeeds, but the roots will abide ſome years.

It hath been a diſpute amongſt modern writers, whether the Hyſſop now commonly known is the ſame which is mentioned in ſcripture; about which there is great room to doubt, there being very little grounds to aſcertain that plant, though it is moſt generally thought to be the Winter Savory, which plant is now in great requeſt amongſt the inhabitants of the eaſtern countries, for outward waſhings or purification.

J.

JACEA. See Centaurea.

JACOBÆA. See Senecio and Othonna.

JACQUINIA. Lin. Gen. 254.

The Characters are,

The empalement of the flower is compoſed of five roundiſh concave leaves, and is permanent. The flower has one bell-ſhaped petal, which is bellied, cut into ten ſegments. It hath five awl-ſhaped ſtamina ariſing from the receptacle, terminated by halbert-ſhaped ſummits, and an oval germen ſupporting a ſtyle the length of the ſtamina, crowned by a headed ſtigma. The germen afterward becomes a roundiſh berry with one cell, containing one ſeed.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, the flowers having five ſtamina and one ſtyle.

The Species are,

1. Jacquinia (*Ruſcifolia*) foliis lanceolatis acuminatis. Jacq. Amer. 15. Lin. Sp. 271. *Jacquinia with ſpear-ſhaped acute-pointed leaves.* Fruticulus foliis ruſci ſtellatis. Hort. Elth.
2. Jacquinia (*Armillaris*) foliis obtuſis cum acumine. Jacq. Amer. 15. Lin. Sp. 272. *Jacquinia with blunt leaves ending in acute points.* Chryſophyllum Barbaſco. Lœfl. it. 204.
3. Jacquinia (*Linearis*) foliis linearibus acuminatis. Jacq. Amer. 15. Lin. Sp. 272. *Jacquinia with linear ſharp-pointed leaves.*

The firſt ſort grows naturally in the iſland of Cuba, and in ſome other warm parts of America; it riſes with a ſhrubby ſtalk about a foot high, which is ligneous at the bottom, and about the ſize of a ſwan's quill, covered with a dark brown bark, ſending out a few ſlender branches, garniſhed at intervals with hand-ſhaped ſtiff leaves, placed in whorls round them; theſe are ſtiff like thoſe of Butcher's Broom, ending with ſharp points, of a deep green on their upper ſide, but pale on their under; the flowers are (according to Plumier's figure) produced from between the leaves on the top of the branches; but having ſeen no flowers in England, ſo I can give no farther account of them.

The ſecond ſort grows naturally at Carthagena, Martinico, and other parts of South America, where it riſes with a ſhrubby ſtalk four or five feet high, dividing toward the top into four branches, which are ſituated in whorls round the principal ſtalk, garniſhed with oblong blunt leaves, placed alſo in whorls, having a ſhort ſlender apex. The flowers are produced in a racemus on the end of the branches, each containing five or ſix white flowers of a thick conſiſtence, which have a ſcent like Jaſmine flowers, which they retain after they decay, ſo are worn by the ladies of thoſe countries for ornament.

The third ſort grows naturally on the borders of the ſea, in the iſland of Dominica; this is an under-ſhrub, of a very low growth, rarely riſing about two feet high, dividing into ſeveral branches, garniſhed with linear ſtiff leaves, ending with a thorn; theſe are placed in whorls round the branches, and from the middle of the whorls come out the foot-ſtalks of the flowers, each being terminated by one ſmall white flower without ſcent.

As theſe plants are natives of hot countries, ſo they will not live in England, unleſs they are placed in a warm ſtove, and treated in the manner directed for other plants from the ſame countries, giving them little water in winter, and in warm weather plenty of freſh air. They are raiſed from ſeeds, when they can be procured from the countries where they naturally grow; which muſt be ſown on a hot-bed, and may afterward be propagated by cuttings, though it is with difficulty they take root.

JALAPA. See Mirabilis.

JASIONE. Lin. Gen. Plant. 896. This is the Rapunculus ſcabioſæ capitulo cœruleo. C. B. P. 22. Rampions with Scabious heads. This plant grows naturally on ſterile ground in moſt parts of England, and is rarely admitted into gardens.

JASMINOIDES. See Cestrum and Lycium.

JASMINUM. Tourn. Inſt. R. H. 597. tab. 368. Lin. Gen. Plant. 17. [This name is Arabic.] The Jaſmine, or Jeſſamine-tree; in French, *Jaſmin.*

The Characters are,

The flower hath a tubulous empalement of one leaf, which is permanent, and cut into five ſegments at the brim, which are erect. The flower is of one petal, having a long cylindrical tube, cut into five ſegments at the top, which ſpread open. It hath two ſhort ſtamina, which are terminated by ſmall ſummits, and are ſituated within the tube of the petal. In the center is ſituated a roundiſh germen, ſupporting a ſlender ſtyle, crowned by a bifid ſtigma. The germen afterward turns to an oval berry, with a ſoft ſkin incloſing two ſeeds, which are flat on thoſe ſides which join, and convex on the other.

This genus of plants is ranged in the firſt ſection of Linnæus's ſecond claſs, intitled Diandria Monogynia, in which he ranges thoſe plants whoſe flowers have two ſtamina and one ſtyle.

The Species are,

1. Jasminum (*Officinale*) foliis oppoſitis pinnatis, foliolis acuminatis. *Jaſmine with winged leaves placed oppoſite,*

poſite, whoſe lobes end in acute points. Jaſminum vulgatius, flore albo. C. B. P. 397. *The common white Jaſmine.*

2. Jasminum (*Humile*) foliis alternis ternatis ſimplicibuſque, ramis angulatis. Hort. Upſal. 5. *Jaſmine with trifoliate winged leaves placed alternate, and angular branches.* Jaſminum humile luteum. C. B. P. 397. *Dwarf yellow Jaſmine, commonly called the Italian yellow Jaſmine.*
3. Jasminum (*Fruticans*) foliis alternis ternatis ſimplicibuſque, ramis angulatis. Hort. Cliff. 5. *Jaſmine with trifoliate ſingle leaves placed alternate, and angular branches.* Jaſminum luteum, vulgò dictum bacciferum. C. B. P. 398. *The common yellow Jaſmine.*
4. Jasminum (*Grandiflorum*) foliis oppoſitis pinnatis, foliolis brevioribus obtuſis. *Jaſmine with winged leaves placed oppoſite, whoſe lobes are ſhorter and obtuſe.* Jaſminum humilis, magno flore. C. B. P. 398. *The Spaniſh white, or Catalonian Jaſmine with a larger flower.*
5. Jasminum (*Odoratiſſimum*) foliis alternis ternatis, foliolis ovatis, ramis teretibus. *Jaſmine with trifoliate leaves placed alternate, whoſe lobes are oval, and taper branches.* Jaſminum Indicum flavum odoratiſſimum. Fer. Flor. *The ſweet-ſcented yellow Indian Jaſmine.*
6. Jasminum (*Azoricum*) foliis oppoſitis ternatis, foliolis cordato-acuminatis. *Jaſmine with trifoliate leaves placed oppoſite, whoſe lobes are heart-ſhaped and pointed.* Jaſminum Azoricum trifoliatum, flore albo, odoratiſſimum. Hort. Amſt. *The three-leaved Azorian Jaſmine, with very ſweet white flowers, commonly called the Ivy-leaved Jaſmine.*
7. Jasminum (*Capenſe*) foliis lanceolatis oppoſitis integerrimis, floribus triandris. *Jaſmine with ſpear-ſhaped entire leaves placed oppoſite, and flowers with three ſtamina.*

The firſt ſort is the common white Jaſmine, which is a plant ſo generally known as to need no deſcription. This grows naturally at Malabar, and in ſeveral parts of India, yet has been long inured to our climate, ſo as to thrive and flower extremely well, but never produces any fruit in England; this hath weak trailing branches, ſo requires the aſſiſtance of a wall or pale to ſupport them. It is eaſily propagated by laying down the branches, which will take root in one year, and may then be cut from the old plant, and planted where they are deſigned to remain: it may alſo be propagated by cuttings, which ſhould be planted early in the autumn, and if the winter ſhould prove ſevere, the ſurface of the ground between them ſhould be covered with tan, ſea-coal aſhes, or ſaw-duſt, which will prevent the froſt from penetrating deep into the ground, and thereby preſerve the cuttings; or where theſe are wanting, ſome Peas-haulm, or other light covering ſhould be laid over the cuttings in hard froſt; but theſe muſt be removed when the weather is mild, for they will keep off the air and occaſion damps, which often deſtroy them.

When theſe plants are removed, they ſhould be planted where they are deſigned to be continued, which ſhould be either againſt ſome wall, pale, or other fence, where the flexible branches may be ſupported; for although it is ſometimes planted as a ſtandard, and formed into a head, yet it will be very difficult to keep it in any handſome order; or if you do, you muſt cut off all the flowering branches; for the flowers are always produced at the extremity of the ſame year's ſhoots, which, if ſhortened before the flowers are blown, will entirely deprive the trees of flowers. Theſe plants ſhould be permitted to grow rude in the ſummer, for the reaſon before given; nor ſhould you prune and nail them until the middle or latter end of March, when the froſty weather is paſt; for if it ſhould prove ſharp froſty weather after their rude branches are pruned off, and the ſtrong ones are expoſed thereto, they are very often deſtroyed; and this plant being very backward in ſhooting, there will be no danger of hurting them by late pruning.

There are two varieties of this with variegated leaves, one with white, and the other yellow ſtripes, but the latter is the moſt common: theſe are propagated by budding them on the plain Jaſmine, and it often happens, that the buds do not take, but yet they have communicated their gilded miaſma to the plants; ſo that in a ſhort time after, many of the branches both above and below the places where the buds have been inſerted have been thoroughly tinctured; and the following year I have often found very diſtant branches, which had no other communication with thoſe which were budded than by the root, have been as compleatly tinged as any of the nearer branches, ſo that the juices muſt have deſcended into the root.

The two ſtriped ſorts ſhould be planted in a warm ſituation, eſpecially the white ſtriped; for they are much more tender than the plain, and are very ſubject to be deſtroyed by great froſts, if they are expoſed thereto; therefore the white ſtriped ſhould be planted to a ſouth or ſouth-weſt aſpect, and in very ſevere winters their branches ſhould be covered with mats or ſtraw, to prevent their being killed: the yellow ſtriped is not ſo tender, ſo may be planted againſt walls to eaſt or weſt aſpects; but theſe plants with variegated leaves, are not ſo much in eſteem as formerly.

The ſecond ſort is frequently called Italian yellow Jaſmine by the gardeners, the plants being annually brought from thence by thoſe who come over with Orange-trees. Theſe plants are generally grafted upon the common yellow Jaſmine ſtocks, ſo that if the graft decays, the plants are of no value. This ſort is ſomewhat tenderer than the common, yet it will endure the cold of our ordinary winters, if it is planted in a warm ſituation. The flowers of this kind are generally larger than thoſe of the common yellow ſort, but have very little ſcent, and are ſeldom produced ſo early in the ſeaſon. It may be propagated by laying down the tender branches, as was directed for the common white ſort; or by budding or inarching it upon the common yellow Jaſmine, the latter of which is preferable, as making the plants hardier than thoſe which are obtained from layers: they ſhould be planted againſt a warm wall, and in very ſevere winters will require to be ſheltered with mats, or ſome other covering, otherwiſe they are ſubject to be deſtroyed. The manner of dreſſing and pruning being the ſame as was directed for the white Jaſmine, I ſhall not repeat it.

The third ſort was formerly more cultivated in the gardens than at preſent, for as the flowers have no ſcent, ſo few perſons regard them. This hath weak angular branches which require ſupport, and will riſe to the height of eight or ten feet, if planted againſt a wall or pale; but the plants do often produce a great number of ſuckers from their roots, whereby they become troubleſome in the borders of the pleaſure-garden; and as they cannot be kept in any order as ſtandards, ſo there are few of the plants at preſent introduced into gardens. It is eaſily propagated by ſuckers or layers.

The fourth ſort grows naturally in India, and alſo in the iſland of Tobago, where the woods are full of it; the late Mr. Robert Millar ſent me over a great quantity of it from thence. This hath much ſtronger branches than the common white ſort; the leaves are winged, and are compoſed of three pair of ſhort obtuſe lobes, terminated by an odd one, ending in an acute point; theſe lobes are placed cloſer than thoſe of the common Jaſmine, and are of a lighter green; the flowers come out from the wings of the ſtalks, ſtanding on foot-ſtalks which are two inches long, each ſuſtaining three or four flowers, which are of a bluſh red on their outſide, but white within; the tube of the flower is longer, the ſegments are obtuſe, twiſted at the mouth of the tube, and are of a much thicker texture than thoſe of the common ſort, ſo that there is no doubt of its being a diſtinct ſpecies: the reaſon for Dr. Linnæus's ſuppoſing it to be ſo, was by miſtake; for as theſe plants are generally grafted upon ſtocks of the common Jaſmine, ſo there are always ſhoots coming out from the ſtocks of that ſort, which, if permitted to ſtand, will produce flowers; and theſe often ſtarve and kill the grafts, ſo that there will be only the common ſort left; and this has been the caſe with ſome plants which he examined, therefore ſuppoſed the difference of the other ſort was wholly owing to culture; whereas, if he had only obſerved the difference of their leaves, he would have certainly made two diſtinct ſpecies of them, which he has now done in the laſt edition of his ſpecies.

This plant is propagated by budding or inarching it upon the common white Jaſmine, on which it takes very well, and is rendered hardier than thoſe which are upon their own ſtocks. But the plants of this kind being brought over from Italy every ſpring in ſo great plenty, they are ſeldom raiſed here: I ſhall therefore proceed to the management of ſuch plants as are uſually brought into England from the place above-mentioned, which are generally tied up in ſmall bunches, containing four plants, and their roots wrapped about with moſs, to preſerve them from drying; which, if it happen that the ſhip has a long paſſage, will often occaſion them to puſh out ſtrong ſhoots from their roots, which muſt always be taken off before they are planted, otherwiſe they will exhauſt the whole nouriſhment of the plant, and deſtroy the graft.

In the making choice of theſe plants, you ſhould carefully obſerve if their grafts are alive, and in good health: for if they are brown and ſhrunk, they will not puſh out, ſo that there will be only the ſtock left, which is of the common ſort.

When you receive theſe plants, you muſt clear the roots of the moſs, and all decayed branches ſhould be taken off; then place their roots into a pot or tub of water, which ſhould be ſet in the green-houſe, or ſome other room, where it may be ſcreened from the cold; in this ſituation they may continue two days, after which you muſt prune off all the dry roots, and cut down the branches within four inches of the place where they were grafted, and plant them into pots filled with freſh light earth; then plunge the pots into a moderate hot-bed of tanners bark, obſerving to water and ſhade them, as the heat of the ſeaſon may require. In about a month or ſix weeks after they will begin to ſhoot, when you muſt carefully rub off all ſuch as are produced from the ſtock below the graft; and you muſt now let them have a great ſhare of air, by raiſing the glaſſes in the heat of the day; and as the ſhoots extend, they ſhould be topped, to ſtrengthen them, and by degrees ſhould be hardened to endure the open air, into which they ſhould be removed the beginning of June, but muſt have a warm ſituation the firſt ſummer; for if they are too much expoſed to the winds, they will make but indifferent progreſs, being rendered ſomewhat tender by the hot-bed. If the ſummer proves warm, and the trees have ſucceeded well, they will produce ſome flowers in the autumn following, though they will be few in number, and not near ſo ſtrong as they will be the ſucceeding years, when the trees are ſtronger and have better roots.

Theſe plants are commonly preſerved in green-houſes, with Oranges, Myrtles, &c. and during the winter ſeaſon, will require to be frequently watered; which ſhould be performed ſparingly each time, eſpecially in cold weather, for too much wet at that ſeaſon will be apt to rot the fibres of their roots; they ſhould alſo have a great ſhare of freſh air when the weather will permit, for which purpoſe they ſhould be placed in the cooleſt part of the green-houſe, among plants that are hardy, where the windows may be opened every day, except in froſty weather; nor ſhould they be crowded too cloſe among other plants, which often occaſions the tender part of their ſhoots to grow mouldy and decay. In April the ſhoots of theſe plants ſhould be ſhortened down to four eyes, and all the weak branches ſhould be cut off; and if you have the conveniency of a glaſs-ſtove, or a deep frame, to place the pots in at that ſeaſon, to draw them out again, it will be of great ſervice in forwarding their flowering; yet ſtill you ſhould be careful not to force them too much; and as ſoon as they have made ſhoots three or four inches long, the glaſſes ſhould be opened in the day time, that the plants may, by degrees, be inured to the open air, into which they ſhould be removed by the latter end of May, or the beginning of June; otherwiſe their flowers will not be ſo fair, nor continue ſo long. If the autumn prove favourable, theſe plants will continue to produce freſh flowers until November; and ſometimes when they are ſtrong, they will continue flowering later; but then they muſt have a great ſhare of air when the weather is mild and will admit of it, otherwiſe the flower-buds will grow mouldy and decay.

But notwithſtanding moſt people preſerve theſe plants in green-houſes, yet they will endure the cold of our ordinary winters in the open air, if planted againſt a warm wall, and covered with mats in froſty weather; they will alſo produce ten times as many flowers in one ſeaſon as thoſe kept in pots, and the flowers will likewiſe be much larger; but they ſhould not be planted abroad till they have acquired ſtrength, ſo that it will be neceſſary to keep them in pots three or four years, whereby they may be ſheltered from the froſt in winter; and when they are planted againſt the wall, which ſhould be in May, that they may take good root in the ground before the ſucceeding winter, you muſt turn them out of the pots, preſerving the earth to their roots; and having made holes in the border where they are to be planted, you ſhould place them therein, with their ſtems cloſe to the wall; then fill up the holes round their roots with good, freſh, rich earth, and give them ſome water to ſettle the ground about them, and nail up their ſhoots to the wall, ſhortening ſuch of them as are very long, that they may puſh out new ſhoots below to furniſh the wall, continuing to nail up all the ſhoots as they are produced. In the middle, or toward the latter end of July, they will begin to flower, and continue to produce new flowers until the froſt prevents them; which, when you obſerve, you ſhould carefully cut off all the tops of ſuch ſhoots as have buds formed upon them, as alſo thoſe which have the remains of faded flowers left; for if theſe are ſuffered to remain on, they will ſoon grow mouldy, eſpecially when the trees are covered, and thereby infect many of the tender branches, which will greatly injure the trees.

Toward the middle of November, if the weather proves cold and the nights froſty, you muſt begin to cover your trees with mats, which ſhould be nailed over them pretty cloſe; but this ſhould be done when the trees are perfectly dry, otherwiſe the wet being lodged upon the branches, will often cauſe a mouldineſs upon them, and the air being excluded therefrom, will rot them in a ſhort time: it will alſo be very neceſſary to take off the mats as ſoon as the weather will permit, to prevent this mouldineſs, and only keep them cloſe covered in froſty weather, and in the nights; at which time you ſhould alſo lay ſome mulch upon the ſurface of the ground about their roots, and faſten ſome bands of hay about their ſtems, to guard them from the froſt; and in very ſevere weather, you ſhould add a double or treble covering of mats over the trees; by which method, carefully performed, you may preſerve them through the hardeſt winters. In the ſpring, as the weather is warmer, you ſhould by degrees take off the covering; but you ſhould be careful not to expoſe them too ſoon to the open air, as alſo to guard them againſt the morning froſts and dry eaſterly winds, which often reign in March, to the no ſmall deſtruction of tender plants if they are expoſed thereto; nor ſhould you quite remove your covering until the middle of April, when the ſeaſon is ſettled; at which time you ſhould prune the trees, cutting out all decayed and weak branches, ſhortening the ſtrong ones to about two feet long, which will cauſe them to ſhoot ſtrong, and produce many flowers.

There is a variety of this with ſemi-double flowers, which is at preſent more rare in England, and only to be found in ſome curious gardens; though in Italy it is pretty common, from whence it is ſometimes brought over amongſt the ſingle; the flowers of this kind have only two rows of leaves, ſo that it is rather cultivated for its curioſity, than for any extraordinary beauty in the flowers. This may be propagated by budding it upon the common white Jaſmine, as hath been directed for the ſingle, and muſt be treated in the ſame manner.

The fifth ſort grows naturally in India; this riſes with an upright woody ſtalk eight or ten feet high, covered with a brown bark, ſending out ſeveral branches which want no ſupport; theſe are cloſely garniſhed with trifoliate leaves of a lucid green, which are placed alternate on the branches; the two ſide lobes of theſe leaves which grow oppoſite, are much leſs than the end one; they are oval and entire, continuing green all the year: the flowers are produced at the end of the ſhoots in bunches, which have long ſlender tubes, and are divided at the top into five obtuſe ſegments which ſpread open; theſe flowers are of a bright yellow, and have a moſt grateful odour. They come out in July, Auguſt, September, and October, and ſometimes continue to the end of November; they are frequently ſucceeded by oblong oval berries, which turn black when ripe, and have each two ſeeds.

This ſort of Jaſmine is propagated either by ſeeds, or laying down the tender branches; if you would propagate them by ſeeds, which they ſometimes produce in England, you ſhould make a moderate hot-bed in the ſpring, into which you ſhould plunge ſome ſmall pots, filled with freſh light earth; and in a day or two after, when you find the earth in the pots warm, you muſt put your ſeeds therein; about four in each pot will be ſufficient, covering them about an inch thick with the ſame light earth, and obſerve to refreſh the pots with water as often as you ſhall perceive the earth dry; but do not give them too much at each time, which would be apt to rot the ſeeds.

In about ſix or eight weeks after ſowing, the plants will appear above ground, at which time it will be neceſſary to remove the pots into another freſh hot-bed, of a moderate temperature, in order to bring the plants forward; you muſt alſo be careful to water them as often as is neceſſary, and in the great heat of the day the glaſſes ſhould be tilted pretty high, and ſhaded with mats, to prevent the plants from being ſcorched with heat. About the middle of May you ſhould begin to harden them to the open air, by taking off the glaſſes when the weather is warm; but this muſt be done cautiouſly, for you ſhould not expoſe them to the open ſun in a very hot day at firſt, which would greatly injure them; but rather take off the glaſſes in warm cloudy weather at firſt, or in gentle ſhowers of rain, and ſo by degrees inure them to bear the ſun; and in June you ſhould take the pots out of the hot-bed, and carry them to ſome well ſheltered ſituation, where they may remain until the beginning of October; at which time they muſt be carried into the green-houſe, obſerving to place them where they may enjoy as much free air as poſſible when the windows are opened, as alſo to be clear from the branches of other plants.

During the winter ſeaſon they will require to be often watered, but you muſt be careful not to give them too much at each time; and in March you muſt remove theſe plants each into a ſeparate pot, being careful not to take the earth from their roots; and if at this time you plunge them into a freſh moderate hot-bed, it will greatly facilitate their rooting again, and be of great ſervice to the plants; but when they are rooted, you muſt give them a great deal of air; for if you draw them too much, they will become weak in their ſtems, and incapable to ſupport their heads, which is a great defect in theſe trees.

You muſt alſo harden them to the open air, into which they ſhould be removed about the middle of May, obſerving, as was before directed, to place them in a ſituation that is defended from ſtrong winds, which are injurious to theſe plants, eſpecially while they are young. In winter houſe them as before, and continue the ſame care, with which they will thrive very faſt, and produce annually great quantities of flowers.

Theſe plants are pretty hardy, and will require no other care in winter, than only to defend them from hard froſts; nor do I know whether they would not live in the open air, if planted againſt a warm wall, which is what ſhould be tried by planting ſome againſt a wall for that purpoſe; and I think we have little reaſon to doubt of the ſucceſs, ſince they are much hardier than the Spaniſh; but there is this difference between them, viz. theſe plants have large, thick, Evergreen leaves, ſo that if they were covered with mats, as was directed for the Spaniſh Jaſmine, the leaves would rot and decay the ſhoots; but as theſe will only require to be covered in extreme froſt, ſo if their roots are well mulched, and a mat or two looſely hung over them in ordinary froſts, it will be ſufficient; and theſe mats being either rolled up, or taken quite off in the day, there will be no great danger of their being hurt, which only can proceed from being too long cloſe covered.

In the ſpring theſe ſhould be pruned, when you ſhould cut off all decayed branches; but you muſt not ſhorten any of the other branches, as was directed for the Spaniſh ſort, for the flowers of this kind are produced only at the extremity of the branches, which, if ſhortened, they would be cut off; and theſe growing of a more ligneous ſubſtance than the other, will not produce ſhoots ſtrong enough to flower the ſame year.

If you would propagate this plant from layers, the ſhoots ſhould be laid down in March; and if you give them a little cut at the joint, as is practiſed in laying of Carnations, it will promote their rooting: you ſhould always obſerve to refreſh them often with water, when the weather is dry; which, if carefully attended to, the plants will be rooted by the ſucceeding ſpring, fit to be tranſplanted, when they muſt be planted in pots filled with light earth, and managed as was before directed for the ſeedling plants.

This ſort is frequently propagated, by inarching the young ſhoots into ſtocks of the common yellow Jaſmine, but the plants ſo raiſed do not grow ſo ſtrong as thoſe which are upon their own ſtock; beſides, the common yellow Jaſmine is very apt to ſend out a great number of ſuckers from the root, which renders the plants unſightly; and if theſe ſuckers are not conſtantly taken off as they are produced, they will rob the plants of their nouriſhment.

The ſixth ſort grows naturally in the Azores; this hath long ſlender branches which require ſupport, and may be trained twenty feet high; they are garniſhed with trifoliate leaves, whoſe lobes are large and heart-ſhaped, of a lucid green, and are placed oppoſite on the branches; they continue all the year. The flowers are produced at the end of the branches, in looſe bunches; they have long narrow tubes, which at the top are cut into five ſegments ſpreading open; they are of a clear white, and have a very agreeable ſcent. This flowers at the ſame time with the former; the gardeners call it frequently the Ivy-leaved Jaſmine.

The Azorian Jaſmine is alſo pretty hardy, and requires no more ſhelter than only from hard froſts; and I am apt to think, if this ſort was planted againſt a warm wall, and managed as hath been directed for the yellow Indian Jaſmine, it would ſucceed very well; for I remember to have ſeen ſome plants of this kind growing againſt a wall in the gardens at Hampton Court, where they had endured the winter, and were in a more flouriſhing ſtate than ever I ſaw any of the kind in pots, and produced a greater quantity of flowers. Theſe plants are propagated in the ſame manner as the yellow Indian, and require the ſame management.

Theſe plants are as deſerving of a place in all green-houſes, as any which are there preſerved; for their leaves being of a ſhining green, make a good appearance all the year; and their flowers having a fine ſcent, and continuing ſo long in ſucceſſion, renders them very valuable.

The ſeventh ſort was brought from the Cape of Good Hope, by Captain Hutchinſon of the Godolphin, who diſcovered it growing naturally, a few miles up the land from the ſea, being drawn to it by the great fragrancy of its flowers, which he ſmelt at ſome diſtance from the plant, which was then in full flower; and after having viewed the plant, and remarked the place of its growth, he returned thither the following day with proper help, and a tub to put it in, and cauſed it to be carefully taken up, and planted in the tub with ſome of the earth on the ſpot, and conveyed on board his ſhip, where it continued flowering great part of the voyage to England, where it arrived in good health, and has for ſome years continued flowering, in the curious garden of Richard Warner, Eſq; at Woodford in Eſſex, who was ſo obliging as to favour me with branches of this curious plant in flower, to embelliſh one of the numbers of my figures of plants, where it is repreſented in the 180th plate.

This plant ſeems not to have been known to any of the botaniſts, for I have not met with any figure or deſcription of it in any of the books; there is one ſort which is figured in the Malabar garden, and alſo in Burman's plants of Ceylon, which approaches near this; it is titled Nandi ervatum major. Hort. Mal. But it differs from this, in having longer and narrower leaves; the tube of the flower is larger, and the ſegments do not ſpread ſo much as this; the flowers alſo of the Cape Jaſmine fade to a buff colour before they decay, therefore there is no doubt of its being a different ſpecies from that of Dr. Burman; but it is ſurprizing that this plant ſhould be unknown to the people at the Cape of Good Hope, for there was not one plant of it in their curious garden, nor could the captain ſee any other plant of it but that which he brought away.

The ſtem of this plant is large and woody, ſending out many branches, which are firſt green, but afterward the bark becomes gray and ſmooth; the branches come out by pairs oppoſite, and have ſhort joints; the leaves are alſo ſet oppoſite, cloſe to the branches; they are five inches long, and two inches and a half broad in the middle, leſſening to both ends, terminating in a point; they are of a lucid green, having ſeveral tranſverſe veins from the midrib to the borders; they are entire, and of a thick conſiſtence. The flowers are produced at the end of the branches, ſitting cloſe to the leaves; they have a tubulous empalement, with five corners or angles, cut deep at the brim, into five long narrow ſegments, ending in acute points: the flower hath but one petal, for although it is cut into many deep ſegments at the top, yet theſe are all joined in one tube below; ſome of theſe flowers are much more double than others, having three or four orders of petals; theſe which have ſo many, have only a bifid ſtigma, but thoſe which are leſs double have trifid ſtigmas. All thoſe flowers which I have examined have but one or two ſtamina, which may be occaſioned by the fulneſs of the flowers; as is often obſerved in many kinds of plants, whoſe flowers have a greater number of petals than uſual, many of which want both parts of generation, and ſome of them have no male parts. This flower, when fully blown, is as large as a middling Roſe, and ſome of them are as double as the Damaſk Roſe; they have a very agreeable odour; on the firſt approach it is ſomething like that of the Orange flower, but when more cloſely ſmelt to, has the odour of the common double white Narciſſus. The ſeaſon of this plant flowering in England, is in July and Auguſt, but in its native country it is ſuppoſed to flower great part of the year; for Captain Hutchinſon, who brought the plant over, ſaid there was a ſucceſſion of flowers on it, till the ſhip arrived in a cold climate, which put a ſtop to its growth.

Dr. Linnæus has been induced from what has been printed in the Tranſactions of the Royal Society, to alter the title of this plant to Gardenia; but as the deſcription of the plant with its characters as there printed, was taken from a double flower by ſome haſty people, who ſhould have remembred what Linnæus has written to caution perſons againſt regarding the double flowers of all kinds, in ranging them in their claſſes and genera, which if they had adhered to, they would not have made this miſtake; for I have ſince raiſed ſeveral of the plants from ſeeds, ſome of which have produced flowers which were ſingle, having all the marks of the double, the flowers altering to a buff colour before they faded; and all theſe flowers had each but three ſtamina and a trifid ſtigma; whereas in the characters ſet down by Linnæus, there is no ſtamina, but five linear antheræ, by which it is plain from the increaſe of the number of petals (or rather their ſegments) has occaſioned an alteration in the parts of generation; which is alſo very conſpicuous in the double flowers of Dianthus, where ſome flowers have but two or three ſtamina, when the ſame ſpecies with ſingle flowers have uſually ten. Linnæus alſo ſuppoſes the capſule of the ſeed to have two cells full of ſmall ſeeds; but the perſons who led him into this miſtake, have ſince ſuppoſed the figure given by Dr. Plukenet in his 448th plate, under the title of Um-ky, to be the fruit of this plant; whereas this has three cells filled with angular ſweet-ſcented ſeeds, as the ſpecimens I have of that demonſtrate, by which it is certain they are the fruit of a different plant; for the ſeeds which I ſowed of this Jaſmine, were a berry compoſed of two ſeeds like the other Jaſmines; therefore I have continued it under the ſame genus, with an addition to the title of its having three ſtamina.

This plant is eaſily propagated by cuttings during the ſummer ſeaſon; the cuttings ſhould be planted in pots, and plunged into a moderate hot-bed, covering them cloſe with either bell or hand-glaſſes to exclude the external air, being careful to ſcreen them from ſun in the day time; when they have taken root they ſhould be carefully parted, and put each into a ſeparate ſmall pot, plunging them again into the hot-bed, and ſhading them until they have taken new root, after which they ſhould be gradually inured to the open air.

Though the cuttings of this plant take root freely, and make ſtrong ſhoots a year or two after, yet in three or four years they are very apt to ſtint in their growth, their leaves turning pale and ſickly, and frequently die ſoon after; this has happened every where within my knowledge, although the plants have been kept in various degrees of heat in winter; and in ſummer when they have been differently managed, they have frequently failed. I have alſo been informed by a gentleman who lived ſome years in India, where he had the plants in his garden, they frequently went off in the ſame manner. This has greatly leſſened the value of the plants in England.

JATROPHA. Lin. Gen. Plant. 961. Manihot. Tourn. Inſt. R. H. 958. tab. 438. Caſſada, or Caſſava; in French *Caſſave.*

The CHARACTERS are,

It hath male and female flowers in the ſame plant; the male flowers have a ſcarce viſible empalement; they are ſalver-ſhaped, of one petal, with a ſhort tube, whoſe brim is cut into five roundiſh ſegments which ſpread open; they have ten awl-ſhaped ſtamina, five being alternately ſhorter than the other, and are joined cloſe together, ſtanding erect in the center of the flower, terminated by roundiſh looſe ſummits. The female flowers which are ſituated in the ſame umbel have no empalement, but have five petals ſpread open like a Roſe. In the center is a roundiſh germen with three deep furrows, ſupporting three ſtyles, crowned by ſingle ſtigmas. The germen afterward becomes a roundiſh capſule with three cells, each containing one ſeed.

This genus of plants is ranged in the ninth ſection of Linnæus's twenty-firſt claſs, intitled Monœcia Monodelphia,

nodelphia, which includes thoſe plants which have male and female flowers on the ſame plant, and the ſtamina are collected in one body.

The Species are,

1. JATROPHA (*Manihot*) foliis palmatis, lobis lanceolatis integerrimis lævibus. Lin. Sp. Plant. 1007. *Jatropha with hand-ſhaped leaves, whoſe lobes are ſpear-ſhaped, entire, and ſmooth.* Manihot Theveti, juca & caſſavi. J. B. 2. 794. *The Manihot of Thevet, and the Juca or Caſſava of John Bauhin.*
2. JATROPHA (*Quinquelobatus*) foliis quinquelobatis, lobis acuminatis, acutè dentatis lævibus, caule fruticoſo. *Jatropha with leaves compoſed of five ſmooth lobes ending in points, which are ſharply indented on their edges, and a ſhrubby ſtalk.* Juſſievia fruteſcens, non ſpinoſa, foliis glabris & minus laciniatis. Houſt. MSS. *Shrubby Juſſievia without ſpines, and ſmooth leaves leſs divided.*
3. JATROPHA (*Urens*) aculeata, foliis quinquelobatis acutè inciſis, caule herbaceo. *Prickly Jatropha, with leaves having five lobes which are ſharply cut on their edges, and an herbaceous ſtalk.* Juſſievia herbacea, ſpinoſiſſima, urens, foliis digitatis & laciniatis. Houſt. MSS. *The moſt prickly ſtinging and herbaceous Juſſievia, with fingered leaves which are jagged.*
4. JATROPHA (*Herbacea*) aculeata, foliis trilobis, caule herbaceo. Lin. Sp. Plant. 1007. *Prickly Jatropha, with leaves having three lobes and an herbaceous ſtalk.* Juſſievia herbacea ſpinoſiſſima, urens, foliis trilobatis minimè inciſis. Houſt. MSS. *Prickly ſtinging herbaceous Juſſievia, with leaves having three lobes, which are very ſlightly indented.*
5. JATROPHA (*Vitifolius*) foliis palmatis dentatis aculeatis. Hort. Cliff. 445. *Jatropha with hand-ſhaped, indented, prickly leaves.* Manihot ſpinoſiſſima, folio vitigineo. Plum. Cat. 20. *The moſt prickly Caſſava with a Vine leaf.*
6. JATROPHA (*Aconitifolius*) foliis lobatis dentatis acuminatis, urentibus, caule arboreo. *Jatropha with lobated leaves which are indented, acute-pointed, and ſtinging, and a tree-like ſtalk.* Juſſievia arborea, minùs ſpinoſa, floribus albis umbellatis, foliis aconiti urentibus. Houſt. MSS. *Tree Juſſievia which is leſs prickly, with white flowers growing in umbels, and ſtinging leaves like thoſe of Wolfsbane.*
7. JATROPHA (*Multifida*) foliis multipartitis lævibus, ſtipulis ſetaceis multifidis. Hort. Cliff. 445. *Jatropha with ſmooth leaves divided into many parts, and briſtly ſtipulæ with many points.* Ricinoides arbor Americana, folio multifido. 656. *Tree American Baſtard Ricinus with a many pointed leaf, commonly called French Phyſic Nut in America.*
8. JATROPHA (*Curcas*) foliis cordatis angulatis. Hort. Cliff. 445. *Jatropha with angular heart-ſhaped leaves.* Ricinoides Americana goſſypii folio. Tourn. Inſt. 656. *American Baſtard Ricinus with a Cotton leaf, commonly called Phyſic Nut in America.*
9. JATROPHA (*Staphyſagrifolia*) foliis quinquepartitis, lobis ovatis integris, ſetis glanduloſis ramoſis. Flor. Leyd. Prod. 202. *Jatropha with leaves divided into five parts, the lobes whereof are oval and entire, and branching briſtles ariſing from the glands.* Ricinoides Americana ſtaphyſagriæ folio. Tourn. Inſt. 656. *American Baſtard Ricinus, with a Staveſacre leaf, commonly called Belly-ach Weed in America.*

The firſt ſort here mentioned, is the common Caſſada or Caſſava, which is cultivated for food in the warm parts of America, where, after the juice is expreſſed out of the root (which has a poiſonous quality) it is ground into a kind of flour, and made up in cakes or puddings, and is eſteemed a wholeſome food.

This riſes with a ſhrubby ſtalk ſix or ſeven feet high, garniſhed with ſmooth leaves, ſtanding upon long foot-ſtalks alternately; they are compoſed of ſeven lobes, which are joined at their baſe in one center, where they are narrow, but increaſe in their breadth till within an inch and a half of the top, where they diminiſh to an acute point; the three middle lobes are about ſix inches long, and two broad in their broadeſt part; the two next are about an inch ſhorter, and the two outſide lobes are not more than three inches long; the middle lobes are ſinuated on each ſide near the top, but the two outer are entire. The flowers are produced in umbels at the top of the ſtalks, thoſe are ſome male and others female in the ſame umbel; they are compoſed of five roundiſh petals which ſpread open; the male flowers have their ten ſtamina joined together in a column, and the female flowers have a roundiſh germen with three furrows in the center, ſupporting three ſtyles; two are ſeparated at a diſtance, and the third ariſes between them, but is not ſo long; they are crowned by ſingle ſtigmas. The germen afterward turns to a roundiſh capſule with three lobes, each having a diſtinct cell, containing one ſeed.

The ſecond ſort was diſcovered by the late Dr. Houſtoun at the Havanna, from whence he ſent the ſeeds. This riſes with an upright ſtalk ten or twelve feet high, which is firſt green and herbaceous, but afterward becomes ligneous, ſending out a few branches at the top, which are garniſhed with ſmooth leaves, compoſed of five oval lobes, which end in acute points; the edges are alſo indented in ſeveral irregular points, which are acute. The flowers are produced in an umbel at the extremity of the ſtalks, they are of an herbaceous white colour, and are male and female in the ſame umbel, as the other ſort; the capſule is ſmooth and has three cells, each including a ſingle ſeed.

The third ſort was diſcovered by the late Dr. Houſtoun, growing naturally in the ſandy grounds about the town of La Vera Cruz, from whence he ſent the ſeeds, which ſucceeded in the Chelſea garden. This hath a very thick fleſhy root, in ſhape like the white Spaniſh Radiſh; the ſtalk riſes from one to two feet high, it is taper, herbaceous, and branching, and cloſely armed on every ſide with long white ſpines, which are not very ſtiff, but are pungent and ſtinging; the leaves are divided into five lobes, the middle being the longeſt; the others are ſhortened, the two next being about an inch ſhorter, but the two outer are not more than half the length of the middle; theſe are deeply jagged on both ſides, and are waved on their edges; all the veins of the leaves are cloſely armed with ſtinging ſpines, ſo that it is dangerous handling them; for all the intermediate parts of the leaves have ſmall ſtinging ſpines like thoſe of the Nettle, but they do not appear ſo viſible. At the end of the branches the flowers are produced in umbels; they are white, and have empalements cloſely armed with the ſame ſpines as the ſtalks and leaves: there are male and female flowers in the ſame umbel; the female flowers are ſucceeded by tricapſular veſſels, containing three ſeeds.

The fourth ſort riſes with an herbaceous ſtalk about a foot high, dividing into two or three branches, which are garniſhed with leaves ſtanding alternate upon long foot-ſtalks; they are compoſed of three oblong lobes which are ſlightly ſinuated on their edges, ending in acute points; the whole plant is cloſely armed with long, briſtly, ſtinging ſpines. The flowers grow in an umbel at the end of the branches; they are ſmall, of a dirty white colour, and are male and female in the ſame umbel: the female flowers are ſucceeded by oval capſules with three lobes, which are covered with the ſame ſpines as the plant; theſe have three cells, each containing a ſingle ſeed. This plant is annual.

The fifth ſort was found growing naturally at Carthagena in New Spain, by the late Mr. Robert Millar, who ſent the ſeeds to England, which ſucceeded in ſeveral curious gardens. This hath a thick, ſwelling, fleſhy root, from which ariſes an herbaceous ſtalk as big as a man's thumb, which is four or five feet high, and divides into ſeveral branches; theſe are very cloſely armed with long brown ſpines; the foot-ſtalks of the leaves are ſix or ſeven inches long, which are alſo armed with ſpines, but not ſo cloſely, nor are the ſpines ſo long as thoſe on the ſtalk and branches; the leaves are deeply cut into five lobes, which are jagged deeply on their ſides, and the nerves are armed with ſtinging ſpines; the flowers are produced in umbels at the top of the branches, ſtanding upon long naked foot-ſtalks; they are of a pure white colour, and are male and female in the ſame umbel: the male flowers appear firſt, which are compoſed of five petals, forming a ſhort tube at bottom, and the ſtamina ariſe the length of the tube, joined in a column: the petals ſpread open flat above, and the ſtamina fills the mouth of the tube, ſhutting it up: the female flowers are ſmaller, but of the ſame ſhape, having no ſtamina, but an oval three-cornered germen, which afterwards becomes a capſule with three lobes, each having a diſtinct cell, with one ſeed incloſed.

The ſixth ſort was diſcovered by the late Dr. Houſtoun at La Vera Cruz, where it is frequently permitted to grow about the town by way of ornament; this riſes with a ſtrong, brittle, ligneous ſtalk, ten or twelve feet high, covered with a gray bark, and divides into many branches, which are garniſhed with leaves, that are divided into parts like thoſe of the common Woolfsbane, but are armed with ſmall ſtinging ſpines like thoſe of the Nettle; at the end of the branches come out the flower-ſtalks, which are five or ſix inches long, ſuſtaining an umbel of white flowers. The male flowers are of one petal, having a pretty long tube, which is divided at the top into five ſegments. The female flowers expand in form of a Roſe, having the germen in the center, which afterward becomes a globular prickly fruit with three lobes, opening in three cells, each containing a ſingle ſeed.

The ſeventh ſort is now very common in moſt of the iſlands in the Weſt-Indies, but was introduced from the continent, firſt into the French iſlands, and from thence it was brought into the Britiſh iſlands, where it is titled French Phyſic Nut, to diſtinguiſh it from the following ſort, which is called Phyſic Nut, from its purging quality.

This riſes with a ſoft thick ſtem eight or ten feet high, dividing into ſeveral branches, covered with a grayiſh bark. The leaves come out on every ſide the branches on ſtrong foot-ſtalks, which are ſeven or eight inches long; they are divided into nine or ten lobes in form of a hand, which are joined at their baſe; theſe are ſeven inches long, and about two inches broad, with many jagged points on their borders ſtanding oppoſite. The upper ſide of the leaves are of a lucid green, but their under ſide gray, and a little cottony. The flowers come out upon long foot-ſtalks from the end of the branches, formed into an umbel, in which there are male and female flowers, as in the other ſpecies; theſe umbels are large, and the flowers being of a bright ſcarlet, they make a fine appearance; and the leaves being very remarkable for their beauty, has occaſioned the plant being cultivated for ornament in moſt of the iſlands of the Weſt-Indies.

The eighth ſort grows naturally in all the iſlands of the Weſt-Indies; this riſes with a ſtrong ſtalk twelve or fourteen feet high, which divides into ſeveral branches; theſe are garniſhed with angular heart-ſhaped leaves, which end in acute points. The flowers come out in umbels at the end of the branches; they are male and female, of an herbaceous colour, ſo make but little appearance; the female flowers are ſucceeded by oblong oval capſules with three cells, each containing one oblong black ſeed.

The ſeeds of the two laſt ſorts have been uſed as a purgative by the inhabitants of the Weſt-Indies, but they operate ſo violently, that now they are ſeldom uſed; three or four of theſe nuts have worked upward and downward near forty times, on a perſon who was ignorant of their effects; but it is affirmed that this purgative quality is contained in a thin film, ſituated in the center of the nut, which, if taken out, the nuts are harmleſs, and may be eaten with ſafety. The leaves of the laſt ſort are uſed in baths and fomentations.

The ninth ſort grows naturally in all the iſlands of the Weſt-Indies, where it is ſometimes called wild Caſſada, or Caſſava, and at others Belly-ach Weed, the leaves of this plant being accounted a good remedy for the dry belly-ach. This plant riſes with a ſoft herbaceous ſtalk to the height of three or four feet, covered with a purple bark, and at the joints have branching briſtly hairs riſing in ſmall bunches, not only upon the principal ſtalk, but alſo on the branches, and the foot-ſtalks of the leaves. The ſtalk divides upward into two or three branches; theſe are garniſhed with leaves ſtanding on very long foot-ſtalks, divided into five lobes which are oval, entire, and end in acute points. The flowers are produced at the end of the branches, upon ſlender naked foot-ſtalks, in ſmall umbels; they are ſmall, of a dark purple colour, having male and female flowers in the ſame umbel; the female flowers are ſucceeded by oblong tricapſular veſſels, ſmooth, and covered with a dark ſkin, when ripe; in each of the cells is lodged one oblong brown ſeed.

All theſe plants are natives of the warm parts of America, ſo are too tender to thrive in the open air in England. The firſt ſort is cultivated in the Weſt-Indies for food, where it is propagated by cutting the ſtalks into lengths of ſeven or eight inches, which, when planted, put out roots; the method of doing this having been mentioned in various books, I ſhall not repeat it here.

The other ſorts are eaſily propagated by ſeeds, which ſhould be ſown on a good hot-bed in the ſpring, and when the plants are fit to remove, they ſhould be each tranſplanted into a ſmall pot filled with light earth, and then plunged into a freſh hot-bed of tanners bark, carefully ſhading them till they have taken freſh root; after which they muſt be treated in the ſame manner as other tender plants from hot countries, admitting freſh air to them daily, in proportion to the warmth of the ſeaſon; but as many of the ſorts have ſucculent ſtalks, ſome of which have a milky juice, they ſhould have but little water given them, for they are ſoon deſtroyed by wet.

The fourth ſort is an annual plant, ſo if the ſeeds are ſown early in the ſping, and the plants are brought forward, they will perfect their ſeeds the ſame year; but the other ſorts are perennial, ſo do not flower till the ſecond or third year; therefore the plants ſhould be plunged into the tan-bed in the ſtove, where they ſhould conſtantly remain, giving them a large ſhare of air in warm weather; but in winter they muſt be tenderly treated, and in that ſeaſon muſt have very little water. With this management the plants will continue ſeveral years, and produce their flowers, and frequently perfect their ſeeds in England.

IBERIS. Dillen. Nov. Gen. 6. Lin. Gen. Plant. 721. Thlaſpidium. Tourn. Inſt. R. H. 214. tab. 101. Sciatica Creſs.

The Characters are,

The flower hath an empalement of four oval leaves, which ſpread open, are hollowed and fall away. It hath four unequal petals, which are oval, obtuſe, and ſpread open, having oblong erect tails; the two outer petals are longer than the other. It hath ſix awl-ſhaped erect ſtamina, the two on the ſides being ſhorter than the reſt, terminated by roundiſh ſummits. In the center of the tube is ſituated a round compreſſed germen, ſupporting a ſhort ſingle ſtyle, crowned by an obtuſe ſtigma. The germen afterward becomes a roundiſh compreſſed veſſel, having two cells, each containing one oval ſeed.

This genus of plants is ranged in the firſt ſection of Linnæus's fifteenth claſs, intitled Tetradynamia Siliculoſa, which includes thoſe plants whoſe flowers have four long and two ſhort ſtamina, and the ſeeds grow in ſhort pods.

The Species are,

1. Iberis (*Semperflorens*) fruteſcens, foliis cuneiformibus obtuſis integerrimis. Lin. Hort. Cliff. 330. *Shrubby Sciatica Creſs with entire, wedge-ſhaped, blunt leaves, commonly called the Tree Candy Tuft.* Thlaſpidium fruticoſum, leucoii folio, ſemperflorens. Tourn. Inſt. 214. *Shrubby Thlaſpidium with a Gilliflower leaf, always flowering.*

2. Iberis (*Sempervirens*) fruteſcens foliis linearibus acutis integerrimis. Lin. Hort. Cliff. 330. *Shrubby Sciatica Creſs with narrow-pointed whole leaves, commonly called Perennial Candy Tuft.* Thlaſpi montanum, ſempervirens. C. B. P. 106. *Evergreen Mountain Candy Tuft.*

3. Iberis (*Umbellata*) herbacea foliis lanceolatis acuminatis, inferioribus ſerratis, ſuperioribus integerrimis. Lin. Hort. Cliff. 330. *Herbaceous Sciatica Creſs with ſpear-ſhaped pointed leaves, the under ones being ſawed, but the upper entire, commonly called Candy Tuft.* Thlaſpi Creticum quibuſdam, flore rubente & albo. J. B. 2. 924. *True Cretan Treacle Muſtard with a red and white flower.*

4. Iberis (*Odorata*) foliis linearibus ſupernè dilatatis ſerratis. Flor. Leyd. 330. *Sciatica Creſs with narrow leaves dilated at their top, and ſawed.* Thlaſpi umbellatum Creticum, flore albo odoro, minus. C. B. P. 106. *Small umbellated Treacle Muſtard of Crete with a white ſweet flower.*

5. Iberis (*Nudicaulis*) herbacea foliis ſinuatis, caule nudo ſimplici. Lin. Hort. Cliff. 328. *Sciatica Creſs with ſinuated leaves, and a ſingle naked ſtalk.* Naſturtium petræum. Tab. Ic. 451. *Rock Creſs.*

6. Iberis (*Amara*) herbacea foliis lanceolatis acutis ſubdentatis, floribus racemoſis. Lin. Hort. Upſal. 184. *Sciatica Creſs with acute, ſpear-ſhaped, indented leaves, and flowers growing in bunches.* Thlaſpi avenſe umbellatum amarum. J. B. 2. 925. *Bitter, umbellated, Field Treacle Muſtard.*

7. Iberis (*Rotundifolia*) foliis ſubrotundis crenatis. Royen. Lin. Sp. Plant. 49. *Iberis with roundiſh crenated leaves.* Thlaſpi Alpinum, folio rotundiore carnoſo, flore purpuraſcente. Tourn. Inſt. 112. *Alpine Treacle Muſtard with a rounder fleſhy leaf, and a purpliſh flower.*

8. Iberis (*Linifolia*) fruteſcens, foliis linearibus acutis, corymbis hemiſphæricis. *Shrubby Sciatica Creſs with narrow acute leaves, and hemiſpherical bunches of flowers.* Thlaſpi Luſitanicum umbellatum, gramineo folio, purpuraſcente flore. Tourn. Inſt. R. H. 213. *Portugal, umbellated, Treacle Muſtard, with a Graſs leaf and a purpliſh flower.*

The firſt ſort here mentioned is a low ſhrubby plant, which ſeldom riſes above a foot and a half high, having many ſlender branches, which ſpread on every ſide, and fall toward the ground if they are not ſupported. Theſe branches are well furniſhed with leaves toward their extremity, which continue green all the year; and in ſummer the flowers are produced at the end of the ſhoots, which are white, and grow in an umbel. Theſe flowers continue long in beauty, and are ſucceeded by others, ſo that the plants are rarely deſtitute of flowers for near eight months, from the end of Auguſt to the beginning of June, which renders the plant valuable.

This plant is ſomewhat tender, therefore is generally preſerved in green-houſes in winter, where, being placed among other low plants toward the front of the houſe, it makes an agreeable variety, as it continues flowering all the winter. But although it is commonly ſo treated, yet in moderate winters this plant will live in the open air, if it be planted in a warm ſituation and on a dry ſoil; and if, in very hard froſt, they are covered either with mats, Reeds, Straw, or Peas-haulm, they may be preſerved very well; and theſe plants which grow in the full ground, will thrive better, and produce a greater number of flowers, than thoſe which are kept in pots; but the ſoil in which theſe are planted, ſhould not be over rich, nor too wet, for in either of theſe they will grow too vigorous in ſummer, ſo will be in greater danger of ſuffering by the froſt in winter; but when they grow on a gravelly ſoil, or among lime rubbiſh, their ſhoots will be ſhort, ſtrong, and not ſo replete with moiſture, ſo will better reſiſt the cold.

This plant very rarely produces ſeeds in England, therefore is only propagated by cuttings, which, if planted during any of the ſummer months, and ſhaded from the ſun, and duly watered, will be rooted in two months, and may afterward be either planted in pots, or into the borders where they are deſigned to ſtand.

There is a variety of this with variegated leaves, which is preſerved in ſome of the gardens where perſons delight in theſe ſtriped-leaved plants. This is not ſo hardy as the plain ſort, therefore muſt be treated more tenderly in winter; this is alſo increaſed by cuttings in the ſame manner as the other.

The ſecond ſort is a plant of humbler growth than the firſt; this ſeldom riſes more than ſix or eight inches high, nor do the branches grow woody, but are rather herbaceous; the leaves of this plant continue green through the year, and the flowers are of as long duration as thoſe of the firſt ſort, which renders it valuable. This rarely produces ſeeds in England, but is propagated by ſlips, which in ſummer eaſily take root, and the plants may be treated in the ſame manner as hath been directed for the firſt ſort, and will thrive in the open air.

The third ſort is a low annual plant, the ſeeds of which were formerly ſown to make edgings for borders in the pleaſure-garden, for which purpoſe all the low annual flowers are very improper, becauſe they do not anſwer the intent, which is to prevent the earth of the borders falling into the walks, which theſe plants never can do; and though they make a pretty appearance during their continuance in flower, which is ſeldom more than a fortnight or three weeks, yet after their flowers are paſt they become very unſightly; therefore all theſe ſorts of flowers ſhould be ſown in ſmall patches in the borders of the flower-garden, where, if they are properly mixed with other flowers, they will have a very good effect; and by ſowing of them at three or four different ſeaſons, there may be a ſucceſſion of them continued in flower till autumn.

There are two different varieties of this third ſort, one with red, and the other hath white flowers; but the white is not common in the gardens, but the ſeeds of the ſixth ſort are generally ſold for it, and is ſeldom diſtinguiſhed but by thoſe who are ſkilled in botany: this plant ſeldom riſes more than five or ſix inches high, and if they have room will branch out on every ſide, but when they are left too cloſe, they draw each other up, and are weak: as theſe do not bear tranſplanting well, ſo the ſeeds ſhould be ſown thin in patches, and when the plants are grown pretty ſtrong, they ſhould be thinned, leaving but ſix or eight in each patch to flower; and by thus treating them, they will put out ſide branches, and flower much ſtronger, and continue longer in beauty than when they are left cloſer together; theſe plants will require no other culture but to keep them clean from weeds.

The fourth ſort ſeldom grows ſo large as the third, and the flowers are much ſmaller, but have an agreeable odour. It grows naturally in Helvetia, and is preſerved in botanic gardens for variety. It is annual, and requires the ſame treatment as the third.

The fifth ſort grows on ſandy and rocky places in ſeveral parts of England, ſo is rarely admitted into gardens. The leaves of this are ſmall, and cut to the midrib into many jags; theſe are ſpread on the ground, and between them ariſe a naked foot-ſtalk two or three inches long, ſuſtaining ſmall umbels of white flowers. This is an annual plant, whoſe ſeeds ſhould be ſown in autumn where the plants are deſigned to remain, and require no other care but to keep them clean from weeds.

The ſixth ſort is very like the third, but differs in the ſhape of the leaves. The flowers of this are white, ſo may be ſown to make a variety with the red. It requires the ſame treatment.

The ſeventh ſort grows naturally on the Alps, from whence it was ſent me; this is a perennial plant, which roots pretty deep in the ground. The lower leaves which riſe from the root, are round, fleſhy, and crenated on their edges. The ſtalk riſes four or five inches high, and is garniſhed with ſmall oblong leaves which half embrace the ſtalks with their baſe. The flowers terminate the ſtalk in a round compact

pact umbel; they are of a purple colour, and appear in June, but are ſeldom ſucceeded by ſeeds in England.

It is propagated by ſeeds, which ſhould be ſown on a ſhady border in autumn, and when the plants are ſtrong enough to remove, they ſhould be tranſplanted on a ſhady border where they are deſigned to remain, and will require no other care but to keep them clean from weeds.

The eighth ſort grows naturally in Spain and Portugal; this hath a great reſemblance of the ſecond, but the ſtalks do not ſpread ſo much; they grow erect, about ſeven or eight inches high, are ligneous and perennial. The leaves are very narrow, and ſeldom more than an inch long, ſtanding thinly upon the ſtalks, having no foot-ſtalks. The flowers grow in hemiſpherical umbels on the top of the ſtalks, and are of a purple colour. It flowers in May and June, but ſeldom produces good ſeeds here.

This ſort may be propagated by cuttings, which ſhould be treated in the ſame way as is before directed for the firſt ſort; and ſome of the plants may be planted on a warm border in a dry ſoil, where they will endure the cold of our ordinary winters very well; but it will be proper to have two or three plants in pots, which may be ſheltered under a frame in winter, to preſerve the kind, if, by ſevere froſt, thoſe in the open air ſhould be deſtroyed.

IBISCUS. See HIBISCUS.

ICACO. See CHYRSOBALANUS.

ICE is a hard tranſparent body, formed from ſome liquor congealed, or fixed.

Ice is ſaid to be the natural ſtate of water, which remains firm, and not liquid, when no external cauſe acts upon it.

The true cauſe of the congelation of water into Ice, ſeems to be the introduction of frigorific particles into the pores or interſtices between the particles of water, and by that means getting ſo near them, as to be juſt within the ſpheres of one another's attractions, and then they muſt cohere into one ſolid or firm body.

It may be wondered why Ice goes to the top of the water, for one would imagine, that being colder than flowing water, it ought to be more condenſed, and conſequently heavier; but is to be conſidered, that there are always ſome bubbles of air interſperſed in Ice. It is certain, by the ſwimming of Ice upon water, that it is ſpecifically lighter than the water out of which it is made by freezing; and it is as certain, that this lightneſs of Ice proceeds from thoſe numerous bubbles that are produced in it by congelation.

Water, when it is frozen into Ice, takes up more ſpace than it did before it was congealed. It is viſible, that the dimenſions of water are increaſed by freezing, its particles being kept at ſome diſtance the one from the other, by the intervention of the frigorific matter.

And, beſides, there are many little volumes of air included at ſeveral diſtances, both in the pores of the watery particles, and in the interſtices made by the ſpherical figures. Now, by the inſinuation of theſe chryſtals, the volumes of air are driven out of the watery particles, and many of them uniting, form larger volumes; theſe have thereby a greater force to expand themſelves than when they are diſperſed, and ſo both enlarge their dimenſions, and leſſen the ſpecific gravity of water thus congealed into Ice.

It ſeems very probable, that cold, and freezing, and conſequently Ice, are produced by ſome ſubſtance of a ſaline nature floating in the air; in that ſalts, and more eminently ſome particular ones, when mixed with Ice or ſnow, do wonderfully increaſe the force and effects of cold.

It is alſo viſible, that all ſaline bodies cauſe a ſtiffneſs and frigidity in thoſe bodies into which they enter.

It is manifeſt, by obſerving ſalts by microſcopes, that the figures of ſome ſalts, before they ſhoot into maſſes, are then double wedge-like particles, which have abundance of ſurface in reſpect to their ſolidity; and this is the reaſon why they ſwim in water, when once they are raiſed in it, although they are ſpecifically heavier, theſe ſmall points of ſalts getting into the pores of the water, whereby they are, in ſome meaſure, ſuſpended in the winter, when the heat of the ſun is not ordinarily ſtrong enough to diſſolve the ſalts into fluid, to break their points, and to keep them in perpetual motion; which being leſs diſturbed, are more at liberty to approach one another, and by ſhooting into chryſtals, of the form above-mentioned, do, by their extremities, inſinuate themſelves into the pores of water, and by that means freeze it into a ſolid form, called Ice.

Monſ. Mariotte, in his Treatiſe of Hydroſtatics, gives the ſubſequent account of what happens to water in freezing, which he diſcovered by the following experiment.

Having filled a cylindric veſſel, of about ſeven or eight inches high, and ſix inches diameter, within two inches of the top, with cold water, he expoſed it to the open air in a great froſt, and obſerved exactly the whole progreſs of the freezing of it.

The firſt congelation was in the upper ſurface of the water, in little long water ſhoots, or laminæ, which were jagged like a ſaw, the water between them remaining ſtill unfrozen, though the reſt of the ſurface was already frozen to the thickneſs of more than two lines; he obſerved that ſeveral bubbles of air were formed in the Ice, that began to fix on the bottom and ſides of the veſſel, ſome would riſe up, and others remained entangled in the Ice, which made him imagine that theſe bubbles taking up more ſpace in the water, than when their matter was, as it were, diſſolved in it, they puſhed up a little water through the hole at the top, after the ſame manner that new wine works out at the bung-hole of a veſſel when it begins to heat, and the little water that ouzed out at this little hole in the Ice, ſpreading itſelf upon the upper ſurface of the water, which was already frozen, became Ice alſo, and there began to form a hill of Ice; and that hole continuing open, by reaſon of the water which paſſed ſucceſſively through it, being puſhed up by the new bubbles which formed themſelves in the Ice, which continue to increaſe about the ſides and bottom of the veſſel, he obſerved that the upper ſurface of the water was frozen above an inch thick towards the edges of the veſſel, and above an inch and a half round about the little hole, before the water that was contained in it, as in a pipe, became frozen, but at laſt it was frozen; then the middle of the water remaining unfrozen, and the water which was compreſſed by the new bubbles, which formed themſelves for two or three hours, having no vent at the little hole, the Ice broke at once towards the top, by the ſpring of the included air.

In like manner the froſt acts upon vegetables, by theſe frigorific particles entering the tender ſhoots of plants, and inſinuating between the pores of the ſap, thereby increaſing its bulk, ſo that the tender veſſels of the plants are torn, and thoſe parts of the plants are ſoon killed; and the greater the quantity of moiſture is in vegetables, the more they are in danger of being deſtroyed, for we frequently ſee many plants which grow on the top, and from the joints of walls, eſcape the ſevereſt froſts, when thoſe of the ſame kinds are all deſtroyed which were in the ground; which is entirely owing to their veſſels being ſtronger and more compact, and not ſo replete with moiſture: ſo when the autumn proves cold and moiſt, whereby the veſſels of plants are not properly hardened, and are replete with moiſture, a ſmall froſt will do great miſchief to them; whereas when the autumn is dry and warm, the tender ſhoots of trees and ſhrubs are hardened, and drained of their moiſture, ſo are not liable to the like accidents.

ICE-HOUSE is a building contrived to preſerve ice for the uſe of a family in the ſummer ſeaſon.

Theſe are more generally uſed in warm countries, than in England, but particularly in Italy, where the meaneſt perſon who rents a houſe, is not without a a vault or cellar for keeping of ice; but as the uſe of ice in England is much greater of late than it was formerly, ſo the number of Ice-houſes has been greatly increaſed; and although the mention of theſe may, at firſt ſight, ſeem foreign to my ſubject, yet if it is conſidered, that theſe buildings are generally erected in gardens, and as often put under the care of gardeners, it may not be amiſs for me to give ſome general directions for the choice of the ſituation and ſtructure of the building, as alſo for the management of the ice.

In the choice of a ſituation for an Ice-houſe, the principal regard ſhould be, that of a dry ſpot of ground, for wherever there is moiſture, the ice will melt; therefore in all ſtrong lands, which detain the wet, there cannot be too much care taken to make drains all round the building to carry off all moiſture; for when this is lodged near the building, it will occaſion a damp there, which will always be prejudicial to the keeping of the ice.

The next conſideration muſt be, to have the place ſo elevated, that there may be deſcent enough to carry off whatever wet may happen near the building, or from the ice melting; alſo, that the place be as much expoſed to the ſun and air as poſſible, and not placed under the drip, or in the ſhade of trees, as hath been too often practiſed, under a falſe notion, that if it ſhould be expoſed to the ſun, the ice will melt away in ſummer, which never can be the caſe where there is ſufficient care taken to exclude the outward air (which muſt always be regarded in the building of theſe houſes) for the heat of the ſun can never penetrate through the double arches of the building, ſo as to add any warmth to the air; but when the building is entirely open to the ſun and wind, all damps and vapours will thereby be removed from about the building, which can never be kept too dry, or free from moiſt vapours. As to the figure of the building, that may be according to the fancy of the owner; but for the well into which the ice is to be put, a circular figure is the moſt convenient; the depth of the well, as alſo the diameter of it, muſt be proportioned to the quantity of ice wanted, but it is always beſt to have enough; for when the houſe is well built, it will keep the ice for two or three years; and there will be this advantage in having it large enough to contain ice for two years conſumption, that if a mild winter ſhould happen, when there is not ice to be had, there will be a ſtock to ſupply the want.

If the quantity wanting is not great, a well of ſix feet diameter, and eight feet deep, will be large enough; but for large conſumption, it ſhould not be leſs than nine or ten feet diameter, and as many deep: where the ſituation is either dry chalk, gravel, or ſand, the pit may be entirely below the ſurface of the ground; but in ſtrong loam, clay, or moiſt ground, it will be the beſt way to raiſe it ſo high above the ſurface, as that there may be no danger from the wet.

At the bottom of the well there ſhould be a ſpace left, about two feet deep, to receive any moiſture which may drain from the ice, and a ſmall underground drain ſhould be laid from this, to carry off the wet; over this ſpace of two feet, ſhould be placed a ſtrong grate of wood, to let the moiſture fall down, which may at any time happen, from melting of the ice. The ſides of this well muſt be bricked up with a wall, at leaſt two bricks and a half thick; but if it is yet thicker, it will be better, becauſe the thicker the walls are made, the leſs danger there will be of the well being affected by any external cauſe. When the well is brought within three feet of the ſurface, there muſt be another outer arch or wall begun, which muſt be carried up to the height of the top of the intended arch of the well; and if there is a ſecond arch turned over from this well, it will add to the goodneſs of the houſe; but this muſt be ſubmitted to the perſon who builds, if he will be at the expence; but if not, then the plate into which the roof is to be framed, muſt be laid on this outer wall, which ſhould be carried high enough above the inner arch, to admit of a door-way in, to get out the ice. If the building is to be covered with ſlates or tiles, there ſhould be a thickneſs of Reeds laid under, to keep out the ſun and external air; if theſe Reeds are laid two feet thick, and plaſtered over with lime and hair, there will be no danger of the heat getting through it.

The external wall need not be built circular, but of any other figure, either ſquare, hexangular, or octangular; and where this ſtands much in ſight may be ſo contrived as to make it a good object. I have ſeen an Ice-houſe built in ſuch a manner as to have a handſome alcove ſeat in the front, and behind this ſeat was contrived a paſſage to get out and put in the ice; and by having the entrance behind, to the north aſpect, a ſmall paſſage being next the ſeat, through which a perſon might enter to take out the ice, and a large door being contrived with a porch, wide enough for a ſmall cart to back in, to ſhoot down the ice upon the floor near the mouth of the well, where it may be well broken, before it is put down. The aperture of this mouth of the well need not be more than two feet and a half diameter, which will be large enough to put down the ice, and if it was greater, it would be inconvenient; there ſhould be a ſtone fitted to ſtop this aperture, which muſt be cloſed up as ſecure as poſſible, after the ice is put in, and all the vacant ſpace above and between this and the outer door, muſt be filled cloſe with Barley Straw, to exclude the air; ſo the door to enter for taking out the ice ſhould be on the oppoſite ſide, immediately behind the alcove ſeat, as was before-mentioned; and this door ſhould be no larger than is abſolutely neceſſary for the coming at the ice, and muſt be ſtrong and cloſe to exclude the air; and at five or ſix feet diſtance from this another door ſhould be contrived, which ſhould be cloſely ſhut before the inner door is opened, whenever the ice is taken out.

The building being finiſhed, ſhould have time to dry before the ice is put into it; for when the walls are green, the damp of them frequently melts the ice. At the bottom of the well, upon the wooden grate, ſhould be laid ſome ſmall faggots; and if upon theſe a layer of Reeds is placed ſmooth for the ice to lie upon, it will be better than Straw, which is commonly uſed; and in the choice of the ice, the thinner it is, the better it may be broken to powder; for the ſmaller it is broken, the better it will unite when put into the well: in putting of it in, there muſt be care taken to ram it cloſe, as alſo to allow a vacancy all round next the wall, of about two inches; this is to give paſſage to any moiſture, which may be occaſioned by the melting of ſome of the ice on the top, which, if pent up, will melt the ice downward; when the ice is put into the well, if there is a little ſalt-petre mixed at every ten inches or a foot thickneſs, it will cauſe the ice to join more cloſely into a ſolid maſs. The inſtructions here given, being carefully obſerved, will be ſufficient to guide perſons wholly ignorant in theſe matters.

JET D'EAU is a French word, which ſignifies a fountain that caſts up water to any conſiderable height in the air.

Monſ. Mariotte, in his Treatiſe of Hydroſtatics, ſays, That a Jet d'Eau will never riſe ſo high as its reſervatory, but always falls ſhort of it by a ſpace which is in a ſubduplicate ratio of that height; and this he proves by ſeveral experiments; that though Jets ought to riſe to the height of the reſervatories, yet the friction of the ſides of the ajutages, and the reſiſtance of the air, are the cauſes that in Jets that have very high reſervatories, the height of the Jets does not come up to that of the reſervatory by a great deal.

He adds, That if a greater branches out in many ſmaller ones, or is diſtributed through ſeveral Jets, the ſquare of the diameter of the main pipe muſt be proportioned to the ſum of all the expences of its branches; that if the reſervatory be fifty-two high, and the ajutages half an inch in diameter, the pipe ought to be three inches in diameter.

He ſays, That the beauty of Jets of water conſiſts in their uniformity and tranſparency at the going out of the ajutage, and ſpreading but very little, and that to the higheſt part of the Jet.

That the worſt ſort of ajutages are thoſe that are cylindrical, for they retard very much the height of the Jets, the conic retard it leſs; but the beſt way is, to bore the horizontal plane, which ſhuts the extremity of the pipe, or conduit, with a ſmooth and poliſhed hole, taking care that the plate be perfectly plain, poliſhed, and uniform.

Theſe ſpouts of water are ſome of the greateſt beauties of the Italian gardens, and are certainly better adapted for gardens in thoſe warm countries, than they are for our climate, becauſe, in the great heats of ſummer, the ſight of theſe water-ſpouts is cooling and refreſhing to the imagination, and they certainly add a real coolneſs to the air; but in cold countries they cool the air too much, therefore ſhould not be erected; or if they are, they ſhould be placed at ſuch diſtances from the habitation, as that the damp may no ways affect it.

Where theſe Jets are contrived, if there is not a conſtant ſupply for a large column of water, they ſhould by no means be made, for nothing can have a meaner appearance, than thoſe pitiful piſſing ſpouts, ſo frequently to be ſeen in England, which perhaps have not a ſupply of water to play above an hour or two; therefore where there is not a natural body of water, to ſupply theſe Jets, without the expence of raiſing it, there ſhould never be any of theſe contrived in gardens.

ILEX. Lin. Gen. Plant. 158. Aquifolium. Tourn. Inſt. R. H. 600. tab. 371. The Holly-tree; in French, *Houx*.

The CHARACTERS are,

They have male, female, and hermaphrodite flowers on different plants. The male flowers have a ſmall permanent empalement of one leaf, which is indented in four parts; they have but one petal, which is cut into four ſegments almoſt to the bottom; they have four awl-ſhaped ſtamina, which are ſhorter than the petal, and are terminated by ſmall ſummits. The female flowers have their empalements and petals the ſame as the male, but have no ſtamina; in their center is placed the roundiſh germen, having four obtuſe ſtigmas ſitting on it. The germen afterward becomes a roundiſh berry with four cells, each containing a ſingle hard ſeed.

This genus of plants is ranged in the third ſection of Linnæus's fourth claſs, intitled Tetrandria Tetragynia, which includes thoſe plants whoſe flowers have four ſtamina and four ſtyles; but according to his own ſyſtem, it ſhould be placed in the third ſection of his twenty-ſecond claſs, with thoſe plants which have male and hermaphrodite flowers on different plants.

The SPECIES are,

1. ILEX (*Aquifolium*) foliis oblongo-ovatis, undulatis, ſpinis acutis. *Holly-tree with oblong leaves which are waved, and have acute ſpines.* Ilex aculeata baccifera. C. B. P. 425. *Prickly berry-bearing Ilex*; and the Aquifolium ſive agrifolium vulgò. J. B. 1. 114. *The common Holly.*
2. ILEX (*Echinata*) foliis ovatis, undulatis, marginibus aculeatis, paginis ſupernè ſpinoſis. *Holly with oval waved leaves, whoſe borders are armed with ſtrong thorns, and their upper ſurface prickly.* Aquifolium echinatâ folii ſuperfice. Cornut. Canad. 180. *Holly-tree whoſe upper ſurface of the leaves are prickly, commonly called Hedge-hog Holly.*
3. ILEX (*Caroliniana*) foliis ovato-lanceolatis ſerratis. Hort. Cliff. 40. *Holly with oval, ſpear-ſhaped, ſawed leaves.* Aquifolium Carolinienſe, foliis dentatis, baccis rubris. Cateſb. Carol. 1. p. 31. *Carolina Holly with indented leaves and red berries, commonly called Daboon Holly.*

There are ſeveral varieties of the common Holly with variegated leaves, which are propagated by the nurſery gardeners for ſale, and ſome years paſt were in very great eſteem, but at preſent are but little regarded, the old taſte of filling gardens with ſhorn Evergreens being pretty well aboliſhed; however, in the diſpoſition of the clumps or other plantations of Evergreen trees and ſhrubs, a few of the moſt lively colours may be admitted, which will have a good effect in the winter ſeaſon, if they are properly diſpoſed.

As the different variegations of the leaves of Hollies, are by the nurſery gardeners diſtinguiſhed by different titles, ſo I ſhall here mention the moſt beautiful of them, by the names they are generally known:

Painted Lady Holly, Britiſh Holly, Bradley's beſt Holly, Phyllis, or Cream Holly, Milkmaid Holly, Pritchet's beſt Holly, Gold-edged Hedge-hog Holly, Cheyney's Holly, Glory of the Weſt Holly, Broaderick's Holly, Partridge's Holly, Herefordſhire white Holly, Blind's Cream Holly, Longſtaff's Holly, Eales's Holly, Silver-edged Hedge-hog Holly.

All theſe varieties are propagated by budding or grafting them upon ſtocks of the common green Holly: there is alſo a variety of the common Holly with ſmooth leaves, but this is frequently found intermixed with the prickly-leaved on the ſame tree, and often on the ſame branch, there are both ſorts of leaves.

The common Holly grows naturally in woods and foreſts in many parts of England, where it riſes from twenty to thirty feet high, and ſometimes more, but their ordinary height is not above twenty-five feet. The ſtem by age becomes large, and is covered with a grayiſh ſmooth bark; and thoſe trees which are not lopped or browzed by cattle, are commonly furniſhed with branches the greateſt part of their length, ſo form a ſort of cone; the branches are garniſhed with oblong oval leaves about three inches long, and one and a half broad, of a lucid green on their upper ſurface, but are pale on their under, having a ſtrong midrib: the edges are indented and waved, with ſharp thorns terminating each of the points, ſo that ſome of the thorns are raiſed upward and others are bent downward, and being very ſtiff, renders them troubleſome to handle. The leaves are placed alternate on every ſide of the branches, and from the baſe of their footſtalks come out the flowers in cluſters, ſtanding on very ſhort foot-ſtalks; each of theſe ſuſtain five, ſix, or more flowers. In ſome plants I have obſerved the flowers were wholly male, and produced no berries; in others I have obſerved female and hermaphrodite flowers, but upon ſome large old trees growing on Windſor foreſt, I have obſerved all three upon the ſame trees. The flowers are of a dirty white, and appear in May; they are ſucceeded by roundiſh berries, which turn to a beautiful red about Michaelmas, but continue on the trees if they are not deſtroyed, till after Chriſtmas before they fall away.

The ſecond ſort grows naturally in Canada, from whence it was brought to Europe. The leaves of this ſort are not ſo long as thoſe of the common Holly, and their edges are armed with ſtronger thorns ſtanding cloſer together; the upper ſurface of the leaves is ſet very cloſe with ſhort prickles, from whence the gardeners have given it the title of Hedge-hog Holly. This ſort is uſually propagated in the nurſeries, by budding or grafting it upon the common Holly; but I have raiſed it from the berries, and found the plants to be the ſame as thoſe from whence the ſeeds were taken, ſo make no doubt of its being a diſtinct ſpecies.

There are two varieties of this with variegated leaves, one of which is yellow, and the other white. There is alſo a variety of the common Holly with yellow berries, which is alſo accidental, and is generally found on thoſe plants which have variegated leaves, and but ſeldom on plain Hollies.

The common Holly is a very beautiful tree in winter, therefore deſerves a place in all plantations of

Evergreen trees and ſhrubs, where its ſhining leaves and red berries make a fine variety; and if a few of the beſt variegated kinds are properly intermixed, they will enliven the ſcene. The Holly was alſo formerly planted for hedges, and is a very proper plant for that purpoſe; but then it ſhould not be clipped with ſhears, becauſe when the leaves are cut through the middle, they are rendered unſightly, ſo they ſhould be cut with a knife cloſe to the leaf; and although in this method they are not ſhorn ſo even as with ſhears, yet they will have a much better appearance, and may be made as cloſe and ſecure as by any other method generally practiſed.

The Holly is propagated by ſeeds, which never come up the firſt year, but lie in the ground as the Haws do; therefore the berries ſhould be buried in the ground in a large pot or tub one year, and then taken up and ſown in the autumn upon a bed expoſed only to the morning ſun; the following ſpring the plants will appear, which muſt be kept clean from weeds; and if the ſpring ſhould prove dry, it will be of great ſervice to the plants if they are watered once a week; but they muſt not have it oftener, nor in too great quantity, for too much moiſture is very injurious to theſe plants when young.

In this ſeed-bed the plants may remain two years, and then ſhould be tranſplanted in the autumn, into beds at about ſix inches diſtance each way, where they may ſtand two years longer, during which time they muſt be conſtantly kept clean from weeds; and if the plants have thriven well, they will be ſtrong enough to tranſplant where they are deſigned to remain; for when they are tranſplanted at that age, there will be leſs danger of their failing, and they will grow to a larger ſize than thoſe which are removed when they are much larger; but if the ground is not ready to receive them at that time, they ſhould be tranſplanted into a nurſery in rows at two feet diſtance, and one foot aſunder in the rows, in which place the plants may remain two years longer; and if they are deſigned to be grafted or budded with any of the variegated kinds, that ſhould be performed after the plants have grown one year in this nurſery; but the plants ſo budded or grafted ſhould continue two years after in the nurſery, that they may make good ſhoots before they are removed; though the plain ones ſhould not ſtand longer than two years in the nurſery, becauſe when they are older, they do not tranſplant ſo well. The beſt time for removing of Hollies is in the autumn, eſpecially in dry land; but where the ſoil is cold or moiſt, they may be tranſplanted with great ſafety in the ſpring; if the plants are not too old, or if they have not ſtood long unremoved, there is great odds of their dying when removed.

The Dahoon Holly grows naturally in Carolina, from whence the ſeeds were ſent by the late Mr. Mark Cateſby, who found the trees growing on a ſwamp at a diſtance from Charles-town, but it hath ſince been diſcovered in ſome other countries in North America. This riſes with an upright branching ſtem to the height of eighteen or twenty feet; the bark of the old ſtems is of a brown colour, but that of the branches or younger ſtalks is green and ſmooth, garniſhed with ſpear-ſhaped leaves, which are more than four inches long, and one and a quarter broad in the broadeſt part, of a light green and thick conſiſtence; the upper part of the leaves are ſawed on their edges, each ſerrature ending in a ſmall ſharp ſpine; they ſtand alternately on every ſide the branches, upon very ſhort foot-ſtalks. The flowers come out in thick cluſters from the ſide of the ſtalks; they are white, and ſhaped like thoſe of the common Holly, but are ſmaller; the female and hermaphrodite flowers are ſucceeded by ſmall roundiſh berries in its native country, which make a fine appearance in winter, but they have not as yet produced fruit in England, ſo far as I can learn.

Dr. Linnæus ſuppoſes this plant and the evergreen Caſſine to be the ſame, but they are undoubtedly diſtinct plants: he may probably have been led into this miſtake, by receiving ſeeds of this ſort mixed together with the berries of Caſſine from America, which I have more than once done; but whoever ſees the two plants growing, cannot doubt of their being different.

This ſort is tender while young, ſo requires protection in the winter till the plants are grown ſtrong and woody, when they may be planted in the full ground in a warm ſituation, where they will endure the cold of our ordinary winters pretty well; but in ſevere froſt they ſhould be protected, otherwiſe the cold will deſtroy them.

This ſort is propagated from ſeeds, in like manner as the common ſort; the ſeeds of it will lie as long in the ground, ſo the berries ſhould be buried in the ground a year, and then taken up and ſown in pots filled with light earth, and placed under a frame in winter; in the ſpring the pots ſhould be plunged into a hot-bed, which will bring up the plants; theſe muſt be preſerved in the pots while young, and ſheltered in winter under a common frame till they have obtained ſtrength, when in the ſpring they may be turned out of the pots and planted in the full ground, in a warm ſituation.

From the bark of the common Holly is made the bird-lime, and the wood is made into hones for ſetting of razors. The wood is very white, and takes a fine poliſh, ſo is very proper for ſeveral kinds of furniture. I have ſeen a floor of a room laid in compartments with Holly and Mahogany, which had a very pretty effect.

ILLECEBRUM. Lin. Gen. 291. Corrigiola. Dill. Gen. p. 169. Paronychia. Tourn. Inſt. 281.

The CHARACTERS are,

It hath a five-cornered coloured empalement of five leaves, which is permanent, but has no petals; it hath five ſlender ſtamina within the empalement, terminated by ſimple ſummits, and an oval germen with a ſhort ſtyle, crowned by an obtuſe ſtigma. The empalement afterward becomes a roundiſh capſule with five angles, having one cell, containing one large ſeed, which is pointed on every ſide.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, the flowers having five ſtamina and one ſtyle.

The SPECIES are,

1. ILLECEBRUM (*Suffruticoſum*) floribus lateralibus ſolitariis, caulibus ſuffruticoſus. Lin. Sp. 298. *Illecebrum with an under-ſhrub ſtalk, having ſingle flowers on the ſides.* Paronychia Hiſpanica fruticoſa, myrti folio. Tourn. Inſt. 508.
2. ILLECEBRUM (*Paronychia*) floribus bracteis nitidis obvalatis, caulibus procumbentibus. Lin. Sp. 299. *Illecebrum with neat bractea incloſing the flowers, and trailing ſtalks.* Paronychia Hiſpanica. Cluſ. Hiſt. 2. p. 183.
3. ILLECEBRUM (*Capitatum*) floribus bracteis nitidis occultantibus capitula terminalia, caulibus erectis, foliis ciliatis. Lin. Sp. 299. *Illecebrum with neat bractea terminating the erect ſtalks, and ſilvery leaves.* Paronychia Narbonenſis erecta. Tourn. Inſt. 508.
4. ILLECEBRUM (*Achyrantha*) caulibus repentibus piloſis, foliis ovatis mucronatis oppoſito minore, capitulis ſubgloboſis ſubſpinoſis. Lin. Sp. 299. *Illecebrum with creeping ſtalks, ſmall oval-pointed leaves placed oppoſite, almoſt globular heads of flowers, having ſmall ſpines.* Achyrantha repens, foliis bliti pallidi. Hort. Elth. 8. tab. 7.
5. ILLECEBRUM (*Polygonoides*) caulibus repentibus hirtis, foliis lato-lanceolatis petiolatis, capitulis orbiculatis nudis. Lin. Sp. 300. *Illecebrum with hairy creeping ſtalks, broad ſpear-ſhaped leaves on foot-ſtalks, and orbicular naked heads of flowers.* Amaranthoides humile Curaſſavicum, foliis polygoni. Herm. Parad. 17.
6. ILLECEBRUM (*Vermiculatum*) caulibus repentibus glabris foliis, ſubteretibus carnoſis, capitulis oblongis glabris terminalibus. Lin. Sp. 300. *Illecebrum with ſmooth creeping ſtalks, almoſt taper fleſhy leaves, and oblong ſmooth heads terminating the branches.* Amaranthoides humile Curaſſavicum, cepeæ foliis lucidis, capitulis. Herm. Parad. 15.

The three firſt ſorts grow naturally in Spain, Portugal, and the ſouth of France; the firſt has ligneous ſtalks about a foot high, garniſhed with ſmall leaves like thoſe of Knot-graſs; the flowers come out ſingly on the ſide of the ſtalks, which make little appearance, ſo is ſeldom preſerved in gardens.

The ſecond and third ſorts have trailing ſtalks near two feet long, which ſpread on the ground, garniſhed with leaves like thoſe of the firſt ſort; the heads of flowers come out from the joints of the ſtalk, having neat ſilvery bractea ſurrounding them, which make a pretty appearance. Their flowers appear in June, and there is generally a ſucceſſion of them for at leaſt two months; and when the autumn proves warm, they will ripen their ſeeds the beginning of October.

Theſe three ſorts may be propagated by ſeeds, which ſhould be ſown on a bed of light earth the beginning of April; the plants will come up in May, when they ſhould be kept clean from weeds till the plants are fit to remove; then the plants ſhould be carefully taken up, planting ſome of each ſort in ſmall pots, and the other into a warm dry border, obſerving to water and ſhade them until they have taken new root; after which, thoſe which are planted in the full ground will require no other culture but to keep them clean from weeds; for in the ordinary winters of England, they will live in the open air: but as theſe plants are ſometimes killed in ſevere winters, therefore I adviſe ſome plants to be planted in pots, which may be placed in a common frame in winter, where they may enjoy the open air in mild weather, but be ſcreened from froſt.

As the ſeeds of theſe plants do not conſtantly ripen in England, ſo they may be propagated by cuttings, which, if carefully taken off in May or June, and planted in a ſhady border, will in two months put out roots; then in moiſt weather they may be tranſplanted, and afterward treated as the old plants.

The other three ſorts are natives of the warm parts of America; the fourth ſort grows naturally at Beunos Ayres; the fifth and ſixth, in many of the iſlands in the Weſt-Indies.

Theſe have creeping ſtalks, which ſend out roots from the joints, which faſten to the ground in their native ſoil, whereby they ſpread to a great diſtance; and in this country, when the pots are plunged into a tan-bed, they will multiply as faſt, by taking root in tan, or any of the other pots of plants which are near them.

The flowers of the fourth ſort make little appearance, therefore the plant is rarely propagated, except in botanic gardens for variety; but thoſe of the fifth and ſixth ſort have dry heads of flowers, reſembling thoſe of the Amaranthoides, under which genus they were formerly ranged.

Theſe three ſorts are tender, ſo will not thrive in the open air in England; therefore their ſeeds ſhould be ſown on a hot-bed in the ſpring, at the ſame time as the Amaranthus, Gomphrena, and other tender plants; and afterward, if they are plunged into the tan-bed in the ſtove, their branches will put out roots, whereby they may be propagated in plenty.

IMPATIENS. Rivin. Ord. 4. Lin. Gen. Plant. 899. Balſamina. Tourn. Inſt. R. H. 418. tab. 235. Female Balſamine; in French, *Balſamine*.

The Characters are,

The flower has a two-leaved ſmall empalement, which is coloured, and placed on the ſide of the petals. It hath five petals which are unequal, and ſhaped like a lip-flower; the petals are roundiſh, the upper is erect, ſlightly cut at the point into three parts, where it is ſharp-pointed, forming the upper lip; the two lower petals are broad, obtuſe, irregular, and reflexed; theſe conſtitute the lower lip; the intermediate pair are alike, and are placed oppoſite, joining at their baſe. It hath a nectarium in the bottom of the flower, ſhaped like a hood or cowl, which is oblique to the mouth, riſing on the outſide, whoſe baſe ends in a tail or ſpur. It hath five ſhort ſtamina which are narrow toward their baſe, and incurved, terminated by ſummits, which join at the top round the ſtamina, but are divided at their baſe. In the bottom is ſituated an oval ſharp-pointed germen, having no ſtyle, but a ſingle ſtigma ſhorter than the ſummits. The germen afterward becomes a capſule with one cell, opening with an elaſticity in five valves, which twiſt ſpirally, and contain ſeveral roundiſh ſeeds fixed to a column.

This genus of plants is ranged in the fifth ſection of Linnæus's nineteenth claſs, which includes thoſe plants which have ſingle flowers in the empalement, whoſe ſtamina vary in number and ſituation.

The Species are,

1. Impatiens (*Noli tangere*) pedunculis multifloris ſolitariis, foliis ovatis, geniculis caulinus tumentibus. Flor. Suec. 722. *Impatiens with foot-ſtalks ſuſtaining many ſingle flowers, oval leaves, and ſtalks having ſwelling joints.* Balſamina lutea, ſive, Noli me tangere. C. B. P. 306. *Yellow Balſamine, or Touch me not.*
2. Impatiens (*Balſamina*) pedunculis unifloris aggregatis, foliis lanceolatis, nectaris floribus brevioribus. Hort. Upſal. 276. *Impatiens with foot-ſtalks ſuſtaining ſingle flowers, which ariſe in cluſters, ſpear-ſhaped leaves, and nectariums which are ſhorter than the flower.* Balſamina fœmina. C. B. P. 306. *The female Balſamine.*
3. Impatiens (*Triflora*) pedunculis trifloris ſolitariis, foliis anguſto-lanceolatis. Flor. Zeyl. 315. *Impatiens with three flowers on a foot-ſtalk, and narrow ſpear-ſhaped leaves.* Balſamina erecta, ſc. fœmina, Perſicæ anguſto folio Zeylanica. Herm. Par. Bat. 105. *Upright, or female Balſamine of Ceylon, with a narrow Peach leaf.*

There are ſeveral other ſpecies of this genus, which grow naturally in India, which are plants of little beauty, ſo have not been introduced into the Engliſh gardens; the ſorts here mentioned, are all I have yet ſeen growing here, except one tall ſort from North America.

The firſt ſort grows naturally in ſeveral parts of Weſtmoreland and Yorkſhire, but is frequently introduced into gardens by way of curioſity. It is an annual plant, which riſes about a foot and a half high, with an upright ſucculent ſtalk, whoſe joints are ſwollen, garniſhed with oval ſmooth leaves, which ſtand alternate on every ſide the ſtalk. The flowers come out from the wings of the ſtalks upon long ſlender foot-ſtalks, which branch into ſeveral other ſmaller, each ſuſtaining one yellow flower, compoſed of five petals, which in front are ſhaped like the lip or grinning flowers, but at their baſe have a nectarium with a long tail like the flowers of Indian Creſs; theſe are ſucceeded by taper pods, which, when ripe, burſt open upon being touched, and twiſt ſpirally like a ſcrew, caſting out the ſeeds with great elaſticity. If the ſeeds of this plant are permitted to ſcatter, they generally ſucceed better than when they are ſown; for unleſs they are ſown in the autumn ſoon after they are ripe, they very rarely grow. The plants require no care but to keep them clean from weeds, and thin them where they are too cloſe. It flowers in June, and the ſeeds ripen about a month or five weeks after; this delights in a ſhady ſituation and a moiſt ſoil.

The ſecond ſort is the female Balſamine, of which there are ſeveral varieties; the common ſort has been long an inhabitant in the Engliſh gardens, of this there is the white, the red, and ſtriped flowered, and likewiſe the ſingle and double flowering, with variegated flowers of two colours. Theſe ſorts are ſo hardy as to riſe in the full ground; and where the ſeeds ſcatter, the plants will come up the following ſpring; but ſuch ſelf-ſown plants do not come to flower ſo early as thoſe which are raiſed upon a hot-bed; however, they generally are ſtronger plants, and continue much longer in the autumn in flower than the others, ſo are an ornament to the garden, when there is a greater ſcarcity of flowers.

This ſort riſes a foot and a half high, dividing into many ſucculent branches, which are garniſhed with long, ſpear-ſhaped, ſawed leaves. The flowers come out from the joints of the ſtalks, upon ſlender foot-ſtalks about an inch long, each ſuſtaining a ſingle flower; but there are two, three, or four of theſe foot-ſtalks ariſing from the ſame joint. The flowers are compoſed of five large unequal petals, which are ſhaped like thoſe of the former ſort, but are larger, and ſpread open much wider; there are white, purple, and red of this ſort, as alſo ſingle and double flowers. If the ſeeds of theſe are ſown on a moderate hot-bed in the ſpring, the plants will flower in June; but thoſe which are ſown in the full ground, will not flower before the middle of July; and theſe will continue flowering till the froſt puts a ſtop to them in the autumn.

There are two other varieties of this, if not diſtinct ſpecies; one of them grows naturally in the Eaſt, and the other in the Weſt-Indies; that which comes from the Eaſt-Indies, by the title of Immortal Eagle Flower, is a moſt beautiful plant; the flowers are double, much larger than thoſe of the common ſort; they are ſcarlet and white variegated, and purple and white in others; and the plants producing many flowers, render them very valuable; and if the ſeeds of theſe are carefully ſaved, the kinds may always be preſerved; but I have raiſed ſome plants from foreign ſeeds, whoſe flowers were ſo very double as to loſe their male parts, ſo did not produce any ſeeds.

The ſeeds of theſe plants ſhould be ſown on a moderate hot-bed in the ſpring, and when the plants are come up about an inch high, they ſhould be tranſplanted on another moderate hot-bed at about four inches diſtance each way, obſerving to ſhade them from the ſun till they have taken new root; after which they ſhould have a large ſhare of free air admitted to them, at all times when the weather is favourable, to prevent their drawing up tall and weak: they will require to be often refreſhed with water, but it ſhould not be given to them in too great plenty; for as their ſtems are very ſucculent, ſo they are apt to rot with much moiſture. When the plants are grown ſo large as to touch each other, they ſhould be carefully taken up with balls of earth to their roots, and each planted into a ſeparate pot filled with light rich earth, and plunged into a very moderate hod-bed under a deep frame, to admit the plants to grow, ſhading them from the ſun until they have taken freſh root; then they ſhould have a large ſhare of air admitted to them every day, and by degrees hardened, ſo as to bear the open air, into which part of the plants may be removed in July, placing them in a warm ſheltered ſituation; where, if the ſeaſon proves favourable, they will flower and make a fine appearance; but it will be proper to keep part of the plants either in a glaſs-caſe or a deep frame, in order to get good ſeeds, becauſe thoſe in the open air will not ripen their ſeeds unleſs the ſummer proves very warm; and the plants in ſhelter muſt have a good ſhare of free air every day, otherwiſe they will grow pale and ſickly; nor ſhould they have too much of the ſun in the middle of the day, in very hot weather, for that occaſions their leaves hanging and their requiring water, which is often very hurtful; therefore if the glaſſes are ſhaded in the middle of the day for three or four hours, the plants will thrive better, and continue longer in beauty than when they are expoſed to the great heat. Thoſe who are curious to preſerve theſe plants in perfection, pull off all the ſingle and plain coloured flowers from the plants which they preſerve for ſeeds, leaving only thoſe flowers which are double and of good colours; where this is carefully done, they may be continued without the leaſt degeneracy conſtantly.

The ſort which grows in the Weſt-Indies, is there called Cockſpur. This hath ſingle flowers as large as the laſt-mentioned ſort, but I never ſaw any of them more than half double, and only with white and red ſtripes: the plants are very apt to grow to a very large ſize before they produce any flowers, ſo that it is late in the autumn before they begin to flower; and ſometimes in bad ſeaſons they will ſcarce have any flowers, and but rarely ripen their ſeeds here, ſo that few perſons care to cultivate this ſort, eſpecially if they can have the other.

The third ſort here mentioned grows naturally in Ceylon, and in many parts of India; this hath very narrow ſpear-ſhaped leaves, which are ſawed on their edges; the foot-ſtalks ſuſtain each three flowers, which are ſmaller than thoſe of the common ſort, ſo are not worthy of a place in gardens, except for the ſake of variety. This is a tender plant, and requires the ſame treatment as the Immortal Eagle Flower.

IMPERATORIA. Lin. Gen. Plant. 321. Tourn. Inſt. R. H. 316. tab. 168. Maſterwort; in French, *Imperatoire.*

The Characters are,

It hath an umbellated flower; the principal umbel is plain, and compoſed of many ſmaller; the greater umbel has no involucrum, but the ſmall ones have, which are compoſed of many narrow leaves, almoſt as long as the umbel; the principal umbel is uniform; the flowers have five heart-ſhaped petals, which are equal and inflexed. They have five hairy ſtamina, terminated by roundiſh ſummits. The germen is ſituated under the petals, ſupporting two reflexed ſtyles, crowned by obtuſe ſtigmas. The germen afterward becomes a roundiſh compreſſed fruit divided in two parts, containing two oval-bordered ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's fifth claſs, intitled Pentandria Digynia, which contains the plants whoſe flowers have five ſtamina and two ſtyles.

We have but one Species of this genus, viz.

Imperatoria (*Oſtruthium.*) Hort. Cliff. 103. *Maſterwort.* Imperatoria major. C. B. P. 156. *Greater Maſterwort*; and the Aſtrantia of Dodonæus. Pempt. 320. *Maſterwort, or falſe Pellitory of Spain.*

This plant grows naturally on the Auſtrian and Styrian Alps, and upon other mountainous places in Italy; the root is as thick as a man's thumb, running obliquely in the ground; it is fleſhy, aromatic, and has a ſtrong acrid taſte, biting the tongue and mouth like Pellitory of Spain; the leaves ariſe immediately from the root; they have foot-ſtalks ſeven or eight inches long, dividing into three very ſhort ones at the top, each ſuſtaining a trilobate leaf, indented on the border; the foot-ſtalks are deeply channelled, and when broken emit a rank odour. The flower-ſtalks riſe about two feet high, and divide into two or three branches, each being terminated by a pretty large umbel of white flowers, whoſe petals are ſplit; theſe are ſucceeded by oval compreſſed ſeeds, ſomewhat like thoſe of Dill, but larger. It flowers in June, and the ſeeds ripen in Auguſt.

This plant is cultivated in gardens to ſupply the markets. It may be propagated either by ſeeds, or by parting the roots: if you would propagate it by ſeeds, they ſhould be ſown in autumn ſoon after they are ripe, on a bed or border, in a ſhady ſituation; obſerving not to ſow the ſeeds too thick, nor ſhould they be covered too deep. In the ſpring the plants will appear, when they ſhould be carefully weeded; and if the ſeaſon ſhould prove very dry, they ſhould be now and then refreſhed with water, which will greatly promote their growth. Toward the beginning of May, if you find the plants come up too cloſe together, you ſhould prepare a moiſt ſhady border (and thin the plants carefully, leaving them about ſix inches aſunder;) and plant thoſe which you draw up into the border about the ſame diſtance apart every way, being careful to water them duly, if the ſeaſon ſhould prove dry, until they have taken root; after which time, theſe plants (as alſo thoſe remaining in the ſeed-beds) will require no other culture but to keep them clear from weeds; which may be eaſily effected, by hoeing the ground between the plants now and then in dry weather, which will deſtroy the weeds; and by thus ſtirring the ground, will be of great ſervice to the plants. The following autumn theſe plants ſhould be tranſplanted where they are deſigned to remain, which ſhould be in a rich moiſt ſoil and a ſhady ſituation;

tation; where they will thrive much better than if too much expoſed to the ſun, or in a dry ſoil, for they delight in ſhade and moiſture; ſo that where theſe are wanting the plants will require a conſtant ſupply of water in dry weather, otherwiſe they will thrive but ſlowly. The diſtance which theſe plants ſhould be placed, muſt not be leſs than two feet every way, for where they like their ſituation, they will ſpread and increaſe much. When theſe plants are rooted, they will require no other culture but to keep them clear from weeds; and in the ſpring, before they ſhoot, the ground ſhould be every year gently dug between the plants; in doing of which, great care ſhould be had not to cut or bruiſe their roots. Theſe plants, with this management, will continue ſeveral years, and will produce ſeeds in plenty.

If you would propagate theſe plants by offſets, their roots ſhould be parted at Michaelmas, and planted in a ſhady ſituation, at the ſame diſtance as has been directed for the ſeedling plants, obſerving to water them until they have taken root, after which time they muſt be managed as the ſeedlings.

The roots of this plant are uſed in medicine, and are greatly reccommended for their virtue in contagious diſtempers, or the bites of venomous creatures; they are alexipharmic and ſudorific; by ſome they are recommended for cholics and aſthmas, for the cramp, and all cold diſeaſes of the nerves.

INARCHING is a method of grafting, which is commonly called grafting by approach. This method of grafting is uſed when the ſtock you intend to graft on, and the tree from which you would take the graft ſtand ſo near (or can be brought ſo near) that they may be joined together. The method of performing it is as follows: take the branch you would Inarch, and having fitted it to that part of the ſtock where you intend to join it, pare away the rind and wood on one ſide about three inches in length. After the ſame manner cut the ſtock or branch in the place where the graft is to be united, ſo that the rind of both may join equally together, at leaſt on one ſide, that the ſap may meet; then cut a little tongue upwards in the graft, and make a notch or ſlit in the ſtock downward to admit it; ſo that when they are joined, the tongues will prevent their ſlipping, and the graft will more cloſely unite with the ſtock. Having thus placed them exactly together, you muſt tie them with ſome baſs, or other ſoft bandage; then cover the place with grafting clay, to prevent the air from entering to dry the wound, or the wet from getting in to rot the ſtock: you ſhould alſo fix a ſtake into the ground to which that part of the ſtock, as alſo the graft ſhould be faſtened, to prevent the wind from breaking them aſunder, which is often the caſe when this precaution is not obſerved.

In this manner they are to remain about four months, in which time they will be ſufficiently united, and the graft may then be cut from the mother tree, obſerving to ſlope it off cloſe to the ſtock; and if at this time you cover the joined parts with freſh grafting clay, it will be of great ſervice to the graft.

This operation is always performed in April or May, that the graft may unite with the ſtock before the ſucceeding winter, and is commonly practiſed upon Oranges, Myrtles, Jaſmines, Walnuts, Firs, Pines, and ſeveral other trees, which will not ſucceed ſo well by common grafting or budding. But although I have mentioned Orange-trees among the reſt, yet I would by no means adviſe this practice where the trees are deſigned to grow large, which, in this method, they rarely ever will do; and it is chiefly practiſed upon thoſe trees only as a curioſity, to have a young plant with fruit upon it, in a year or two from ſeed, by Inarching a bearing branch into a young ſtock, whereby it is effected, yet theſe plants are ſeldom long lived.

INDIGOFERA. Lin. Gen. 889. Indigo.

The Characters are,

The empalement is of one leaf, ſpreading almoſt flat, and cut into five ſegments; the flower is of the butterfly kind, having a roundiſh ſpreading ſtandard, which is indented at the point and reflexed: the wings are oblong, obtuſe, and their under borders ſpreading; the keel is obtuſe, ſpreading, and acute-pointed. It hath ten ſtamina digeſted in a cylinder whoſe points aſcend, terminated by roundiſh ſummits, and a cylindrical germen, ſupporting a ſhort ſtyle, crowned by an obtuſe ſtigma. The germen afterward becomes a long taper pod, incloſing kidney-ſhaped ſeeds.

This genus of plants is ranged in the third ſection of Linnæus's ſeventeenth claſs, intitled Diadelphia Decandria, from the flowers having ten ſtamina formed in two bodies.

The Species are,

1. Indigofera (*Tinctoria*) leguminibus arcuatis incanis, racemis folio brevioribus. Flor. Zeyl. 273. *Indigo with hoary arched pods, and the bunches of flowers ſhorter than the leaves.* Anil ſive Indigo Americana, ſiliquis in falculæ modum contortis. Acad. R. Scien. 1718. *Guatimala Indigo.*
2. Indigofera (*Suffruticoſa*) leguminibus arcuatis incanis, caule fruticoſa. *Indigo with a ſhrubby ſtalk, and hoary arched pods.* Colutea affinis fruticoſa argentea, floribus ſpicatis è viride purpureis, ſiliquis falcatis. Sloan. Cat. Jam. 142.
3. Indigofera (*Caroliniana*) leguminibus teretibus, foliolis quinis ſpicis longiſſimis ſparſis, radice perenne. *Indigo with taper pods, leaves with five lobes, long looſe ſpikes of flowers, and a perennial root.*
4. Indigofera (*Indica*) leguminibus pendulis lanatis compreſſis, foliis pinnatis. *Indigo with woolly, compreſſed, hanging pods, and winged leaves.*
5. Indigofera (*Glabra*) leguminibus glabris teretibus, foliolis trifoliatis. *Indigo with ſmooth taper pods, and trifoliate leaves.*

The firſt and fifth ſorts are annual plants with us; the ſeeds of theſe muſt be ſown on a hot-bed early in the ſpring of the year, and when the plants are come up two inches high, they ſhould be tranſplanted into ſmall pots filled with good freſh earth, and the pots plunged into a hot-bed of tanners bark; when the plants have obtained ſome ſtrength, they muſt have a great ſhare of free air, by raiſing the glaſſes in the day time; and in June they may be expoſed more to the open air, by which time they will begin to produce their flowers, which will be ſucceeded by pods in a ſhort time after, and in Auguſt their ſeeds will be perfected, if the plants are brought forward in the ſpring.

The ſecond ſort grows to the height of five or ſix feet, and will abide two or three years, if it is preſerved in a very warm ſtove in winter; this produces ſpikes of flowers from the wings of the leaves on the ſides of the ſtems of the plant, and ſometimes will perfect its ſeeds in England. This muſt be raiſed in a hot-bed, as was directed for the two former, but muſt not be wholly expoſed to the open air, even in the hotteſt weather.

The fourth ſort is ſuppoſed to be promiſcuouſly uſed to make the Indigo, but the firſt is the common ſort which is cultivated in the Engliſh plantations in America; but I have been aſſured by a perſon of great credit, that he has made as good Indigo from the ſecond ſort, as any that was produced in our plantations; and this being a much larger plant, will afford a greater quantity from the ſame compaſs of ground, than any one of the other ſpecies, eſpecially if cut before the ſtalks grow ligneous; and this ſort will grow on poorer land, ſo may be cultivated in ſuch places where the firſt ſort will not thrive ſo well, by which means great improvements may be made with this plant in our American plantations. There are ſome other ſorts of this plant which are natives of India, from which this commodity is made; two of which, viz. the fourth and fifth ſorts I have had growing in the garden at Chelſea, both which are very different in their leaves and pods from either of the American ſorts which have been cultivated. I have alſo received ſeeds from India of the third ſort, which is the ſame ſpecies of Indigo which grows naturally in South Carolina, and which was greatly eſteemed ſome years ago by the Indigo planters of that country, for the beauty of the commodity which it produced; but the plants being ſlender and thinly garniſhed with leaves, which were ſmall, they did not furniſh a quantity of Indigo in proportion to their bulk, ſo of late this ſort has not been much cultivated there; though the account which I received with the ſeeds was, that it was what the beſt Indigo of India was made from.

The whole proceſs in making the Indigo being exactly deſcribed by Pere Labat in his voyages, I thought it would not be unacceptable to the Engliſh reader, to tranſlate his account in this place, which is as follows:

There was formerly a great deal of Indigo made in the pariſh of Macauba: there is not a ſtream nor river in it, where one does not meet with Indigo works, that is, backs or vats of ſtone-work well cemented, in which the plant that yields the dye is put to digeſt: there are uſually three of theſe vats one above another, in the manner of a caſcade; ſo that the ſecond, which is lower than the bottom of the firſt, may receive the liquor contained in the firſt, when the holes which are made in the bottom of the firſt are unſtopped; and that the third may in its turn receive what was in the ſecond.

The firſt, largeſt, and higheſt of theſe vats is called the ſteeper or rot; it is uſually made twenty feet long, twelve or fifteen feet wide, and three or four feet deep. The ſecond is called the battery, it is almoſt half as ſmall again as the firſt: and the third, which is much leſs than the ſecond, is called the devilling.

The names of the two firſt perfectly agree with their uſes, for the plant is laid to ſteep in the firſt, where it ferments, is macerated, and becomes like rotten dung: after that the ſalts and ſubſtance of the leaf and rind are diffuſed in the water by the fermentation, which the heat and ripeneſs of the plant has excited in it. It is in the ſecond that they agitate and beat this water, impregnated and loaded with the ſalts of the plant, till having collected, re-united, and, as it were, coagulated them with one another, they form the particles which compoſe the dye.

As for the name of the third, I do not ſee how it agrees with it, unleſs it be becauſe this vat is deeper coloured than the others; for the Indigo already formed remaining in it, conſequently dyes and colours it much deeper than the others.

To which I ſhould add, that it is only at St. Domingo that they make uſe of this name. In the Windward Iſlands they call this laſt vat the ſettler, and this name ſuits it perfectly well, becauſe it is in this, that the Indigo begun in the ſteeper, and perfected in the battery unites, grows into a maſs, ſeparates itſelf from the particles of water which remained in it, leaves them at top, and ſettles at the bottom of the vat; whence it is taken out to be put into little bags, and then into the boxes, as I ſhall mention hereafter.

Nothing ought to be omitted in the building and making theſe vats ſubſtantial; the ſtrength of the fermentation is ſo great, that unleſs the ſtone-work and plaſter be very well done, and the mortar carefully choſen and wrought, they crack; and a very moderate crack is ſufficient to let out a vat of Indigo, and cauſe a conſiderable loſs to the owner.

When this misfortune happens, the following is an eaſy and infallible remedy, which I can anſwer for, as having experienced it. Take ſome ſea ſhells of any kind whatever, pound them without burning them, powder them, and ſift them through a fine ſieve. Take an equal quantity of quick lime and ſift it; mix theſe together with water enough to make a ſtiff mortar, and as quick as you can, ſtop the cracks of your vats with it. This mixture incorporates, ſticks, and dries in a moment, and immediately prevents the matter's running out of the vat.

Every body does, or ſhould know, that Indigo is a dye uſed to dye wool, ſilk, cloths, and ſtuffs, blue: the Spaniards call it Anilo: the fineſt they make, i. e. in New Spain, comes from Guatimala, which makes a great many people call it barely Guatimalo. It is made alſo in the Eaſt-Indies, particularly in the dominions of the Great Mogul, the kingdom of Golconda, and other places thereabouts, as Mr. Tavernier relates in his voyages. This ſort is in Europe oftener called India than Indigo or Anil, people taking for its proper name the name of the place it was made at. Some authors, and among others, Father du Tertre of our order, having fancied that the Indigo which comes from the Eaſt-Indies is more beautiful, finer, and dearer, than that which comes from the Weſt-Indies, which they call flat Indigo, while they call that from the Eaſt barely India. They would have ſpoken more properly, if they had called the latter round India; for, by their leave, all the difference between the two Indias, or Indigos, is, that that made in the Eaſt-Indies is ſhaped like half eggs, and that of the Weſt like cakes; for as for goodneſs and beauty, the one will not be a whit ſuperior to the other, if both are wrought with equal care and fidelity.

The ſhape of the Oriental Indigo obliges the merchants who would carry it into Europe to pound it, that they may put the more into the cheſts, or barrels they put it up in. It is certain, that being thus pounded, its grain having been broken under the peſtle, ground, and reduced to powder, makes it finer than the Weſt-Indian Indigo, which coming in cakes juſt as it was dried, ſhews its grain entire, and conſequently muſt appear coarſer; but what is that to the intrinſic goodneſs of the commodity; I maintain it is the ſame in both, though there ſeems to be a difference.

To be convinced of this truth, take a lump of ſugar equally white throughout, break it in two, pound one part of it, and reduce it to powder; this will look finer and whiter than that which is whole, which proceeds only from this, that the grain of the one has been ſeparated and divided into a greater number of parts, which, though very ſmall, and almoſt inſenſible, yet have a greater number of ſurfaces, and conſequently reflect more light; whereas the other remaining entire, preſenting to the ſight only a large grain, which has but little ſurface, of courſe reflects leſs light, and by a neceſſary conſequence muſt appear leſs white; which is the ſame as appearing leſs beautiful, ſince the beauty of ſugar conſiſts in its whiteneſs. Methinks we may reaſon in the ſame manner upon Indigo, and ſay, that cæteris paribus, the Weſt-Indian Indigo is as beautiful as the Eaſt-Indian, when they are both wrought alike.

I think I ſhould add, that the American Indigo is better for uſe than the other; for who does not ſee, that there is no pounding this dye, without the moſt ſubtle parts being diſſipated in the air, as Mr. Tavernier allows? And who can doubt that theſe parts are the beſt, and thoſe that go fartheſt when it is uſed?

I grant that the Indigo which comes from the Eaſt-Indies, is dearer than that which is made in the Weſt-Indies; the reaſon is plain, it comes farther, runs greater riſks; and thoſe who bring it would not find their account in ſelling it, at the ſame price with that which comes from a much nearer place; but that does not at all prove it to be more beautiful, or better.

Indigo is compoſed of the ſalt and ſubſtance of the leaves and rind of a plant of the ſame name; ſo that one may ſay, it is a diſſolution or digeſtion of the plant, cauſed by the fermentation it has excited in the water it was laid to ſteep in. I know ſome writers pretend, that the ſubſtance of the leaves does not produce the Indigo, which (as they would have it) is only a viſcous tincture, or colour, which the fermentation of the plant diffuſes in the water: but before I take their words for it, I deſire they would tell me what becomes of the ſubſtance of the plant; for when it is taken out of the ſteeper, it is certain, that it has no longer the ſame weight, conſiſtence, nor colour, it had before. The leaves, which were very plump, and very full of juice, are light, flabby, and withered, and look more like dung than any thing elſe, which makes them frequently give the name of rot to the ſteeper. If then we no longer find in the leaves, and the reſt of the plant, the ſame ſubſtance that was obſervable in it before it was laid to ſteep, is it not moſt natural to believe, that it is the ſame ſubſtance and ſalts, which, being freed from their incloſures, and diffuſed in the water, have thickened it, and by their union or coagulation have formed that blue maſs which they call Indigo, ſo uſeful in painting and dyeing?

The culture.] This plant requires a good rich level ſoil, not too dry; it greatly robs and impoveriſhes the ground where it grows, and muſt be alone. There cannot be too much care taken to keep it clean, and to hinder herbs of any kind whatever from growing near it. They weed and cleanſe the ground where they intend to plant the Indigo ſeed, five times over. I ſhould think they ſhould call it ſowing, but the term of planting is conſecrated in our iſles, and I do not think I ought for the ſake of a word to fall out with our planters, who deſerve our eſteem upon a thouſand accounts, though they have got a habit of murdering the French language. They ſometimes carry their neatneſs to ſuch a pitch, that they ſweep the piece of ground as they do a room. After that they make the holes wherein the ſeeds are to be put for this purpoſe; the ſlaves, or others, who are to work at it, range themſelves in the ſame line, at the top of the piece of ground; and going backwards they make little drills the breadth of their hoe, of the depth of two or three inches, at about a foot diſtance every way, and as much as poſſible in a ſtrait line. When they are come to the end of the ground, each furniſhes himſelf with a little bag of ſeeds, and returning that way they came, they put eleven or thirteen ſeeds into each of the holes they have made. A relick of ſuperſtition has taught them that the number muſt be odd. I by no means approve of this practice, but I ſhall take care not to endeavour to ſhew them the uſeleſſneſs and folly of it, being ſatisfied I ſhall only loſe my time and labour.

This work is the moſt toilſome of any in the manufacture of Indigo; for thoſe who plant it muſt be always ſtooping, without riſing up, till the planting of the whole length of the piece is ended; ſo that when that is large, which almoſt always happens, they are obliged to remain two hours, and often more, in this poſture.

When they come to the top of the piece, they go back again, and cover the holes where they have put the ſeed in, by thruſting in with their feet the earth they had taken out of them, and ſo the ſeed is covered with about two inches of earth.

The culture of this plant may be rendered very eaſy, provided the inhabitants of our colonies in America could be brought to make uſe of the drill plough; for with this inſtrument two perſons and a horſe or mule will ſow more land with Indigo in one day, than twenty perſons can perform in the ſame time, in the method now practiſed; for the plough makes the drill, and the hopper which is fixed to the plough follows, and ſcatters the ſeeds at equal diſtances in the drills; and another inſtrument behind the hopper covers in the drills, whereby the whole operation is performed at the ſame time, and with great eaſe. Indeed the uſe of this machine muſt be underſtood by the perſons who are to perform it, otherwiſe they will do it in a bad manner, but a little practice will bring any perſon to the right uſe of it.

As the Indigo is ſown in rows, a hoeing plough may be made of a proper dimenſion, in order to clean the ground between the rows; with this contrivance it may be performed in much leſs time than in the method now practiſed. But in doing of this, I would adviſe the ſtirring of the ground, ſoon after the Indigo plants are come up, before the weeds have got much ſtrength, at which time they are ſoon deſtroyed; and by ſtirring of the ground the plants will be greatly encouraged; and the ſtrongeſt and moſt thriving plants will always make the beſt Indigo.

What Le Bat ſays of cutting the plants before they are too old, in order to have the Indigo of a better colour, is certainly right. Therefore as ſoon as the flowers begin to appear, it ſhould be cut; for if it ſtands much longer the ſtems of the plants will grow hard and ſtringy, and the lower leaves will change to a yellowiſh colour, which will render the Indigo leſs valuable; as will alſo the plants being too cloſe together, which will occaſion their bottom leaves to decay for want of free air: the ſame will happen if weeds are ſuffered to grow among the plants. Therefore there muſt be great regard to their being kept always clean.

Though all ſeaſons are good for the planting of Indigo, yet care muſt be taken not to put it in the ground in a dry time: it is true, the ſeed may keep a whole month in the ground, without being ſpoiled; but when it is planted ſo, one runs the riſk of having it eaten up by vermin, or carried away by the wind, or choked by the weeds that ſpring up with it; ſo that the prudent planters never run the riſk of planting it dry, i. e. at a time when they do not probably expect rain in two or three days after the planting is ended: they chuſe therefore, uſually, a moiſt ſeaſon, which promiſes rain, and then they are ſure of ſeeing the plant ſpring up in three or four days after its being planted.

Notwithſtanding all the care that has been taken in clearing the ground where the ſeeds have been planted, the planter muſt not be careleſs when the Indigo is got above ground; becauſe the goodneſs of the ſoil, joined to the moiſture and warmth of the climate, and the plentiful dews that fall every night, makes a prodigious quantity of weeds ſpring up, which would choke and abſolutely ſpoil the Indigo, if extreme care was not taken to weed them up as ſoon as they appear, and to keep the plant extraordinary neat; and very often the weeds are partly the cauſe of the breeding of a kind of caterpillars, which devour all the leaves in a ſhort time.

From the time of the plants riſing above ground, to its perfect maturity, is but two months, and then it is fit to cut: if one was to ſtay longer it would bloſſom, its leaves would grow drier and harder, and conſequently they would yield leſs ſubſtance, and the colour would not be near ſo beautiful.

After this firſt cutting, the new branches and leaves which the plant produces may be cut about every ſix weeks, provided the ſeaſon be rainy, and that care be taken not to cut it in a time of drought, becauſe then we ſhould infallibly loſe the plant, or, as they call it there, the Choupues, and be obliged to plant again; but all things being rightly managed, the plant may laſt two years; after which it muſt be plucked up, and new ones planted.

When the plant is ripe, which is known by the leaves, which grow brittle and leſs ſupple, they cut it ſome inches from the ground. They uſe for the cutting of it great crooked knives made like ſickles. Some planters make it into bundles like double bottles of hay, that a negro may eaſily carry them to the ſteeper; but moſt people put it into large pieces of coarſe cloth, which they tie by the four corners; and this is more convenient, the plant is leſs handled and ſqueezed, and the ſmall are carried away as ſafely as the great; and beſides the work goes on quicker this way, than in making bottles; and as time is precious every where, and eſpecially in America, there cannot be too much care taken not to loſe any.

Eighteen or twenty packets of plants, each about the ſize of two bottles of hay, are ſufficient to fill a ſteeper of the afore-mentioned ſize. When it is filled with water, ſo that it covers the plants, they put pieces of wood on the top, that the plants may not riſe above the water (much after the manner as they do upon the Grapes that are put into the preſs) and let all ferment. According as the heat is greater or leſs, or the plant more or leſs ripe, the fermentation is raiſed ſooner or later, ſometimes in ſix, eight, or ten hours; and ſometimes one is obliged to wait eighteen or twenty hours, but very ſeldom longer. Then the effect of the fermentation viſibly appears, the water heats, and boils up on all ſides, as the Grapes do in the vat; and the water which at firſt was clear, inſenſibly grows thick, and becomes of a blue, inclining to a Violet colour. Then without meddling at all with the plants, they open the cocks, which are at the bottom of the ſteeper, and let all this water, loaded with the ſalts and ſubſtance of the plant, which were freed by the fermentation, run into the battery; and while they throw away as uſeleſs, and almoſt rotten, the plants that were in the ſteeper, and clean it, that it may be filled with freſh, they beat the water, which they have let out of the ſteeper into the battery.

They formerly uſed for this purpoſe a battledoor wheel, whoſe axle was placed upon the middle of the vat, and which they turned by two handles that were at the end of the ſame axle. Since that, in the room of battledoors, they have put little bottomleſs boxes, and afterwards others, whoſe bottoms were bored full of holes: at preſent they uſe a kind of pretty large pails, faſtened to ſtrong poles, placed upon chandeliers, by means of which, the negroes violently and continually raiſe, beat, and ſtir the water, till the ſalts and other parts of the ſubſtance of the plant are united, and ſufficiently, as it were, coagulated to incorporate.

The hitting this minute exactly ſhews the ſkill of him who overſees the making of the Indigo; for if he makes them leave off beating a little too ſoon, the grain not yet formed, remains diſperſed in the water, without ſinking and gathering together at the bottom of the vat, and is loſt with the water, when they are obliged to let it out, which is a great loſs to the owner; or if when it is formed they continue to beat, they diſſolve it, and the ſame inconvenience follows. This minute then muſt be nicked, and when it is found, they muſt leave off beating and let the matter reſt.

To find this minute, they make uſe of a little ſilver cup, deſigned for this uſe alone; they fill it with this water, while the negroes beat it, and according as they obſerve that the fæces ſink to the bottom of the cup, or remain diſperſed in the water, they ceaſe, or continue beating.

The General Dictionary printed at Trevoux, relates very ſeriouſly, upon the credit of father Plumier a minim, that the Indigo-maker having taking up ſome of the water of this battery in his cup, ſpits in it; and that if the Indigo be formed, the fæces immediately ſink to the bottom of the cup, and that then he makes them leave off beating, if not, he makes them continue it. This is not the only incident in which people have impoſed upon father Plumier's credulity and ſimplicity. I have been a witneſs of it upon other occaſions.

When they have left off beating they let the matter reſt, the fæces ſink to the bottom of the vat, and gather together like a kind of mud; and the water freed from all the ſalts it was impregnated with, ſwims above it, and grows clear. Then they open the cocks, which are placed in the battery at different diſtances from the bottom, and let this water run away; and when they come to the ſurface of the fæces, they open the cocks of the bottom, that the fæces may all fall into the devilling or ſettler. There they let it ſettle a little while longer, after which they put it into linen bags, fifteen or eighteen inches long, made with a point, where it perfectly purges itſelf from the reſt of the water, which remained among its particles. When that is done, they ſpread it in little boxes three or four feet long, two feet broad, and about three inches deep, and expoſe it to the air to dry it perfectly. They obſerve not to expoſe it to the ſun, becauſe it would ſtarve the colour in drying it; and they take a great deal of care to keep it from the rain, becauſe that would diſſolve and utterly ſpoil it.

It ſometimes happens that the caterpillars get among the Indigo; and if they are let alone ever ſo little a while they eat all the leaves, and often the very rind and ends of the branches, and kill the ſtocks; it is but loſt time to endeavour to deſtroy them, or hinder them from ravaging a whole piece, by ſtopping them with a ditch. The ſureſt way is to cut down the Indigo with all ſpeed, let its age be what it will, and to throw both plants and caterpillars together into the ſteeper; there they burſt, and part with what they had devoured, and the Indigo is not the leſs beautiful for it. It is true, when the plant is not come to its perfect maturity, it yields much leſs; but many experiments have taught us, that the colour it yields is much more beautiful; ſo that what is loſt one way is gained another.

I would not wait for ſo perfect a ripeneſs before I cut the plant. Perhaps all the ſecret of thoſe, whoſe Indigo is ſo much extolled beyond ours, lies only in cutting the plant when it yields the livelieſt colour. I have experienced that in leaving ſome cochineal flies upon ſome Indian Figs, which were too ripe, inſtead of being red, they grew of a filemot colour, like the fruit they fed upon. The ſame thing might happen in Indigo; and what I here propoſe is not a groundleſs doubt, ſince it is backed by the experiment I have juſt related; which plainly proves, that the ſame plant, cut at different ages, produces colours different in beauty. I would not venture to give this advice to men wedded to their intereſt, who value the quantity rather than the quality of their commodity; but I believe I have nothing to fear from our iſlanders, who are generous and magnificent, ſometimes even beyond their abilities: I adviſe them therefore to make different trials, as to the ſoil, the ſeaſon, the age of the plant, the water they ſteep it in, the point of diſſolution, &c. and I am ſure, that with a little time, labour, and patience, they will make Indigo that will equal, and even excel, the moſt boaſted Indigo of foreign countries. The planters of St. Domingo know that in 1701 their coarſe ſugar was very bad, and was not made without infinite trouble; and at preſent every body allows, that by their labour, aſſiduity, and enquiries, it is grown much more eſteemed than that of the Windward Iſlands: why may not the ſame be hoped for in Indigo?

Mr. Pomet, author of the General Hiſtory of Drugs, ſays in his firſt part, chap. 10. That the Indians of the village of Sarqueſſe, near Amadabat, uſe only the leaves of the Indigo, and throw away the plant and branches; and that it is from thence the moſt eſteemed Indigo comes.

I am pretty much of his opinion; for we ſee, that thoſe who take the pains to ſtrip off the Grapes from the branches, before they put them into the vat, and throw away the ſtalks entirely, make much the beſt wine; becauſe the ſtalks always contain an acid, which mixes with the juice of the Grape in the treading and preſſing them both together; and for the ſame reaſon, the ſtalks of the Indigo plant muſt contain a liquid much leſs perfect in colour than that of the leaves: but one ought to have the leiſure and patience of the Indians to undertake ſuch a work, and have workmen as cheap as they are in that country, ſuppoſing the fact true, as Mr. Pomet delivers it from the relation of Mr. Tavernier.

Though I am a great friend to thoſe experiments which may carry our manufactures to a greater perfection, yet I dare not propoſe this, becauſe of the expence they muſt be at, who would try it; and becauſe the profit ariſing from it would not perhaps quit coſt: however, I have here given the method of the Indians of Sarqueſſe, that I may have no reaſon to reproach myſelf with having omitted a thing which may be of ſome uſe to my country.

Good Indigo ought to be ſo light, as to ſwim upon water; the more it ſinks the more it is to be ſuſpected of being mixed with earth, aſhes, or powdered ſlate. Its colour ought to be a deep blue, inclining to a Violet, brilliant, lively, and bright: it ought to be more beautiful within than without, and look ſhining, and as it were ſilvered.

If it is too heavy in proportion to its bulk, it ought to be ſuſpected, and its quality examined into; for as it often bears a conſiderable price, it is fit that thoſe who buy it, ſhould be acquainted with the frauds that may be committed in it.

The firſt is the beating the plant too much in the ſteeper, that the leaves and rind of it may be entirely conſumed. It is certain that the quantity of the matter is very conſiderably increaſed by this diſſolution, but the Indigo is a great deal the leſs beautiful for it; it is blackiſh, thick, heavy, and fitter to be thrown away than uſed.

The ſecond is the mixing aſhes, earth, or a certain brown ſhining ſand (which is pretty commonly found in the bays by the ſea-ſide) and eſpecially powdered ſlate, with the fæces, as they fall into the devilling, and ſtirring all well together, that it may incorporate, and the fraud not appear: and this fraud is much more eaſily committed in the powdered Indigo, than in that which is in cakes; becauſe it is very difficult for thoſe heterogeneous bodies to unite ſo well together, as not to make in many places, as it were, beds of a different matter; and then, by breaking the piece of Indigo, they are eaſily perceived.

The two following expedients may be made uſe of, in order to know the goodneſs or badneſs of Indigo.

The firſt is to diſſolve a bit of it in a glaſs of water. If it is pure and well made, it it will entirely diſſolve; but if it is adulterated, the foreign matter will ſink to the bottom of the glaſs.

The ſecond is to burn it. The good Indigo will burn all away, whereas the aſhes, earth, ſand, and ſlate, remain after the true Indigo is conſumed.

In 1694, Indigo was ſold at the Windward Iſlands, from three livres ten ſols, to four livres per pound, according to its beauty, and the number of veſſels to be freighted with it. I have known it ſince at a much lower price; however, the planter would not fail of making a very conſiderable profit of it, though he ſhould ſell it for no more than forty ſols per pound, becauſe this commodity requires fewer utenſils and leſs charges than a ſugar-work.

Since the cultivation of Indigo was introduced in South Carolina, great quantities of that uſeful dye has been brought from thence to England; and it may be hoped that the encouragement granted by parliament to the planters, will enable them to proſecute this branch of commerce with ſuch ſucceſs, as to be a great national benefit, and of equal advantage to that colony: but as yet the planters have not arrived to ſo much perfection in the making of it as could be wiſhed; for moſt of the Indigo which I have ſeen of the produce of that country, has been ſo hard as to render it difficult to diſſolve, occaſioned by their pouring a quantity of lime-water into the vat, in order to make the fæces of the plant ſubſide. I have alſo been informed by letters from many of the planters, that after the fermentation of the plant in the vat, it comes out again almoſt entire, being but in a very ſmall proportion leſſened, either in bulk or weight. This may probably be owing, in great part, to their culture of the plant, as alſo from their vats not being large enough to contain a ſufficient quantity of the herb, to make the fermentation ſtrong enough to diſſolve it; or from the vats being built in the open air, whereby the fermentation may be impeded, by the cooler breezes of the evening air: for in the iſlands where the beſt Indigo is made, their vats are all built under cover, where their heat is much greater than that in Carolina, therefore this requires the attention of the planters of Indigo.

As to the culture of the plant, by all the information I have been able to procure from thence, they commit a great error in ſowing their ſeeds too thick, whereby the plants are drawn up with ſlender ſtems, which are not ſufficiently garniſhed with leaves; nor are the leaves ſo large and ſucculent as they would naturally grow, were the plants allowed a greater ſhare of room, ſo that the ſtalks conſiſt of little elſe but ſtrong veſſels, which are not diſſolvable by the fermentation, and it is only the upper parts of the plant which are furniſhed with leaves, like young trees growing cloſe together which are drawn up with ſlender ſtems, having no lateral branches, nor leaves, but at their tops; therefore it is not to be ſuppoſed, a great quantity of Indigo can be produced from plants ſo managed; for it is a common obſervation of the cultivators of Woad, that when their plants ſpire, and have narrow thin leaves, they produce but little of the dye; ſo that they make choice of rich ſtrong land for ſowing the ſeeds of this plant, and are careful to thin them, that they may have room to ſpread, and produce large ſucculent leaves, from which they always reap the greateſt profit. If the planters of Indigo in America would but imitate the cultivators of Woad in this particular, they would certainly find their advantage in ſo doing.

Another thing in which they err is, letting the plant ſtand too long before they cut it, ſuppoſing from the height of the plant to procure a great quantity of the dye; but in this they are greatly miſtaken, for the older the plant is before it is cut, the drier and firmer will be the ſtalks; therefore but little of the plant will be diſſolved by fermentation, nor will the fæces of the old plants be near ſo beautiful as that of the young. Therefore it is to be wiſhed, that they would try ſome few experiments in the culture and management of the plants, by ſowing thin, and keeping the plants perfectly clean from weeds; as alſo to cut them while young and full of juice, and hereby they will be better informed how to improve it to the greateſt advantage. But as labour is dear in that country, ſo many perſons probably object to the expence of cultivating the Indigo in this method; therefore, to avoid this, I have before propoſed ſowing the ſeeds with a drill plough, whereby the firſt expence will be greatly leſſened, and the ſeeds more equally ſown; and by the uſe of the hoe plough, ten acres may be kept clean from weeds with as ſmall expence, as one when managed by the hand hoe; and by ſtirring of the ground often, and earthing up the plants, they would grow much ſtronger, be leſs liable of being deſtroyed by flies, and have larger and more ſucculent ſtalks and leaves.

INGA. See Mimosa.

INOCULATING, or Budding. This is commonly practiſed upon all ſorts of ſtone fruit, in particular, ſuch as Peaches, Nectarines, Cherries, Plums, &c. as alſo Oranges and Jaſmines, and is preferable to any ſort of grafting for moſt ſorts of fruit. The method of performing it is as follows: you muſt be provided with a ſharp penknife, having a flat haft (the uſe of which is to raiſe the bark of the ſtock, to admit the bud) and ſome ſound baſs mat, which ſhould be ſoaked in water to increaſe its ſtrength, and make it more pliable; then having taken off the cuttings from the trees you would propagate, you ſhould chooſe a ſmooth part of the ſtock about five or ſix inches above the ſurface of the ground, if deſigned for dwarfs, and for half ſtandards at three feet; but for ſtandards, they ſhould be budded ſix or more feet above ground; then with your knife make an horizontal cut croſs the rind of the ſtock, and from the middle of that cut make a ſlit downwards about two inches in length, ſo that it may be in the form of a T; but you muſt be careful not to cut too deep, leſt you wound the ſtock: then having cut off the leaf from the bud, leaving the foot-ſtalk remaining, you ſhould make a croſs cut about half an inch below the eye, and with your knife ſlit off the bud, with part of the wood to it, in form of an eſcutcheon: this done, you muſt with your knife pull off that part of the wood which was taken with the bud, obſerving whether the eye of the bud be left to it, or not (for all thoſe buds which loſe their eyes in ſtripping, ſhould be thrown away, being good for nothing) then having gently raiſed the bark of the ſtock where the croſs inciſion was made, with the flat haft of your penknife clear to the wood, you ſhould thruſt the bud therein, obſerving to place it ſmooth between the rind and the wood of the ſtock, cutting off any part of the rind belonging to the bud, which may be too long for the ſlit made in the ſtock; and ſo having exactly fitted the bud to the ſtock, you muſt tie them cloſely round with baſs mat, beginning at the under part of the ſlit, and ſo proceed to the top, taking care that you do not bind round the eye of the bud, which ſhould be left open.

When your buds have been inoculated three weeks or a month, you will ſee which of them have taken; thoſe of them which appear ſhrivelled and black, being dead, but thoſe which remain freſh and plump, you may depend are joined; and at this time you ſhould looſen the bandage, which, if not done in time, will pinch the ſtock, and greatly injure, if not deſtroy, the bud.

The March following you muſt cut off the ſtock about three inches above the bud, ſloping it that the wet may paſs off, and not enter the ſtock; to this part of the ſtock left above the bud, it is very proper to faſten the ſhoot which proceeds from the bud, and would be in danger of being blown out, if not prevented; but this muſt continue no longer than one year, after which it muſt be cut off cloſe above the bud, that the ſtock may be covered thereby.

The time for Inoculating is, from the middle of June until the middle of Auguſt, according to the forwardneſs of the ſeaſon, and the particular ſorts of trees to be propagated; but the time may be eaſily known, by trying the buds, whether they will come off well from the wood. However, the moſt general rule is, when you obſerve the buds formed at the extremity of the ſame year's ſhoots, which is a ſign of their having finiſhed their ſpring growth. The firſt ſort commonly inoculated is the Apricot, and the laſt the Orange-tree, which ſhould never be done until the middle of Auguſt; and in doing of this work, you ſhould always make choice of cloudy weather; for if it be done in the middle of the day, in very hot weather, the ſhoots will perſpire ſo faſt, as to leave the buds deſtitute of moiſture; nor ſhould you take off the cuttings from the trees long before they are uſed; but if you are obliged to fetch your cuttings from ſome diſtance, as it often happens, you ſhould then be provided with a tin box or caſe, having a ſocket about ten inches long, and a cover to the top, which muſt have five or ſix holes; in this ſocket you ſhould put as much water as will fill it about two or three inches high, and place your cuttings therein in an upright poſition, ſo that that part which was cut from the tree may be ſet in the water, and ſo faſten down the cover to keep out the air; and the holes in the cover will be ſufficient to let the perſpiration of theſe branches paſs off, which, if pent in, would be very hurtful to them; you muſt alſo be careful to carry it upright, that the water may not reach to the buds; for it is a very wrong practice in thoſe who throw their cuttings all over in water, which ſo ſaturates the buds with moiſture, that they have no attractive force left to imbibe the ſap of the ſtock, whereby they very often miſcarry.

But before I leave this head, I beg leave to obſerve, that though it is the ordinary practice to diveſt the bud of that part of the wood which was taken from the ſhoot with it; yet, in many ſorts of tender trees, it is beſt to preſerve a little wood to the bud, without which they often miſcarry. The not obſerving this, has occaſioned ſome people to imagine, that ſome ſorts of trees are not to be propagated by Inoculation; whereas, if they had performed it in this method, they might have ſucceeded, as I have ſeveral times experienced.

INTYBUS. See Cichorium.

INULA. Lin. Gen. Plant. 860. Enula. Cæſalp. Helenium. Raii Meth. 33. Aſter. Tourn. Inſt. R. H. 481. tab. 274. Elecampane.

The Characters are,

It hath a radiated compound flower, with an imbricated empalement, compoſed of looſe, ſpreading, ſmall leaves, the outer being the broadeſt. The diſk, or middle of the flower, is compoſed of hermaphrodite florets, and the border, or ray of the female half florets, ſtretched out like a tongue. The hermaphrodite florets are funnel-ſhaped, erect, and cut into five ſegments at the top; theſe have five ſhort ſlender ſtamina, terminated by cylindrical ſummits, which coaleſce at the top: they have one long germen, crowned with down, ſupporting a ſlender ſtyle the length of the ſtamina, crowned by an upright bifid ſtigma. The female half florets have a narrow entire tongue, no ſtamina, but a long crowned germen with a hairy ſtyle, and an upright ſtigma. The germen in both flowers become a ſingle, narrow, four-cornered ſeed, crowned with a down, ſitting on a naked receptacle.

This genus of plants is ranged in the ſecond ſection of Linnæus's nineteenth claſs, intitled Syngeneſia Polygamia ſuperflua, which includes the plants with a compound flower, made up of hermaphrodite florets in the diſk, and female half florets for the rays, which are fruitful.

The Species are,

1. Inula (*Helenium*) foliis amplexicaulibus ovatis, rugoſis, ſubtus tomentoſus, calycum ſquamis ovatis. Amœn. Acad. 1. p. 410. *Elecampane with oval rough leaves, which embrace the ſtalks, woolly on their under ſide, and the ſcales of the empalement oval.* Aſter omnium maximus, Helenium dictus. Tourn. Inſt. 483. *The greateſt Starwort, called Elecampane.*
2. Inula (*Odora*) foliis amplexicaulibus dentatis hirſutiſſimis radicalibus ovatis, caulinus lanceolatis caule paucifloro. Lin. Sp. Plant. 1236. *Inula with hairy indented leaves embracing the ſtalks, thoſe at the bottom oval, but thoſe on the ſtalks ſpear-ſhaped, which have but few flowers.* Aſter luteus radice odorâ. C. B. P. 266. *Yellow Starwort with a ſweet root.*
3. Inula (*Salicina*) foliis ſeſſilibus lanceolatis recurvis ſerrato-ſcabris, floribus inferioribus altioribus, ramis ſub-angulatis. Amœn. Acad. 1. p. 410. *Inula with ſpear-ſhaped, recurved, rough, ſawed leaves, ſitting cloſe to the ſtalks, and the under flowers growing taller than the upper, and angular branches.* Aſter montanus luteus, ſalicis glabro folio. C. B. P. 266. *Yellow Mountain Starwort with a ſmooth Willow leaf.*
4. Inula (*Germanica*) foliis ſeſſilibus lanceolatis recurvis, ſcabris, floribus ſubfaſciculatis. Lin. Sp. Plant. 883. *Inula with ſpear-ſhaped recurved leaves ſitting cloſe to the ſtalks, which are rough, and flowers growing in cluſters.* Aſter Thuringiacus altiſſimus latifolius, montanus, flore luteo parvo. Haller. Jen. 181. *Talleſt broad-leaved Mountain Starwort of Thuringia, with a ſmall yellow flower.*
5. Inula (*Crithmoides*) foliis linearibus carnoſis tricuſpidatis. Lin. Sp. Plant. 883. *Inula with narrow fleſhy leaves ending in three points.* Aſter maritimus flavus crithmum chryſanthemum dictus. Raii Syn. Ed. 3. p. 174. *Yellow maritime Starwort, called Golden Samphire.*
6. Inula (*Montana*) foliis lanceolatis hirſutis integerrimis, caule unifloro calyce brevi imbricato. Lin. Sp. Plant. 124. *Inula with hairy, ſpear-ſhaped, entire leaves, one flower on a ſtalk, having a ſhort ſcaly cup.* Aſter montanus luteo magno flore. C. B. P. 267. *Mountain Starwort with a large yellow flower.*
7. Inula (*Oculis Chriſti*) foliis amplexicaulibus oblongis, integerrimis hirſutis, caule piloſo, corymboſo. Lin. Sp. Plant. 1237. *Inula with oblong, entire, hairy leaves, and flowers growing in a corymbus.* Conyza Pannonica lanuginoſa. C. B. P. 265. *Hungarian woolly Fleabane.*
8. Inula (*Britannica*) foliis amplexicaulibus lanceolatis, diſtinctis ſerratis, ſubtus villoſis, caule ramoſo villoſo erecto. Flor. Suec. 756. *Inula with ſpear-ſhaped ſawed leaves embracing the ſtalk, hairy on their under ſide, and an erect branching ſtalk.* Aſter paluſtris luteus, folio longiore lanuginoſo. Tourn. Inſt. 483. *Yellow Marſh Starwort with a longer woolly leaf.*

9. Inula (*Hirta*) foliis ſeſſilibus lanceolatis, recurvatis, ſubſerrato-ſcabris, floribus inferioribus, altioribus, caule teretiuſculo ſubpiloſo. Lin. Sp. 1239. *Inula with ſpear-ſhaped, recurved, rough leaves, ſitting cloſe to the ſtalks, and the lower flowers riſing above the other.* Aſter luteus, ſalicis folio hirſuto. C. B. P. 266. *Yellow Aſter with a hairy Willow leaf.*

10. Inula (*Bifrons*) foliis oblongis decurrentibus denticulatis, floribus congeſtis terminalibus ſubſeſſilibus. Lin. Sp. 1236. *Inula with oblong indented leaves running along the ſtalks, and flowers in cluſters terminating the ſtalks.* Conyza Pyrenaica, foliis primulæ veris. Par. Bat. 127.

11. Inula (*Squaroſa*) foliis ovalibus lævibus reticulato-venoſis ſubcrenatis, calycibus ſquarroſis. Lin. Sp. 1240. *Inula with ſmooth oval leaves and netted veins, with rough empalements to the flowers.* Aſter Conyzoides odoratus luteus. Tourn. Inſt. 483.

12. Inula (*Canarienſis*) foliis linearibus carnoſis tricuſpidatis, caule fruticoſo. *Inula with narrow, fleſhy, three-pointed leaves, and a ſhrubby ſtalk.* Aſter Canarienſis fruteſcens, folio tridentato craſſo. Hort. Chelſ. 26. *Shrubby Canary Starwort with a thick leaf, ending in three points.*

13. Inula (*Saturejaoides*) foliis linearibus hirſutis oppoſitis, pedunculatis nudis unifloris. *Inula with narrow hairy ſtalks placed oppoſite, and naked foot-ſtalks, having one flower.* Aſter ſaturejæ foliis conjugatis & piloſis, flore luteo. Houſt. MSS. *Starwort with hairy Savoury leaves growing by pairs, and a yellow flower.*

14. Inula (*Mariana*) caule erecto hiſpido, foliis lanceolatis aſperis, floribus alaribus ſolitariis ſeſſilibus, terminalibus umbellatis. *Inula with an erect prickly ſtalk, ſpear-ſhaped rough leaves, flowers proceeding ſingly from the ſides of the ſtalks, ſitting cloſe, and terminating in an umbel.* Aſter luteus Marianus Saligneis brevioribus foliis hirſutis pubeſcentibus, ſummo caule ramoſus. Pluk. Mant. 30. *Yellow Starwort of Maryland, with ſhorter, ſallow, hairy leaves, and the top of the ſtalk branching.*

15. Inula (*Fruticoſa*) foliis lanceolatis acutis, ſubtus trinerviis, ſquamis calycinis acutis caule fruticoſa. *Inula with ſpear-ſhaped acute leaves, having three veins on their under ſide, the ſcales of the empalement ſharp-pointed, and a ſhrubby ſtalk.*

The firſt ſort grows naturally in ſeveral parts of England, but it is alſo cultivated in gardens for the ſake of the roots, which are uſed in medicine, and are accounted carminative, ſudorific, and alexipharmic, of great ſervice in ſhortneſs of breath, coughs, ſtuffing of the lungs, and infectious diſtempers.

This hath a perennial root, which is thick, branching, and of a ſtrong odour. The lower leaves are a foot long, and four inches broad in the middle, rough on their upper ſide, but downy on their under. The ſtalks riſe about three feet high, and divide toward the top into ſeveral ſmaller branches, garniſhed with oblong oval leaves, which are indented on their edges, and end in acute points. The flowers terminate the ſtalks, each branch ending with one large, yellow, radiated flower, ſitting in a ſcaly empalement, whoſe ſcales are oval, and placed like the ſcales on fiſh over each other. The flowers are ſucceeded by narrow four-cornered ſeeds crowned with down. It flowers in June and July, and the ſeeds ripen the latter end of Auguſt.

This ſort may be propagated by ſeeds, which ſhould be ſown in autumn ſoon after they are ripe; for if they are kept till the ſpring, they ſeldom grow; but where they are permitted to ſcatter, the plants will come up the following ſpring without any care, and may be either tranſplanted the following autumn; or if they are deſigned to remain, they ſhould be hoed out to the diſtance of ten inches, or a foot each way, and conſtantly kept clean from weeds; theſe roots will be fit for uſe the ſecond year.

But moſt people propagate the plant by offſets, which, if carefully taken from the old roots, with a bud, or eye, to each, will take root very eaſily; the beſt time for this is the autumn, as ſoon as the leaves begin to decay; theſe ſhould be planted in rows about a foot aſunder, and nine or ten inches diſtance in the rows; the ſpring following the ground muſt be kept clean from weeds, and if in autumn it is ſlightly dug, it will promote the growth of the roots; theſe will be fit for uſe after two years growth, but the roots will abide many years, if they are permitted to ſtand; however, the young roots are preferable to thoſe which are old and ſtringy. It loves a gentle loamy ſoil, not too dry.

The ſecond ſort hath a perennial root, from which ariſe ſeveral ſtalks, about two feet high. The leaves at bottom are oval, indented, and hairy; thoſe above embrace the ſtalks with their baſe. The ſtalks are divided into ſeveral branches, garniſhed with a few ſcattering yellow flowers. The root has a very ſweet odour when broken. It flowers in July, but rarely ripens ſeeds here.

The third ſort hath a perennial root, from which ariſes many ſpear-ſhaped leaves, which are ſmooth and recurved. The ſtalks riſe near two feet high; they are angular, and branch at the top into ſeveral foot-ſtalks, each ſuſtaining one yellow radiated flower. It flowers in June, July, and Auguſt, and the ſeeds ripen in September.

The fourth ſort riſes with an upright ſtalk between three and four feet high, with ſpear-ſhaped leaves, which are turned backward, indented on their edges, and rough on their upper ſide. The flowers are collected in cloſe bunches on the upper part of the ſtalks; they are ſmall and yellow. It grows on the Alps, and other mountainous parts of Europe. It flowers in June, and the ſeeds ripen in autumn.

The fifth ſort grows naturally on the ſea-coaſts in many parts of England. I have ſeen it growing plentifully near Sheerneſs, in the iſle of Sheepy, in Kent; this riſes with an upright ſtalk a foot and a half high, garniſhed with fleſhy ſucculent leaves, which come out in cluſters, and are about an inch and a quarter long, and one eighth of an inch broad, ending in three points. The flowers come out at the top of the ſtalks in ſmall umbels; they are yellow, and have a border of rays; this flowers in July, and the ſeeds ripen in autumn. The younger branches of this plant are frequently ſold in the London markets for Samphire; but this is a great abuſe, becauſe this plant has none of the warm aromatic taſte of the true Samphire.

The ſixth ſort grows naturally in Germany; this riſes with upright ſtalks a foot and a half high, garniſhed with ſpear-ſhaped leaves which are covered with ſoft hairs, and are entire. The ſtalks each ſupport one large yellow flower, which appears in July, but rarely ripens ſeeds here.

The ſeventh ſort hath a perennial root and an annual ſtalk; this grows naturally in Hungary. The leaves are oblong and hairy; the ſtalks branch at the top in form of a corymbus. The flowers are ſmall, yellow, and are in cloſe cluſters; theſe appear in July, but ſeldom perfect ſeeds in England.

The eighth ſort grows naturally in Auſtria, Bohemia, and other parts of Germany; it hath a perennial root, and an annual ſtalk which riſes near two feet high, garniſhed with ſpear-ſhaped woolly leaves, which are ſawed, and cloſely embrace the ſtalks with their baſe. The upper part of the ſtalk divides into two or three erect branches, or foot-ſtalks, each ſuſtaining one pretty large deep yellow flower; theſe are in beauty in July, but ſeldom ripen ſeeds here.

The ninth ſort grows naturally in the ſouth of France, Spain, and Italy; this hath a perennial root, from whence ariſe ſeveral ſtalks about one foot high; the lower leaves are ſpear-ſhaped and prickly; the upper half embrace the ſtalks, which divide into ſeveral branches, each being terminated by one yellow flower, which appears in July, but ſeldom perfects ſeeds here.

The tenth ſort riſes about a foot high, dividing into many branches, which are garniſhed by oval hairy leaves, which half embrace the ſtalks with their baſe;

each of the branches is terminated by one large yellow flower, whoſe empalement is compoſed of oval ſcales. It flowers in July and Auguſt, but never perfects ſeeds in this country.

The eleventh ſort grows naturally in Hungary; this riſes with ſingle upright ſtalks near two feet high, garniſhed with oval ſpear-ſhaped leaves, which are ſlightly indented on the edges, and ſit cloſe to the ſtalks, which are hairy, and divide in form of a corymbus at the top. The flowers are pretty large, of a pale yellow colour, and appear in July, but are not ſucceeded by ſeeds in this country.

The twelfth ſort grows naturally in the Canary Iſlands; this riſes with ſeveral ſhrubby ſtalks near four feet high, which divide into ſmaller branches, garniſhed with cluſters of narrow fleſhy leaves, which are divided into three ſegments at their points. The flowers come out on the ſide of the branches at the top of the ſtalks; they are ſmall, and of a pale yellow colour, appearing in Auguſt.

The ſecond, third, fourth, ſixth, ſeventh, eighth, and ninth ſorts are abiding plants, which will thrive and flower in the open air in England; they may be all propagated by parting of their roots. The beſt time for doing of this is in autumn, at which time the plants may be removed; theſe may be intermixed with other flowering plants in the borders of large gardens, where they will make an agreeable variety during their continuance in flower. As theſe roots multiply pretty faſt, they ſhould be allowed room to ſpread, therefore ſhould not be planted nearer than two feet from other plants; and if they are removed every third year, it will be often enough, provided the ground between them is dug every winter, and, in ſnmmer, if they are kept clean from weeds, they will require no other care.

As ſome of theſe ſorts produce good ſeeds in England, they may be propagated by ſowing of the ſeeds in the autumn, on a border of light earth expoſed to the eaſt, where the morning ſun only is admitted; and in the ſpring, when the plants appear, they ſhould be kept clean from weeds till they are fit to remove, when they ſhould be tranſplanted on a ſhady border, ſix inches aſunder, obſerving to ſhade and water them till they have taken new root; and during the ſummer ſeaſon they ſhould be kept clean from weeds, and in autumn they may be tranſplanted into the borders where they are to remain.

The tenth ſort grows naturally in the ſouth of France, and on the Pyrenean mountains. This hath a thick fibrous root, which is perennial, ſending out many oblong indented leaves, whoſe baſe runs along the ſtalks from one joint to another: from the root ariſe three or four ſtalks about two feet high, which divide each into three or four ſmall branches, which are terminated by cluſters of ſmall yellow flowers, ſitting cloſe between the ſmall leaves; theſe appear in June and July, and are ſucceeded by narrow ſeeds, crowned with down, which ripen in the autumn.

It is propagated by ſeeds, which ſhould be ſown on a bed of light earth early in the ſpring; in May the plants will appear, which ſhould be kept clean from weeds till they are fit to tranſplant, when they ſhould be planted in an eaſt border, at about ſix inches diſtance each way, watering and ſhading them till they have taken new root; after which they will require no other culture but to keep them clean from weeds till the autumn, when they ſhould be planted where they are deſigned to remain.

The eleventh ſort grows naturally near Montpelier, and alſo in Italy; this hath a fibrous root, from which ariſe two or three erect ſtalks about two feet high, garniſhed with ſmooth oval leaves placed alternate, ſitting cloſe to the ſtalks; the veins of the leaves are ſlender, and formed like net-work. The ſtalks are terminated by one yellow flower incloſed in a rough ſcaly empalement, and at the two joints of the ſtalk immediately under the flower, come out ſmall footſtalks, with ſmaller flowers than thoſe on the top.

This plant ſeldom continues above two or three years, therefore young plants ſhould be raiſed from ſeeds to ſucceed them. The ſeeds may be ſown at the ſame time, and in the ſame manner as is directed for the tenth ſort, and the plants afterward treated in the ſame way.

The fifth ſort grows naturally in the ſalt marſhes in ſeveral parts of England, which are flowed by the tides, therefore is ſeldom admitted into gardens. The roots of this are perennial, but the ſtalks decay in autumn; and if any one has curioſity to keep a plant or two of it in their gardens, they may tranſplant it into a ſhady border from the place of its natural growth, and, by keeping it moiſt in dry weather, it will thrive pretty well, but the ſtalks will not riſe ſo high, nor will the leaves be near ſo fleſhy as in the ſalt marſhes.

The twelfth ſort will not live abroad in the open air in England, during the winter ſeaſon, ſo muſt be removed into ſhelter in autumn, but ſhould have as much free air as poſſible at all times, when the weather is mild, otherwiſe it is apt to draw up weak. In cold weather the plants muſt have very little water, for their ſtalks and leaves being ſucculent, they are very apt to rot with too much wet; in ſummer they ſhould be placed abroad with other hardy exotic plants in a ſheltered ſituation, where they will add to the variety, though they are plants of no great beauty, and ſeldom flower in England, unleſs the ſummer is very warm. This is eaſily propagated by cuttings, any time in ſummer, which, if planted in a ſhady border, will take root in a ſhort time.

The thirteenth ſort was diſcovered by the late Dr. Houſtoun, growing naturally at La Vera Cruz; this riſes with a ſhrubby ſtalk about two feet high, dividing into many ſmaller branches, which are hairy, and garniſhed with narrow ſtiff leaves placed oppoſite, without foot-ſtalks; from the edges of theſe ariſe long hairs, which are ſtiff, and come out by pairs; at the end of the branches ariſe the naked foot-ſtalks, which are four or five inches long, ſuſtaining one ſmall, yellow, radiated flower.

This is propagated by cuttings during the ſummer ſeaſon, which muſt planted on a bed of light earth, and ſhaded till they have taken root; after which the plants muſt be treated in the ſame manner as other hardy exotics, ſheltering them from froſt in winter.

The fourteenth ſort was ſent me from Maryland, where it grows naturally; this riſes with a ſtrong ſtalk about a foot and a half high, which is pretty cloſely ſet with prickly hairs, and garniſhed with rough ſpear-ſhaped leaves, about three inches long, and near one inch broad in the middle: toward the upper part of the ſtalk there are ſingle flowers coming from the wings at each joint, and the ſtalk is terminated by a cluſter of ſmall yellow flowers, diſpoſed in form of an umbel. This plant flowers here in Auguſt, but has not as yet perfected ſeeds in England.

The fifteenth ſort was diſcovered growing naturally at Carthagena, by the late Dr. Houſtoun; this riſes with a ſhrubby ſtalk to the height of ten or twelve feet, divided into ſeveral ligneous branches, garniſhed with ſpear-ſhaped leaves five inches long, and one inch and a half broad in the middle, and ſmooth on their upper ſide, but on their under have three longitudinal veins. The flowers are produced at the end of the branches, having very large ſcaly empalements; they are as large as a ſmall Sun-flower, of a pale yellow colour. This plant is too tender to live in the open air in England, ſo muſt be conſtantly kept in the bark-ſtove. It is propagated by ſeeds, which muſt be procured from the country where it naturally grows, for it does not produce any here; theſe muſt be ſown upon a hot-bed, and when the plants are fit to remove, they ſhould be each planted into a ſmall pot filled with light earth, and plunged into a freſh hot-bed, treating them in the ſame manner as other tender plants from the ſame country.

JOHNSONIA. Dale. Callicarpa. Lin. Gen. Plant. 127. Spondylococus. Mitch. 20. This plant was ſo titled by the late Dr. Dale, of South Carolina, in memory of Dr. Johnſon, who publiſhed an edition of Gerard's Herbal, corrected and much improved.

The Characters are,

The flower hath an empalement of one leaf, cut at the brim into four ſhort ſegments, which are erect. It hath one petal, which is tubulous, and divided into four parts at the brim, which ſpread open. It hath four ſlender ſummits, which are longer than the petal, terminated by oblong yellow ſummits. In the center is ſituated a roundiſh germen, ſupporting a ſlender ſtyle, crowned by a thick obtuſe ſtigma. The germen afterward becomes a ſmooth globular berry, incloſing four hard oblong ſeeds.

Dr. Linnæus ranges this genus of plants in the firſt ſection of his fourth claſs, intitled Tetrandria Monogynia, which includes the plants whoſe flowers have four ſtamina and one ſtyle. As the ſeeds of this plant were ſent me from Carolina by the late Dr. Dale with this title, in the year 1739, and with them the characters of the genus, which was before it was mentioned by Dr. Linnæus, I have continued it under the Doctor's title.

We have but one Species of this genus, viz.

Johnsonia (*Americana*) floribus verticillatis ſeſſilibus, foliis ovato lanceolatis oppoſitis, caule fruticoſo. Dale. *Shrubby Johnſonia with oval ſpear-ſhaped leaves placed oppoſite, and flowers growing in whorls ſitting cloſe to the ſtalks.* Callicarpa. Act. Upſal. 1741. Mr. Cateſby, in his Hiſtory of Carolina, has figured it under the following title, Frutex baccifer verticillatus, foliis ſcabris latis dentatis & conjugatis, baccis purpureis denſè congeſtis, vol. ii. p. 47.

This ſhrub grows plentifully in the woods near Charles-town, in South Carolina. It riſes from four to ſix feet high, ſending out many branches from the root, which are woolly when young, like thoſe of the Wayfaring-tree, garniſhed with oval ſpear-ſhaped leaves placed oppoſite, ſtanding on ſhort foot-ſtalks; they are about three inches long, and one inch and a quarter broad in the middle, growing narrow at both ends, and a little indented on their edges, their ſurface rough, and a little hoary. The flowers come out in whorls round the ſtalks, ſitting very cloſe to the branches at the foot-ſtalks of the leaves; they are ſmall, tubulous, cut into four obtuſe ſegments at the top, which expand, and are of a deep purple colour; theſe are ſucceeded by ſoft ſucculent berries, which turn firſt to a bright red colour, but afterward change to a deep purple when ripe, and incloſe four hard oblong ſeeds.

The ſeeds of this plant were ſent me by Mr. Cateſby, from Carolina, in 1724; and many of the plants were then raiſed in ſeveral curious gardens in England; moſt, if not all of them were afterward planted in the open air, where they flouriſhed very well for ſome years, and ſeveral of the plants produced flowers in the Chelſea garden for four or five years, but theſe were not ſucceeded by fruit; and in the ſevere froſt in 1740, they were moſt of them deſtroyed, as were alſo the young plants which were raiſed from Dr. Dale's ſeeds the year before, which were only ſheltered under a frame; ſo that until the Doctor ſent a freſh ſupply of ſeeds in 1744, there were ſcarce any of the plants living in the Engliſh gardens; but ſince then, there has been quantities of the ſeeds brought to England.

This plant riſes eaſily from ſeeds, if they are ſown in a moderate hot-bed; the beſt way is to ſow the ſeeds in pots, and plunge them into a tan-bed of a moderate warmth; and when the plants come up, and have obtained ſome ſtrength, they ſhould be gradually inured to the open air, into which they ſhould be removed in June, and placed in a ſheltered ſituation, where they may remain till autumn; during which time they muſt be kept clear from weeds, and gently refreſhed with water in dry weather; but as theſe young plants are tender, they ſhould be placed under a frame before the early froſt comes on; for a froſt in autumn will kill the tender part of their ſhoots, which often cauſes their ſtalks to decay moſt part of their length before the ſpring. During the winter ſeaſon they ſhould be ſcreened from froſt, but in mild weather they muſt enjoy the free air, otherwiſe their ſhoots will turn mouldy and decay. The following ſpring, juſt before the plants ſhoot, they ſhould be carefully turned out of the pots, ſo as not to break their roots; and part of them may be planted in ſmall pots filled with light earth, and the others into a nurſery-bed in a warm ſituation, at about four or five inches aſunder; thoſe in the pots ſhould be plunged into a moderate hot-bed, which will forward their taking root; but afterward muſt be hardened to bear the open air as before; theſe plants in the pots ſhould be ſheltered under a frame in winter for three or four years, till they have obtained ſtrength; then they may be turned out of the pots, and planted in a warm ſituation, where they will live in the open air in common winters; but in ſevere froſt they are in danger of being killed, if they are not ſheltered; therefore the ſurface of the ground about their roots ſhould be covered with old tan to keep out the froſt, and their tops covered with Straw, Peas-haulm, or Fern, which will protect them.

Thoſe plants in the beds ſhould alſo be covered with mats, or Straw, in froſty weather, and after they have obtained ſtrength, they may be tranſplanted into a warm ſituation, and treated every winter in the ſame manner as the other.

The leaves of this ſhrub were often uſed by Dr. Dale, in dropſical caſes, with very good ſucceſs. A particular account of the virtues of this, and many other plants of Carolina, was ſent me with dried ſamples of each, by the Doctor, during the laſt war; but as the ſhips were taken in their paſſage, they were all loſt, and the Doctor dying ſoon after, I could never recover them.

JONTHLASPI. See Clypeola.

JONQUIL. See Narcissus.

IPOMOEA. Lin. Gen. Plant. 199. Quamoclit. Tourn. Inſt. R. H. 116. tab. 39. *Quamoclit, or Scarlet Convolvulus.*

The Characters are,

The flower hath a ſmall permanent empalement, cut into five parts at the top. The petal is funnel-ſhaped, having a long cylindrical tube, whoſe brim is five-pointed, ſpreading open flat. It hath five awl-ſhaped ſtamina, nearly the length of the petal, terminated by roundiſh ſummits. In the bottom of the tube is ſituated a round germen, ſupporting a ſlender ſtyle, crowned by a roundiſh ſtigma. The germen afterward becomes a roundiſh capſule with three cells, incloſing three oblong ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, which includes thoſe plants whoſe flowers have five ſtamina and one ſtyle.

The Species are,

1. Ipomoea (*Quamoclit*) foliis pinnatifidis linearibus, floribus ſubſolitariis. Hort. Cliff. 60. *Ipomoea with very narrow many-pointed leaves, and ſolitary flowers.* Quamoclit foliis tenuiter inciſis & pennatis. Tourn. Inſt. R. H. 116. *Quamoclit with narrow, cut, winged leaves.*
2. Ipomoea (*Coccinea*) foliis cordatis acuminatis, baſi angulatis, pedunculis multifloris. Hort. Upſal. 39. *Ipomoea with heart-ſhaped pointed leaves, angular at the baſe, and many flowers on a ſtalk.* Quamoclit Americana folio hederæ flore coccineo. Com. Rar. Plant. 21. *American Quamoclit with an Ivy leaf and a ſcarlet flower, commonly called Scarlet Convolvulus.*
3. Ipomoea (*Solanifolia*) foliis cordatis acutis integerrimis, floribus ſolitaris. Prod. Leyd. 430. *Ipomoea with acute, heart-ſhaped, entire leaves, and ſolitary flowers.* Quamoclit Americana ſolani folio, flore roſeo. Plum. Cat. 3. *American Quamoclit with a Nightſhade leaf, and a Roſe-coloured flower.*
4. Ipomoea (*Violacea*) foliis cordatis integerrimis, floribus confertis corollis indiviſis. Sauv. Monſp. 114. *Ipomoea with heart-ſhaped entire leaves, flowers growing in cluſters, and undivided petals.* Quamoclit foliis ampliſſimis cordiformibus. Plum. Cat. 4. *Quamoclit with large heart-ſhaped leaves.*
5. Ipomoea (*Tuberoſa*) foliis palmatis, lobis ſeptenis lanceolatis integerrimis pedunculis trifloris. Hort. Upſal. 39. *Ipomoea with hand-ſhaped leaves, compoſed of ſeven ſpear-ſhaped entire lobes, and foot-ſtalks having three flowers.* Convolvulus major heptaphyllus, flore ſulphureo odorato. Sloan. Cat. 55. *Greater ſeven-leaved*

Bindweed with a yellow ſweet flower, called Spaniſh Arbour Vine.

6. Ipomoea (*Triloba*) foliis trilobis cordatis, pedunculis trifloris. Lin. Sp. Plant. 161. *Ipomea with heart-ſhaped leaves having three lobes, and three flowers on a foot-ſtalk.* Convolvulus pentaphyllos minor, flore purpureo. Sloan. Cat. 55. *Smaller five-leaved Bindweed with a purple flower.*

7. Ipomoea (*Hepaticæfolia*) foliis palmatis, floribus aggregatis. Flor. Zeyl. 79. *Ipomoea with hand-ſhaped leaves, and flowers growing in cluſters.* Volubilis Zeylanica pes tigrinus dicta. Hort. Elth. 318. *Volubilis of Ceylon, called Tyger's-foot.*

8. Ipomoea (*Digitata*) foliis digitatis glabris floribus ſeſſilibus, caule lævi. Lin. Sp. Plant. 162. *Ipomoea with ſmooth hand-ſhaped leaves, whoſe lobes ſit cloſe, and a ſmooth ſtalk.* Convolvulus quinquefolius glaber Americanus. Pluk. Alm. 116. *Smooth five-leaved American Bindweed.*

The firſt ſort grows naturally in both Indies; in the Weſt-Indies it is called Sweet-William, and by ſome Indian Pink. It riſes with a twining ſtalk ſeven or eight feet high, ſending out many ſlender twining branches, which twiſt about any neighbouring plants for ſupport; the leaves are winged, being compoſed of ſeveral pair of very fine narrow lobes, not thicker than fine ſowing thread; they are about an inch long, of a deep green, and ſometimes are by pairs oppoſite, and at others they are alternate; the flowers come out ſingly from the ſide of the ſtalks, ſtanding upon ſlender foot-ſtalks about one inch long; they are funnel-ſhaped, having a tube an inch long, which is narrow at bottom, but gradually widens to the top, which ſpreads open flat, with five corners or angles: they are of a moſt beautiful ſcarlet colour, ſo make a fine appearance. This is an annual plant in England, but whether it is ſo in its native place I cannot tell; for as the ſeeds fall to the ground, ſo there is a ſucceſſion of young plants, which continue flowering great part of the year.

This is a tender plant, ſo will not thrive in the open air in England; it is propagated by ſeeds, which ſhould be ſown on a hot-bed in the ſpring; and as the plants will ſoon appear, they ſhould be each tranſplanted into a ſmall pot filled with light earth, before they twine about each other, for then it will be difficult to diſengage them without breaking their tops. When they are potted, they ſhould be plunged into a new hot-bed, and ſticks placed down by each plant for their ſtalks to twine about; after they have taken new root, they ſhould have a good ſhare of air in warm weather to prevent their drawing up weak; and when they are advanced too high to remain under the frame, they ſhould be removed into the tan-bed in the ſtove, where they ſhould have ſupport, for their branches will extend to a conſiderable height. They will begin to flower in June, and there will be a ſucceſſion of flowers till the end of September, and the ſeeds will ripen well in this ſituation every autumn.

The ſecond ſort grows naturally in Carolina and the Bahama Iſlands; this is alſo an annual plant in England, but is not ſo tender as the former. It hath a twining ſtalk, which riſes ſix or eight feet high, garniſhed with heart-ſhaped leaves ending in acute points, which are divided into angles at their baſe; the flowers come out from the ſide of the branches, upon ſlender foot-ſtalks, which ſupport three or four flowers of the ſame form and ſize as the former, but are not ſo deep coloured. There is a variety of this with Orange-coloured flowers, but they do not differ in any other reſpect. If the ſeeds of this ſort are ſown on a hot-bed in the ſpring, and when the plants come up, if they are gradually hardened, and afterward tranſplanted into a warm border, in favourable ſeaſons they will flower and produce good ſeeds; but moſt people raiſe the plants on a very gentle hot-bed, and tranſplant them afterward into another; by which method they are brought forward, ſo will perfect their ſeeds earlier.

The third ſort is like the ſecond, but the leaves have no angles, and the flowers are of a Roſe colour, each foot-ſtalk ſuſtaining one flower. This may be treated in the ſame manner as the ſecond ſort.

The fourth ſort grows naturally in the Weſt-Indies, where it twines about any neighbouring ſupport, and riſes ten or twelve feet high, garniſhed with large heart-ſhaped entire leaves: the flowers come out from the ſide of the branches upon ſlender foot-ſtalks, in cluſters; they are of a blue colour, and their brims are not angular as in the former ſpecies, but entire. This ſort is propagated by ſeeds, which ſhould be ſown on a hot-bed in the ſpring, and the plants afterward treated in the ſame way as is before directed for the firſt ſort, for it is too tender to thrive in the open air here.

The fifth ſort is cultivated in moſt of the iſlands in the Weſt-Indies, but is ſuppoſed to have been introduced there from the Spaniſh Main. Theſe plants riſe to a very great height, and ſend out many branches, ſo are planted to cover arbours for ſhade in the iſlands, from whence it had the appellation of Spaniſh Arbour Vine. The ſtalks of this plant are covered with a purple bark; they twine about any neighbouring ſupport, ſending out many ſide branches, ſo that one plant will cover an arbour of fifty feet long. The leaves are divided into ſeven lobes almoſt to the bottom; the flowers come out from the ſide of the ſtalks; they are large, funnel-ſhaped, of a bright yellow colour, and ſmell very ſweet; theſe are ſucceeded by large roundiſh capſules with three cells, containing one large ſeed in each, which are of a dark colour.

This is a perennial plant, but too tender to thrive in the open air in England; the ſeeds of this muſt be ſown upon a hot-bed in the ſpring, and when the plants come up, they muſt be tranſplanted into ſeparate pots, and plunged into a freſh hot-bed; but as they will ſoon grow too tall to ſtand under a frame, they ſhould be removed into the bark-ſtove, where they muſt be ſupported, otherwiſe they will twine about all the neighbouring plants. As theſe plants extend their ſhoots to a very great length, they require a tall ſtove, where they may have room to grow, without which they will never produce any flowers. I have had theſe plants ſeveral years, but have only ſeen one flower produced from them; for they grow ſo very large before they begin to have flowers, as that few of the ſtoves in England have height enough for their growth.

The ſixth ſort grows naturally in moſt of the iſlands in the Weſt-Indies; this hath a twining ſtalk, which riſes ten or twelve feet high, garniſhed with leaves divided into three lobes, which are heart-ſhaped; the foot-ſtalks ariſe from the ſide of the ſtalks, each ſuſtaining three purple flowers. This is alſo tender, ſo the plants muſt be raiſed on a hot-bed in the ſpring, and afterward planted in ſeparate pots, plunging them into another hot-bed, where they may remain till they reach the glaſſes, when they ſhould be removed into a glaſs-caſe where they may have room, and be ſcreened from the cold, but ſhould have a large ſhare of free air admitted to them in warm weather; with this treatment the plants will flower and produce ripe ſeeds.

The ſeventh ſort grows naturally in India; this riſes with a twining hairy ſtalk four or five feet high, garniſhed with hand-ſhaped leaves which are hairy, and divided at the bottom into ſeveral lobes; the flowers come out in cluſters, incloſed in a five-cornered involucrum; they are of a purpliſh colour, but ſmall, and open only in the evening, ſo make no figure. This is propagated by ſeeds, and requires the ſame treatment as the ſixth ſort.

The eighth ſort grows naturally in the Weſt-Indies; this hath a ſmooth twining ſtalk which riſes four or five feet high, garniſhed with hand-ſhaped leaves having five lobes, which ſit cloſe to the ſtalks; the flowers come out from the ſide of the ſtalks upon ſhort foot-ſtalks, which ſuſtain two or three purple flowers; theſe are ſucceeded by round tricapſular ſeed-veſſels; in each cell there is one brown ſeed.

This ſort requires the ſame treatment as the two former, with which it will produce flowers and perfect its ſeeds in England.

IRESINE. Lin. Gen. 1113. Amaranthus. Sloan. Cat. Jam. 49.

The Characters are,

It hath male and female flowers on different plants; the male flowers have an empalement compoſed of two neat ſmall leaves, and five erect, ſmall, ſpear-ſhaped petals, and five nectarii ſituated between the five erect ſtamina, which are terminated by roundiſh ſummits; the female flowers on the other plants, have the like empalement and corolla as the male, with an oval germen but no ſtyle, crowned by two roundiſh ſtigma; the empalement afterward becomes an oval capſule, incloſing woolly ſeeds.

This genus is ranged in the fifth order of Linnæus's twenty-ſecond claſs of plants, intitled Diœcia Pentandria, from their having male and female flowers on different plants, and the male flowers having five ſtamina.

We know but one Species of this genus, viz.

Iresine (*Celoſioides.*) Lin. Sp. 1456. Amaranthus panicula flavicante gracili holoſericea. Sloan. Cat. Jam. 49. *Amaranthus with ſlender yellowiſh panicles of ſilky flowers.*

This plant grows naturally in Jamaica, and moſt of the other iſlands in the Weſt-Indies, from whence I have received the ſeeds. It is perennial; the ſtalks are weak, ſo require ſupport; they riſe ten or twelve feet high, having large knots at each joint, garniſhed with oval, ſpear-ſhaped, ſmooth leaves. The ſtalks are very diffuſed, branching out on every ſide; the flowers are produced on the top, in ſlender looſe panicles, covered with a ſilky down, of a pale yellow colour; theſe appear in July and Auguſt, and in warm ſeaſons the ſeeds will ripen in the autumn.

It is propagated by ſeeds, which ſhould be ſown upon a hot-bed in the ſpring, and the plants ſhould be afterward treated in the ſame manner as hath been directed for the tender ſorts of Amaranthus, till they are grown too tall to remain in the frame, when they ſhould be removed to the bark-ſtove, plunging the pots into the tan-bed, and ſupporting the branches of the plants with a trellis to prevent their falling on other plants; in this ſituation they will produce flowers and ſeeds the ſecond year, but the plants may be continued three or four years longer.

IRIS. Tourn. Inſt. R. H. 358. tab. 186, 187, 188. Lin. Gen. Plant. 57. Flower-de-luce; in French, *Flambe.*

The Characters are,

The flowers are incloſed in ſpathæ (or ſheaths) which are permanent; the flowers are divided into ſix parts; the three outer petals are oblong, obtuſe, and reflexed, the three inner are erect, and end in acute points; theſe all join at their baſe: they have three awl-ſhaped ſtamina, which lie upon the reflexed petals, and are terminated by oblong depreſſed ſummits. Under the flower is ſituated an oblong germen, ſupporting a ſlender ſtyle, crowned by a large three-pointed ſtigma; the germen afterward becomes an oblong angular capſule with three cells, filled with large ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's third claſs, intitled Triandria Monogynia, which contains thoſe plants whoſe flowers have three ſtamina and one ſtyle.

The Species are,

1. Iris (*Pſeudoacorus*) corollis imberbibus, petalis interioribus ſtigmate minoribus, foliis enſiformibus. Hort. Cliff. *Iris with an unbearded flower, the inner petals ſmaller than the ſtigma, and ſword-ſhaped leaves.* Iris paluſtris lutea. Tabern. Icon. 643. *Yellow Marſh Flower-de-luce.*
2. Iris (*Squalens*) corollis barbatis, caule foliis longiore multifloro. Hort. Cliff. 18. *Iris with bearded flowers, and the ſtalks longer than the leaves, having many flowers.* This is the Iris vulgaris Germanica ſive ſylveſtris. C. B. P. 30. *Common German, or wild Flower-de-luce.*
3. Iris (*Aphylla*) corollis barbatis, ſcapo nudo longitudine foliorum multifloro. Prod. Leyd. 17. *Iris with a bearded flower, and a naked ſtalk the length of the leaves, with many flowers.* Iris latifolia, caule aphyllo. C. B. P. 32. *Broad-leaved Flower-de-luce, whoſe ſtalks are without leaves.*
4. Iris (*Variegata*) corollis barbatis, caule ſubfolioſo longitudine foliorum multifloro. Prod. Leyd. 17. *Iris with a bearded flower, and a leafy ſtalk the length of the leaves, with many flowers.* Iris latifolia pannonica, colore multiplici. C. B. P. 31. *Broad-leaved Hungarian Flower-de-luce of many colours.*
5. Iris (*Suſiana*) corollis barbatis, caule foliis longiore unifloro. Hort. Cliff. 18. *Iris with a bearded flower, and a ſtalk longer than the leaves, having one flower.* Iris Suſiana, flore maximo ex albo nigricante. C. B. P. 31. *Flower-de-luce with a very large flower of a black and white colour, commonly called Chalcedonian Iris.*
6. Iris (*Biflora*) corollis barbatis, caule foliis breviore trifloro. Hort. Upſal. 17. *Iris with a bearded flower, and a ſtalk ſhorter than the leaves, with three flowers.* Iris humilis major, ſaturatè purpurea biflora. Tourn. Inſt. 361. *Greater Dwarf Flower-de-luce of a dark purple colour, and having two flowers on each ſtalk.*
7. Iris (*Pumila*) corollis barbatis, caule foliis breviore unifloro. Lin. Sp. Plant. 38. *Iris with a bearded flower, and a ſtalk ſhorter than the leaves, with one flower.* Iris humilis minor, flore purpureo. Tourn. Inſt. 361. *Smaller Dwarf Flower-de-luce with a purple flower.*
8. Iris (*Germanica*) corollis barbatis, caule foliis longiore multifloro, floribus inferioribus pedunculatis. Lin. Sp. 55. *Iris with a bearded flower, a ſtalk longer than the leaves with many flowers, and the lower flowers on foot-ſtalks.* Iris Aſiatica cærulea polyanthos. C. B. P. *Blue Aſiatic Flower-de-luce with many flowers, called greater Dalmatian Iris.*
9. Iris (*Orientalis*) corollis barbatis, germinibus trigonis, foliis enſiformibus longiſſimis caule foliis longiore bifloro. Pluk. 154. *Iris with a bearded flower, a three-cornered germen, very long ſword-ſhaped leaves, and a ſtalk longer than the leaves, with two flowers.*
10. Iris (*Graminea*) corollis imberbibus, germinibus ſexangularibus, caule ancipiti, foliis linearibus. Hort. Cliff. 19. *Iris with flowers having no beards, a ſix-cornered germen, a ſtalk having flowers on both ſides, and narrow leaves.* Iris anguſtifolia prunum redolens minor. C. B. P. 33. *Smaller narrow-leaved Flower-de-luce ſmelling like Plums.*
11. Iris (*Maritima*) corollis imberbibus, caule foliis breviore trifloro, foliis lineari-enſiformibus. *Iris whoſe flowers are not bearded, the ſtalk ſhorter than the leaves, having three flowers, and narrow ſword-ſhaped leaves.* Iris anguſtifolia maritima major. C. B. P. 33. *Greater narrow-leaved maritime Flower-de-luce.*
12. Iris (*Anguſtifolia*) corollis imberbibus, caule foliis æqualibus multifloro, ſpathâ majoribus erectis. *Iris whoſe flowers have no beards, the ſtalks equal in length with the leaves, having many flowers which are larger and more erect than the ſpatha.* Iris anguſtifolia, maritima minor. C. B. P. *Smaller narrow-leaved maritime Flower-de-luce.*
13. Iris (*Bicolor*) corollis imberbibus, caule foliis longiore multifloro, germinibus ſexangularibus, foliis linearibus. *Iris whoſe flowers have no beards, the ſtalks longer than the leaves, with many flowers, a ſix-cornered germen, and very narrow leaves.* Iris anguſtifolia, bicolor. C. B. P. 33. *Narrow-leaved Flower-de-luce with two colours.*

23. Iris (*Sambucina*) corollis barbatis, caule foliis altiore multifloro, petalis deflexis planis, erećtis emarginatis. Lin. Sp. 55. *Iris with a bearded corolla, ſtalks taller than the leaves, having many flowers whoſe petals are deflexed, and the upright are indented.* Iris latifolia Germanica, ſambuci odore. C. B. P. 31.

The firſt ſort grows naturally in ditches and ſtanding waters in moſt parts of England; this is titled in the Pharmacopeia, Acorus adulterinus, or Pſeudo acorus. *Baſtard Acorus.* The roots of this are pretty thick, fleſhy, and ſpread every way near the ſurface of the ground; the leaves are ſword-ſhaped, very long, of a deep green colour, and not ſo ſtiff as thoſe of the Garden Iris; the ſtalks riſe from two to three feet high, toward the top of which grow three or four flowers one above another, which gradually ſucceed each other; they are ſhaped like the ordinary Flower-de-luce, but the three inner petals are leſs than the ſtigmas, ſo they want the three upright petals which are termed ſtandards. Theſe appear in June, and are ſucceeded by large three-cornered capſules, containing three rows of flat ſeeds.

This ſort is not cultivated in gardens, but being an officinal plant, it is here mentioned to introduce the other.

The ſecond ſort grows naturally in Germany, but has been long cultivated in the Engliſh gardens for ornament; the roots of this are very thick, fleſhy, and divided into joints, ſpreading juſt under the ſurface of the ground; they are of a browniſh colour on their outſide, but white within; the leaves ariſe in cluſters, embracing each other at their baſe, but ſpread aſunder upward in form of wings; they are a foot and a half long, and two inches broad, having ſharp edges, ending in points like ſwords; the ſtalks between theſe, which are a little longer than the leaves, having at each joint one leaf without a foot-ſtalk; theſe diminiſh in their ſize upward; the ſtalks divide into three branches, each of which produce two or three flowers one above another at diſtances, each incloſed in a ſheath; they have three large Violet-coloured petals which turn backward, and are called falls; theſe have beards near an inch long on their midrib toward their baſe, and have a ſhort arched petal which cover the beard, with three broad erećt petals of the ſame colour, called ſtandards; the ſtamina lie upon the reflexed petals. Under each flower is ſituated an oblong germen, which turns to a large three-cornered capſule with three cells, filled with large compreſſed ſeeds. This flowers in June, and the ſeeds ripen in Auguſt.

There is a variety of this with blue ſtandards and purple falls, which is titled Iris hortenſis latifolia, by Caſpar Bauhin; and one with pale purple ſtandards, another with white, and a third with a ſmaller flower, but theſe are accidental varieties which have come from ſeeds.

The third ſort has broader leaves than the laſt, the ſtalks have no leaves upon them, and are equal in length with the leaves; they have three or four large bright purple flowers, which ſtand above each other, having purpliſh ſheaths or hoods; the three bending petals or falls are ſtriped with white, from the baſe to the end of the beard; the flowers are ſucceeded by large blunt triangular capſules with three cells, filled with compreſſed ſeeds. It flowers the latter end of May, and the ſeeds ripen the beginning of Auguſt.

The fourth ſort grows naturally in Hungary; the leaves of this are like thoſe of the ſecond ſort, but are of a darker green; the ſtalks riſe as tall as the leaves, and toward the bottom are garniſhed with one leaf at each joint, whoſe baſe embrace the ſtalks; the upper part is naked, and branches into three, each having two or three flowers above one another; the three upright petals or ſtandards are yellow, and the bending petals or falls are variegated with purple ſtripes. This flowers in June, but is rarely ſucceeded by ſeeds in England.

The fifth ſort grows naturally near Conſtantinople, and in other parts of the eaſt. The leaves of this ſort are not ſo broad as thoſe of the ſecond, and are of a grayiſh colour; the ſtalks riſe two feet and a half high, ſupporting one very large flower; the three upright petals are almoſt as broad as a hand, but very thin, of mixed black and white ſtripes; the three bending petals or falls are of a darker colour, from whence ſome gardeners have called it the Mourning Iris. This flowers the latter end of May, or the beginning of June, but never has any ſeeds in England.

The ſixth ſort hath broad leaves like thoſe of the ſecond ſort, but ſhorter; the ſtalks riſe nine or ten inches high, branching into two or three at the top, each ſuſtaining two deep purple flowers. This flowers in May, but is not ſucceeded by ſeeds in England.

The ſeventh ſort hath narrower and ſhorter leaves than the former; the ſtalks are ſhorter than the leaves, and ſupport one flower on the top, of a light purple colour. This flowers the beginning of May, but rarely produces ſeeds in this country. There are two or three varieties of this, which differ in the colour of their flowers.

The eighth ſort hath the largeſt leaves of any of the Flower-de-luce, they are of a grayiſh colour and ſpread wide, embracing each other at their baſe, where they are purpliſh. The ſtalks riſe near four feet high, and divide into ſeveral branches, each ſupporting three or four flowers above each other at diſtances, covered with a thin ſheath; the three bending petals or falls, are of a faint purple inclining to blue, with purple veins running lengthways; the beard is yellow, and the three erećt petals or ſtandards are of a bright blue, with ſome faint purple ſtripes, the flowers have an agreeable ſcent. They appear the latter end of June, but are ſeldom ſucceeded by ſeeds in England.

The ſeeds of the ninth ſort were brought from Carniola, by the Right Rev. Dr. Pocock, Biſhop of Oſſory, who found the plants growing there naturally: theſe were ſown in the Chelſea garden, where they ſucceeded very well, and the plants have been ſince communicated to many curious gardens in Europe.

This plant hath a thick fleſhy root, divided into many knots or tubers, which ſpread and multiply in the ground; theſe ſend out many ſtrong, thick, fleſhy fibres, which ſtrike deep in the earth, putting out ſeveral ſmaller fibres from their ſides. From theſe roots ariſe cluſters of flat ſword-ſhaped leaves of a deep green colour, which are more than three feet long, and little more than one inch broad in the broadeſt part, ending in points; theſe leaves are connected together at their baſe into ſeveral heads or bundles, wrapping over each other; and between theſe ariſe the flower-ſtalks, which grow four feet high and are jointed, having very long ſpathæ or ſheaths at each of the upper joints, which include the flowers. Theſe ſtalks generally ſuſtain two flowers, one coming out of each ſheath or ſpatha; theſe are permanent, and when the flowers are paſt, cloſely cover the ſeed-veſſel. The flowers are divided into nine leaves, three of theſe ſtand erect, which are white, and ſix turn down, which are joined together at their baſe, the lower ſpreading out into a broad, obtuſe, reflexed fall, having a beard which is of a bright yellow colour; the upper ſegment is arched over the lower, ſo as to form a ſort of lip, which is reflexed backward; under theſe is ſituated an oblong three-cornered germen, which afterward becomes an oblong, ſwollen, three-cornered ſeed-veſſel, ending in a long point, which opens into three longitudinal cells, in which the ſeeds are ranged; theſe are angular and compreſſed. This plant flowers the latter end of June, or the beginning of July, and the ſeeds ripen in the autumn. It is very hardy, and thrives well in the open air without any protection. The leaves decay to the root in the autumn, and new ones ariſe in the ſpring. The roots alſo propagate very faſt, when they are in a light moiſt ſoil, ſo that it may ſoon be had in plenty, without waiting for plants from ſeeds.

The tenth ſort grows naturally in Auſtria; this hath narrow, flat, Graſs-like leaves, about a foot long, of a light green colour; between theſe ariſe the ſtalks about ſix inches high, having two narrow green leaves, which are much longer than the ſtalks; theſe ſtalks ſuſtain two or three flowers, which are ſmaller than any of the former ſpecies; the petals have no beards, but have a broad yellow line adorned with purple ſtripes; the three falls are of a light purple colour ſtriped with blue, and have a convex ridge running longitudinally, the other are of a reddiſh purple variegated with violet; they have a ſcent like freſh Plums. It flowers in July, and is ſucceeded by ſeed-veſſels which are ſhort, having three borders or wings running lengthways, opening in three cells, which are filled with angular ſeeds, which ripen in September.

The eleventh ſort grows naturally near the ſea, in the ſouth of France, and in Italy. This hath narrow ſword-ſhaped leaves, little more than a foot long, of a deep green colour; the ſtalks do not riſe ſo tall as the leaves; they ſuſtain at the top two or three flowers which ſtand near together; they are of a bright purple colour with very deep falls, and the three ſtandards are blue; the bending petals have no beards, but inſtead of that white broad ſtripes through the middle. This flowers in July, and the ſeeds ripen in September.

The twelfth ſort hath narrower leaves than the former, but of the ſame deep green colour; the ſtalks do not riſe higher than the leaves, and ſupport two or three flowers, which have long permanent empalements ſtanding erect, which cover the ſeed-veſſel till the ſeeds are ripe; the flowers are ſmaller, and of a paler colour than thoſe of the eleventh ſort.

The thirteenth ſort has very narrow, long, Graſs-like leaves, of a light green; the ſtalks riſe two feet and a half high, ſuſtaining three or four flowers above each other, which have blue falls, and purple ſtandards ſtriped with pale blue lines. This flowers in July, and the ſeeds ripen at Michaelmas.

The fourteenth ſort grows naturally in Germany; this hath leaves like thoſe of the eleventh ſort, which, when broken, have a diſagreeable ſcent; but this is accidental, and not common to all the plants; the ſtalks of this are taper, and riſe a little above the leaves, and ſuſtain three or four flowers one above another, which have light blue ſtandards, and purple variegated falls without beards; inſtead of which, they have a broad white line in the middle; theſe are ſucceeded by ſhort thick capſules, which have ſcarce any angles, opening in three cells, which are filled with angular ſeeds. It flowers in July, and the ſeeds ripen in September.

The fifteenth ſort has narrower leaves than thoſe of the ſecond, of a pale green colour, and not ſo ſtiff; the ſtalks are equal in height with the leaves, and branch out on both ſides with long foot-ſtalks, each ſuſtaining one pretty large yellow flower, incloſed in a long two-leaved ſheath; at each joint where the foot-ſtalks come out there is a ſingle leaf, which embraces the ſtalks with their baſe. This flowers in June, but rarely produces ſeeds in this country.

There are two varieties of this ſort, one with a ſulphur-coloured, and the other with a variegated flower, which are ſuppoſed to be only varieties which have been accidentally produced from ſeeds.

The ſixteenth ſort hath broad ſword-ſhaped leaves about eight inches long; the ſtalks riſe about the ſame height with the leaves, and divide into two or three foot-ſtalks, each ſuſtaining two or three flowers one above another, which have yellow ſtandards, and the falls are variegated with dark ſtripes. This flowers in June, but does not produce ſeeds here.

The ſeventeenth ſort grows naturally in North America; this hath tufted fibrous roots, from which ariſe many Graſs-like leaves about nine inches long; from between theſe come out the ſtalks, which are ſhorter than the leaves, ſupporting one purple flower with blue ſtandards. This ſort flowers in May, but ſeldom produces ſeeds in England.

The eighteenth ſort grows alſo in North America; this hath narrow ſword-ſhaped leaves about a foot long, of a light green colour; the ſtalks riſe a little above the leaves, they are taper, and ſupport two or three flowers one above another; the ſtandards are of a light blue, and the falls are purple variegated, with a broad white line inſtead of a beard through the middle. The germen, which is ſituated under the flower, is three-cornered below, but taper toward the top. This flowers in June, and often produces ſeeds here.

The nineteenth ſort grows naturally in moiſt places in many parts of England, ſo is ſeldom admitted into gardens. This hath thick tufted fibrous roots; the leaves are of a Graſs-green, ſword-ſhaped, and when broken emit a ſtrong odour, not much unlike that of hot roaſt beef at the firſt ſcent, but if ſmelt too cloſe, becomes diſagreeable. It is generally called ſtinking Gladwyn in England; the ſtalks riſe about the ſame height with the leaves, ſupporting two ſmall flowers, of a purple colour, variegated. It flowers in June, and the ſeeds ripen in autumn.

The twentieth ſort grows naturally in Auſtria and Bohemia; this hath narrow ſword-ſhaped leaves near a foot and a half long, of a dark green colour; the flower-ſtalks riſe above the leaves, and ſupport two or three flowers with light blue ſtandards, and deep blue falls, with a broad ſtripe of white, inſtead of the beard. This flowers in July, and the ſeeds ripen in September.

There are ſeveral varieties of theſe flag or ſword-leaved Iriſes, which chiefly differ in the colour of their flowers, ſo are not to be regarded as diſtinct ſpecies; thoſe which are here enumerated are ſuppoſed to be ſpecifically different, great part of them I have cultivated by ſeeds, and found them conſtantly produce the ſame as the parent plants.

All theſe ſorts are generally propagated by parting of their roots, which moſt of them multiply faſt enough. The beſt time to remove and part the roots is in autumn, that they may get good root before the ſpring, otherwiſe they will not flower ſtrong the following ſummer. All thoſe ſorts which ſpread much at their roots ſhould be tranſplanted every other year, to keep them within bounds, otherwiſe they will ſpread ſo much as to become troubleſome, eſpecially if they are planted near other flowers; indeed, the large growing kinds are moſt of them too ſpreading for the flower-garden, ſo are only fit to fill up the ſpaces between trees and ſhrubs in large plantations, where they will have a good effect during the time of their flowering.

The fifth, ſixth, ſeventh, tenth, eleventh, ſixteenth, ſeventeenth and eighteenth ſorts, grow in leſs compaſs, ſo may be admitted into the large borders, or in clumps of flowers in the pleaſure-garden, where they will add to the variety. The fifth ſort ſhould have a warmer ſituation, being a little tender, but all the other ſorts will grow in almoſt any ſoil or ſituation; theſe may all be propagated by ſeeds, which ſhould be ſown ſoon after they are ripe, then the plants will come up the following ſpring; but if the ſeeds are ſown in the ſpring, they will lie a year in the ground before they vegetate: when the plants come up they muſt be kept clean from weeds, and the following autumn ſhould be tranſplanted into beds at ten inches or a foot diſtance, where they may remain till they flower, which will be the ſecond ſummer after tranſplanting; but as moſt of the ſorts are ſo eaſily propagated by their roots, few people care to wait for ſeedling plants, unleſs of thoſe ſorts which are ſcarce.

The twenty-firſt ſort grows naturally in the iſlands of the Archipelago; this hath a tuberous knobbed root, from which ariſe five or ſix long, narrow, four-cornered leaves, between which ariſe the ſtalk, which ſupports one flower, ſhaped like thoſe of the Iris, but ſmall, and of a dark purple colour. This flowers in April, but does not produce ſeeds in England. It is propagated by the roots, which ſend out offſets; theſe may be taken up and tranſplanted when their leaves decay, but ſhould not be kept too long out of the ground. If theſe are planted in a deep looſe ſoil, the roots will run down, and be loſt in a few years where they are not diſturbed, ſo they ſhould be annually tranſplanted, and have a ſhallow ſoil; they are hardy in reſpect to cold, and require no farther care but to keep them clean from weeds.

The twenty-ſecond ſort grows naturally in the warm parts of Europe, but is hardy enough to thrive in the open air in England; the leaves of this ſort are broad, of a pale green colour; the flower-ſtalks riſe taller than the leaves, ſupporting one or two white flowers which ſit cloſe to the ſtalks. The roots of this are uſed in medicine, and is uſually called Sweet Iris.

The twenty-third ſort hath broad leaves, of a deeper green than thoſe of the laſt ſort. The ſtalks riſe much above the leaves, each having four or five flowers, which have a yellow ground, variegated with dark brown ſtripes, and have a ſcent like Elder; the two ſorts flower the latter end of May, or beginning of June.

They are ſo hardy as to thrive as well as the ſecond ſort in the open air in this country, and may be propagated by parting of their roots, or by ſeeds, in the ſame way as is directed for that ſort.

ISATIS. Tourn. Inſt. R. H. 211. tab. 100. Lin. Gen. Plant. 738. Woad; in French, *Paſtel.*

The CHARACTERS are,

The empalement of the flower is compoſed of four oval coloured leaves, which ſpread open and fall away. The flower hath four oblong petals, placed in form of a croſs, which are narrow at their baſe, but broad and obtuſe at their ends. It hath ſix ſtamina, four of which are as long as the petals, the other two are ſhorter; theſe are terminated by oblong lateral ſummits. It has an oblong compreſſed germen, the length of the two ſhorter ſtamina, crowned by an obtuſe ſtigma. The germen becomes an oblong compreſſed pod with one cell, opening with two valves, incloſing one oval compreſſed ſeed in the center.

This genus of plants is ranged in the ſecond ſection of Linnæus's fifteenth claſs, intitled Tetradynamia Siliquoſa, which includes the plants whoſe flowers have four long and two ſhorter ſtamina, and their ſeeds in pods.

The SPECIES are,

1. ISATIS (*Tinctoria*) foliis radicalibus oblongo-ovatis obtuſis integerrimis, caulinis ſagittatis ſiliculis oblongis. *Woad with oblong, oval, blunt, entire leaves at bottom, but thoſe on the ſtalks arrow-pointed, and oblong pods.* Iſatis ſativa vel latifolia. C. B. P. 113. *Broad-leaved cultivated Woad.*
2. ISATIS (*Dalmatica*) foliis radicalibus lanceolatis crenatis, caulinis lineari-ſagittatis, ſiliculis brevioribus emarginatis. *Woad with ſpear-ſhaped lower leaves which are ſlightly crenated, thoſe on the ſtalks very narrow and arrow-pointed, and ſhorter indented pods.* Iſatis Dalmatica major. Bobart. *Greater Woad of Dalmatia.*
3. ISATIS (*Luſitanica*) foliis radicalibus crenatis, caulinis ſagittatis, pedunculis ſubtomentoſis. Lin. Sp. 936. *Woad with crenated lower leaves, thoſe on the ſtalks halbert-ſhaped, and the foot-ſtalks of the flowers woolly.* Iſatis ſylveſtris, minor Luſitanica. H. L. App. *Smaller wild Portugal Woad.*
4. ISATIS (*Ægyptiaca*) foliis omnibus dentatis. Lin. Sp. 937. *Woad whoſe leaves are all indented.*

The firſt ſort is cultivated in ſeveral parts of England for the purpoſes of dyeing, this being uſed as a foundation for many of the dark colours.

This is a commodity well worth propagating in all places where the land is ſuitable for it, which muſt be a pretty ſtrong ſoil, but not too moiſt.

The plant is biennial, in which it differs from the third and fourth ſort, which are annual. The lower leaves of this are of an oblong oval figure, and pretty thick conſiſtence, when growing in a proper ſoil; they are narrow at their baſe, but broad above, and end in obtuſe roundiſh points, entire on their edges, and of a lucid green. The ſtalks riſe near four feet high, dividing into ſeveral branches, garniſhed with arrow-ſhaped leaves, ſitting cloſe to the ſtalks; the ends of the branches are terminated by ſmall yellow flowers, in very cloſe cluſters, which are compoſed of four ſmall petals, placed in form of a croſs; theſe are ſucceeded by pods ſhaped like a bird's tongue, half an inch long, and one eighth of an inch broad, which when ripe turn black, and open with two valves, having one cell, in which is ſituated a ſingle ſeed. It flowers in July, and the ſeeds ripen the beginning of September.

The third ſort has been ſuppoſed to be the ſame ſpecies as the firſt, only differing by culture; but I have propagated both ſorts more than forty years, and have not found either of them alter; there are alſo very eſſential differences between the two plants, particularly in the ſhape of the under leaves, which in the wild ſort are narrow and ſpear-ſhaped, and thoſe on the ſtalks are not more than half the breadth of thoſe of the cultivated Woad. The ſtalks do not branch ſo much, and the pods are narrower than thoſe of the other ſort, nor do the roots abide ſo long, for they generally die the ſame year.

The ſecond ſort grows naturally in Dalmatia; this is a biennial plant; the lower leaves are ſpear-ſhaped, and crenated on their edges, but thoſe on the ſtalks are very narrow and arrow-pointed. The ſtalks branch more than thoſe of the firſt ſort, and riſe higher. The flowers are larger, and of a brighter yellow colour. The ſeed-veſſels are ſhorter, and broader at their ends, which are indented. Theſe plants all flower in July, and their ſeeds ripen in September.

The fourth ſort grows naturally in Egypt, and is an annual plant, which is too tender to thrive in the open air in England, therefore the ſeeds ſhould be ſown on a hot-bed in the ſpring; and when the plants are fit to remove they muſt be tranſplanted on a freſh hot-bed to bring them forward, but as ſoon as they have taken new root, they ſhould have a large ſhare of freſh air admitted to them daily, to prevent their being drawn up weak. In this bed they may remain five or ſix weeks, by which time they will be fit to tranſplant into pots, which ſhould be carefully performed, not to let the earth fall from their roots; the pots ſhould alſo be plunged into a moderate hot-bed, giving the plants plenty of air at all times when the weather will permit, and ſupporting their ſtalks, which will otherwiſe trail on the ground; with this management the plants will flower in June, and ripen their ſeeds in September.

The three laſt ſorts are not cultivated for uſe, ſo are only preſerved in botanic gardens for the ſake of variety; the ſecond and third ſorts are propagated by ſeeds, which ſhould be ſown in autumn; and when the plants come up, they muſt be thinned, leaving them ſix inches apart; afterward they muſt be kept clean from weeds: the ſummer following they will flower and produce ripe ſeeds, after which theſe ſorts ſoon decay; the roots of the firſt ſort will live another year. The firſt ſort which is propagated for uſe, is ſown upon freſh land which is in good heart, for which the cultivators of Woad pay a large rent; they generally chuſe to have their land ſituated near great towns, where there is plenty of dreſſing, but they never ſtay long on the ſame ſpot, for the beſt ground will not admit of being ſown with Woad more than twice; for if it is oftener repeated, the crop ſeldom pays the charges of culture, &c.

Thoſe who cultivate this commodity, have gangs of people, who have been bred to this employment, ſo that whole families travel about from place to place, wherever their principal fixes on land for the purpoſe; but theſe people go on in one track, juſt as their predeceſſors taught them; nor have their principals deviated much from the practice of their anceſtors, ſo that there is a large field for improvement, if any of the cultivators of Woad were perſons of genius, and could be prevailed on to introduce the garden culture ſo far as it may be adapted to this plant; this I know from experience, having made numbers of trials in the culture of this plant, therefore I ſhall inſert them here for the benefit of thoſe who may have ingenuity enough to ſtrike out of the old beaten track.

As the goodneſs of Woad conſiſts in the ſize and fatneſs of the leaves, the only method to obtain this, is by ſowing the ſeed upon ground at a proper ſeaſon, and allow the plants proper room to grow, as alſo to keep them clean from weeds; which, if permitted to to grow, will rob the plants of their nouriſhment. The method practiſed by ſome of the moſt ſkilful kitchen-gardeners in the culture of Spinach, would be a great improvement to this plant, for ſome of them have improved the round-leaved Spinach ſo much by culture, as to have the leaves more than ſix times the ſize they were formerly; and their fatneſs has been in the ſame proportion, upon the ſame land, which has been effected by thinning of the plants when young, and keeping the ground conſtantly clean from weeds; but to return to the culture of Woad.

After having made choice of a proper ſpot of land, which ſhould not be too light and ſandy, nor over ſtiff and moiſt, but rather a gentle hazel loam, whoſe parts will eaſily ſeparate: the next is to plough this up juſt before winter, laying it in narrow high ridges, that the froſt may penetrate through the ridges, to mellow and ſoften the clods; then in the ſpring plough it again croſſway, laying it again in narrow ridges; after it has lain ſome time in this manner, and the weeds begin to grow, it ſhould be well harrowed to deſtroy them; this ſhould be twice repeated while the weeds are young, and if there are any roots of large perennial weeds, they muſt be harrowed out, and carried off the ground. In June the ground ſhould be a third time ploughed, when the furrows ſhould be narrow, and the ground ſtirred as deep as the plough will go, that the parts may be as well ſeparated as poſſible; and when the weeds appear again, the ground ſhould be well harrowed to deſtroy them. Toward the end of July, or the beginning of Auguſt, it ſhould be ploughed the laſt time, when the land ſhould be laid ſmooth, and when there is a proſpect of ſhowers, the ground muſt be harrowed to receive the ſeeds, which ſhould be ſown either in rows with the drill plough, or in broad-caſt, after the common method; but it will be proper to ſteep the ſeeds one night in water before they are ſown, which will prepare them for vegetation: if the ſeeds are ſown in drills with a plough, they will be covered by an inſtrument fixed to the plough for that purpoſe; but thoſe which are ſown broad-caſt in the common way, muſt be well harrowed in. If the ſeeds are good and the ſeaſon favourable, the plants will appear in a fortnight, and in a month or five weeks after will be fit to hoe; for the ſooner this is performed when the plants are diſtinguiſhable, the better they will thrive, and the weeds being then young, will be ſoon deſtroyed. The method of hoeing theſe plants is the ſame as for Turneps, with this difference only, that theſe plants need not be thinned ſo much; for at the firſt hoeing, if they are ſeparated to the diſtance of three or four inches, and at the laſt to ſix inches, it will be ſpace enough for the growth of the plants; if this is carefully performed, and in dry weather, moſt of the weeds will be deſtroyed: but as ſome of them may eſcape in this operation, and young weeds will ariſe, ſo the ground ſhould be a ſecond time hoed in October, always chuſing a dry time for this work; at this ſecond operation, the plants ſhould be ſingled out to the diſtance they are to remain. After this the ground will be clean from weeds till the ſpring, when young weeds will come up, therefore about a fortnight in April will be a good time to hoe the ground again, when the weeds will be young, ſo may be performed in leſs than half the time it would require if the weeds were permitted to grow large, and the ſun and wind will much ſooner kill them; this hoeing will alſo ſtir the ſurface of the ground, and greatly promote the growth of the plants; if it is performed in dry weather, the ground will be clean till the firſt crop of Woad is gathered, after which it muſt be again well cleaned; if this is carefully repeated, after the gathering of each crop, the land will always lie clean, and the plants will thrive the better. The expence of the firſt hoeing will be about ſix ſhillings per acre; and for the after-hoeings half that price will be ſufficient, provided they are performed when the weeds are young; for if they are ſuffered to grow large, it will require more labour, nor can it be ſo well performed; therefore it is not only the beſt huſbandry to do this work ſoon, but it will be found the cheapeſt method; for the ſame number of men will hoe a field of ten acres three times, when it is performed while the weeds are young, as is required to hoe it twice only, becauſe the weeds have longer time to grow between the operations.

If the land in which the ſeed is ſown, ſhould have been in culture before for other crops, ſo not in good heart, it will require dreſſing before it is ſown, in which caſe rotten ſtable dung is preferable to any other; but this ſhould not be laid on till the laſt ploughing before the ſeeds are ſown, and not ſpread but as the land is ploughed, that the ſun may not exhale the goodneſs of it, which in ſummer is ſoon loſt, when ſpread on the ground. The quantity ſhould not be leſs than twenty loads to each acre, which will keep the ground in heart till the crop of Woad is ſpent.

The time for gathering the crop is according to the ſeaſon, but it ſhould be performed as ſoon as the leaves are fully grown, while they are perfectly green; for when they begin to change pale, great part of their goodneſs is over; for the quantity will be leſs, and the quality greatly diminiſhed.

If the land is good, and the crop well huſbanded, it will produce three or four gatherings, but the two firſt are the beſt; theſe are commonly mixed together in the manufacturing of it, but the after-crops are always kept ſeparate; for if theſe are mixed with the other, the whole will be of little value. The two firſt crops will ſell from twenty-five to thirty pounds a ton; but the latter will not bring more than ſeven or eight pounds, and ſometimes not ſo much.

An acre of land will produce a ton of Woad, and in good ſeaſons near a ton and a half.

When the planters intend to ſave the ſeeds, they cut three crops of the leaves, and then let the plants ſtand till the next year for ſeed; but if only one crop is cut, and that only of the outer leaves, letting all the middle leaves ſtand to nouriſh the ſtalks, the plants will grow ſtronger, and produce a much greater quantity of ſeeds.

Theſe ſeeds are often kept two years, but it is always beſt to ſow new ſeeds when they can be obtained. The ſeeds ripen in Auguſt; when the pods turn to a dark colour, the ſeeds ſhould be gathered; it is beſt done by reaping the ſtalks in the ſame manner as Wheat, ſpreading the ſtalks in rows upon the ground, and in four or five days the ſeeds will be fit to threſh out, provided the weather is dry; for if it lies long, the pods will open and let out the ſeeds.

There are ſome of the Woad planters who feed down the leaves in winter with ſheep, which is a very bad method; for all plants which are to remain for a future crop, ſhould never be eaten by cattle, for that greatly weakens the plants; therefore thoſe who eat down their Wheat in winter with ſheep are equally blameable.

ISOPYRUM. Lin. Gen. Plant. 621. Helleborus. Amman.

The Characters are,

The flower has no empalement. It hath five equal oval petals, which fall off, and five ſhort tububulous nectarii, ſituated within the petals, divided at their brim into three lobes, the middle one being the largeſt. It hath a great number of ſhort hairy ſtamina, terminated by ſingle ſummits, and ſeveral oval germen, with ſingle ſtyles of the ſame length, crowned by an obtuſe ſtigma the length of the ſtamina. The germen afterward become ſo many recurved capſules with one cell, filled with ſmall ſeeds.

This genus of plants is ranged in the ſeventh ſection of Linnæus's thirteenth claſs, intitled Polyandria Polygynia, which includes thoſe plants whoſe flowers have many ſtamina and ſtyles.

The Species are,

1. Isopyrum (*Fumaroides*) ſtipulis ſubulatis, petalis acutis. Hort. Upſal. 157. *Iſopyrum with awl-ſhaped ſtipulæ, and acute petals.* Helleborus fumariæ foliis. Amman. Ruth. 57. tab. 12. *Hellebore with Fumitory leaves.*
2. Isopyrum (*Thalictroides*) ſtipulis ovatis, petalis obtuſis. Lin. Sp. Plant. 557. *Iſopyrum with oval ſtipulæ, and obtuſe petals.* Ranunculus nemoroſus, thalictri folio. C. B. P. 178. *Wood Crowsfoot with a Meadow Rue leaf.*
3. Isopyrum (*Aquilegioides*) ſtipulis obſoletis. Lin. Sp. Plant. 557. *Iſopyrum with obſolete ſtipulæ.* Aquilegia montana, flore parvo, thalictri folio. C B. P. 144. *Mountain Columbine with a ſmall flower, and Meadow Rue Leaf.*

The firſt ſort grows naturally in Siberia, from whence the ſeeds were ſent to the Imperial garden at Peterſburgh, and the late Dr. Amman, profeſſor of botany there, ſent me part of the ſeeds; this is an annual plant, which ſeldom riſes more than three or four inches high. The leaves are ſhaped like thoſe of Fumitory; they are ſmall, and of a gray colour. The ſtalk is naked to the top, where there is a circle of leaves juſt under the flowers. The flowers are ſmall, of an herbaceous colour on their outſide, but yellow within, having five acute petals, and as many honey glands, with a great number of ſtamina which are ſhorter than the petals, and ſeveral reflexed moon-ſhaped germen, having ſo many ſingle ſtyles, crowned by obtuſe ſtigmas. The flowers are ſucceeded by many recurved ſeed-veſſels with one cell, filled with ſmall ſhining black ſeeds. It flowers the beginning of April, and the ſeeds ripen in May, then the plants decay.

The ſeeds of this plant ſhould be ſown in a ſhady border ſoon after they are ripe, for when they are kept long out of the ground, they ſeldom grow the firſt year; therefore when the ſeeds are permitted to ſcatter, they ſucceed better than thoſe which are ſown, and the plants will require no other care but to keep them clean from weeds; as there is no great beauty in this plant, ſo a ſmall patch or two of them in any ſhady part of the garden, by way of variety, will be ſufficient.

The ſecond and third ſorts were ſent me from Verona, near which place they grow naturally. The ſecond ſort hath leaves very like thoſe of the ſmalleſt Meadow Rue. The ſtalks riſe four or five inches high, ſupporting a few ſmall white flowers, with obtuſe petals, containing many ſmall ſeeds. It flowers the latter end of March, and the ſeeds ripen in May.

The third ſort hath leaves like the ſecond, but a little larger, and of a greener colour. The ſtalks riſe about ſix inches high, ſupporting two or three ſmall white flowers, ſhaped like thoſe of the ſecond ſort; theſe are ſucceeded by recurved ſeed-veſſels, filled with ſmall ſeeds. It flowers in April, and the ſeeds ripen in June.

Both theſe plants delight in a moiſt ſhady ſituation; they are propagated by ſeeds in the ſame way as the firſt ſort, but theſe will live two or three years.

ISORA. See Helicteres.

ITEA. Lin. Gen. Plant. 243. Flor. Virg. 143. Diconangia. Mitch. Gen. 5.

The Characters are,

The empalement of the flower is ſmall, permanent, and erect, ending in five acute points. The flower has five petals, which are inſerted in the empalement. It hath five awl-ſhaped ſtamina inſerted in the empalement, which are as long as the petals, terminated by roundiſh ſummits, and an oval germen ſupporting a cylindrical ſtyle, which is permanent, crowned by an obtuſe ſtigma. The germen afterward becomes a long oval capſule, with the ſtyle at the top, having one cell filled with ſmall ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, which includes thoſe plants whoſe flowers have five ſtamina and one ſtyle.

We have but one Species of this genus, viz.

Itea (*Virginica.*) Flor. Virg. 143. We have no Engliſh title for this plant.

This ſhrub grows in moiſt ſoils in ſeveral parts of North America, where it riſes to the height of ſix or ſeven feet, ſending out many branches from the ground upward, garniſhed with ſpear-ſhaped leaves placed alternately, ſlightly ſawed on their edges, which are reflexed, veined, and of a light green. At the extremity of the ſame year's ſhoots, in the month of July, are produced fine ſpikes of white flowers, three or four inches long, erect; and when theſe ſhrubs are in vigour, they will be entirely covered with theſe ſpikes of flowers, ſo that they make a fine appearance at their ſeaſon of flowering.

This ſhrub is now pretty common in England; but the garden where I have ſeen it in the greateſt vigour, is that of his late Grace the Duke of Argyle, at Whitton, near Hounſlow, where the ſoil agrees ſo well with this plant, that it thrives and flowers there as well as in its native country.

This ſhrub will live in the open air in England, the cold never injuring it, but it will not thrive upon dry gravelly ground, being very apt to die in ſuch places in the ſummer ſeaſon. It is propagated by layers, which, if laid down in the autumn, will put out roots ſo as to be fit to remove by the following autumn; when they may be tranſplanted into a nurſery, or to the place where they are to remain. This ſhrub flowers at a ſeaſon when there are few others in beauty, ſo it is the more valuable on that acount.

IVA. Lin. Gen. 1059. Tarconanthus. Vail. Act. Par. 1719.

The Characters are,

It hath male and female flowers in the ſame plant; the flowers have a roundiſh permanent empalement, including ſeveral florets, which are convex; the male flowers have one petal, which is funnel-ſhaped, and indented in five parts at the brim; theſe are ſituated in the diſk; they have five briſtly ſtamina, terminated by erect ſummits, approach-

ing each other; the female half florets have neither petal or ſtamina; they have an oblong germen ſupporting two hair-like ſtyles, crowned with acute ſtigmas. The empalement afterward becomes the capſule, including one naked ſeed.

This genus of plants is ranged in the fifth ſection of Linnæus's twenty-firſt claſs, intitled Monœcia Pentandria, from the plants having male and female florets, and the male florets having five ſtamina.

The Species are,

1. Iva (*Annua*) foliis lanceolato-ovatis, caule herbaceo. Hort. Upſal. 285. *Ivy with oval ſpear-ſhaped leaves and an herbaceous ſtalk.* Tarconanthus foliis cordatis ſerratis trinervis. Prod. Leyd. 538.
2. Iva (*Fruteſcens*) foliis lanceolatis, caule fruticoſo. Amœn. Acad. 3. p. 25. *Iva with ſpear-ſhaped leaves and a ſhrubby ſtalk.* Agerato affinis, Peruviana fruteſcens. Pluk. Alm. 12.

The firſt ſort grows naturally in many parts of the Weſt-Indies; it is an annual plant, with an herbaceous ſtalk, which riſes from two to three feet high, ſending out ſeveral branches from the ſides, which are garniſhed with oval ſpear-ſhaped leaves, having three deep longitudinal veins, aad are ſawed on their edges; the ſtalks and branches are terminated by ſmall cluſters of pale blue flowers, which appear in July, and are ſucceeded by ſeeds which ripen in the autumn.

This is propagated by ſeeds, which ſhould be ſown in the ſpring upon a moderate hot-bed: and when the plants are fit to remove, they ſhould be tranſplanted on another hot-bed to bring them forward, treating them in the ſame way as is directed for Impatiens, with which management the plants will flower and perfect their ſeeds.

The ſecond ſort has been long an inhabitant of the Engliſh gardens, where it has been known by the title of Jeſuits Bark-tree. It hath ſlender ligneous branches which riſe eight or ten feet high, garniſhed with ſpear-ſhaped ſawed leaves; the branches (in warm ſeaſons) are terminated by ſmall cluſters of flowers, of a pale purple colour, which appear the latter end of Auguſt, but are not ſucceeded by ſeeds in England.

This ſhrub was ſome years paſt preſerved in green-houſes, being ſuppoſed too tender to live through the winter in the open air; but late trials have made it appear, that the ordinary winters in England ſeldom hurt it, provided it is planted in a dry ſoil and a ſheltered ſituation. It is propagated in the nurſery-gardens about London for ſale, and if the branches are layed into the ground in the ſpring, they will put out roots in ſix months; or if cuttings are planted in a ſhady border in May, they will take root.

JUDAICA ARBOR. See Cercis.

JUGLANS. Lin. Gen. Plant. 950. Nux. Tourn. Inſt. R. H. 581. tab. 346. Walnut; in French, *Noiſetier.*

The Characters are,

It hath male and female flowers at ſeparate diſtances on the ſame tree. The male flowers are diſpoſed in an oblong rope, or katkin, which is cylindrical and imbricated, with ſpaces between the ſcales; each ſcale has one flower, with one petal fixed in the outer center, toward the outſide of the ſcale. The petal is divided into ſix equal parts; in the center is ſituated many ſhort ſtamina, terminated by erect acute ſummits. The female flowers grow in ſmall cluſters, ſitting cloſe to the branches; theſe have a ſhort, erect, four-pointed empalement, ſitting on the germen, and an acute erect petal, divided into four parts. Under the empalement ſits a large oval germen, ſupporting two ſhort ſtyles, crowned by large reflexed ſtigmas. The germen afterward becomes a large oval dry berry, with one cell, incloſing a large oval nut with netted furrows, whoſe kernel hath four lobes, which are variouſly furrowed.

This genus of plants is ranged in the eighth ſection of Linnæus's twenty-firſt claſs, intitled Monœcia Polyandria, including thoſe plants which have male and female flowers on the ſame plant, and the male flowers have many ſtamina.

The Species are,

1. Juglans (*Regia*) foliolis ovalibus glabris ſubſerratis ſubæqualibus. Hort. Cliff. 449. *Walnut with oval ſmall leaves or lobes, which are ſmooth, ſawed, and equal.* Nux juglans ſive Regia vulgaris. C. B. P. 417. *Common Walnut.*
2. Juglans (*Nigra*) foliolis quindenis lanceolatis ſerratis, exterioribus minoribus gemmulis ſuper axillaribus. Lin. Sp. 1415. *Walnut-tree with ſpear-ſhaped lobes which are ſharply ſawed, the middle being the largeſt.* Nux juglans Virginiana nigra. H. L. 452. *Black Virginia Walnut.*
3. Juglans (*Oblonga*) foliolis cordato-lanceolatis infernè nervoſis, pediculis foliorum pubeſcentibus. *Walnut with heart ſpear-ſhaped lobes, having many veins on their under ſide, and downy foot-ſtalks to the leaves.* Juglans nigra, fructu oblongo profundiſſime inſculpto. Cat. Hort. Chelſ. *Black Virginia Walnut, with an oblong fruit very deeply furrowed.*
4. Juglans (*Alba*) foliolis lanceolatis ſerratis, exterioribus latioribus. Lin. Sp. Plant. 997. *Walnut with ſpear-ſhaped ſawed lobes, the outer being the broadeſt.* Nux juglans alba Virginienſis. Park. Theat. 1414. *White Virginia Walnut called Hickery Nut.*
5. Juglans (*Glabra*) foliolis cuneiformibus ſerratis, exterioribus majoribus. *Walnut with wedge-ſhaped lobes which are ſawed, the outer beiug the largeſt.* Juglans alba fructu minori cortice glabro. Clayt. Flor. Virg. *White Walnut with a ſmaller fruit, and a ſmooth bark.*
6. Juglans (*Ovata*) foliolis lanceolatis ſerratis glabris ſubæqualibus. *Walnut with ſmooth, ſpear-ſhaped, ſawed lobes, which are equal.* Juglans alba fructu ovato compreſſo, nucleo dulce, cortice ſquamoſo. Clayt. Flor. Virg. *White Walnut with an oval compreſſed fruit, a ſweet kernel, and a ſcaly bark, commonly called Shag-bark in America.*

There are ſeveral varieties of the common Walnut, which are diſtinguiſhed by the following titles: the large Walnut, the thin ſhelled Walnut, the French Walnut, the late ripe Walnut, and the double Walnut; but theſe do all of them vary when raiſed by the ſeed, ſo that the nuts from the ſame tree will produce plants whoſe fruit will differ; therefore there can be no dependence upon the trees which are raiſed from nuts, till they have produced fruit; ſo that thoſe perſons who plant the trees for their fruit, ſhould make choice of them in the nurſeries when they have their fruit upon them, otherwiſe they may be deceived, by having ſuch as they would not chuſe.

The ſecond ſort is commonly called Black Virginia Walnut; this grows to a large ſize in North America. The leaves of this ſort are compoſed of five or ſix pair of ſpear-ſhaped lobes, which end in acute points, and are ſawed on their edges; the lower pair of lobes are the leaſt, the other gradually increaſe in their ſize to the top, where the pair at the top, and the ſingle lobe which terminates the leaf, are ſmaller; theſe leaves, when bruiſed, emit a ſtrong aromatic flavour, as do alſo the outer cover of the nuts, which are rough, and rounder than thoſe of the common Walnut. The ſhell of the nut is very hard and thick, and the kernel ſmall, but very ſweet.

The third ſort grows naturally in North America, where the trees grow to a large ſize. The leaves of this ſort are compoſed of ſeven or eight pair of long heart-ſhaped lobes, broad at their baſe, where they are divided into two round ears, but terminate in acute points; they are rougher, and of a deeper green than thoſe of the ſecond ſort, and have nothing of the aromatic ſcent which they have. The fruit is very long. The ſhell is deeply furrowed, and is very hard. The kernel is ſmall, but well flavoured.

The fourth ſort is very common in moſt parts of North America, where it is called Hickery Nut. The leaves of this ſort are compoſed of two or three pair of oblong lobes, terminated by an odd one; theſe are of a light green, and ſawed on their edges; the lower pair of lobes are the ſmalleſt, and the upper the largeſt. The fruit is ſhaped like the common Walnut; but the ſhell is not furrowed, and is of a light colour.

The fifth ſort is not ſo large as the fourth. The leaves are compoſed of two pair of lobes, terminated by an odd one; theſe are narrow at their baſe, but broad and rounded at their ends; they are ſawed on their edges, and are of a light green. The nuts are ſmall, have a ſmooth ſhell, and are very hard and white.

The ſixth ſort grows naturally in North America, where it riſes to a middling ſtature. The leaves of this ſort are compoſed of three pair of ſmooth ſpear-ſhaped lobes, of a dark green colour, ſawed on their edges, and ending in acute points. The fruit is oval, the ſhell white, hard, and ſmooth; the kernel ſmall, but very ſweet. The young ſhoots of the tree are covered with a very ſmooth browniſh bark, but the ſtems and older branches have a rough ſcaly bark, from whence it had the appellation of Shagbark, in America.

The common Walnut is propagated in many parts of England for the fruit, and formerly the trees were propagated for their wood, which was in very great eſteem, till the quantity of Mahogany, and other uſeful woods which have been of late years imported into England, have almoſt baniſhed the uſe of Walnut.

Theſe trees are propagated by planting their nuts, which, as was before obſerved, ſeldom produce the ſame ſort of fruit as are ſown; ſo that the only way to have the deſired ſort, is to ſow the nuts of the beſt kinds; and if this is done in a nurſery, the trees ſhould be tranſplanted out when they have had three or four years growth, to the place where they are deſigned to remain; for theſe trees do not bear tranſplanting when they are of a large ſize, therefore there may be a good number of the trees planted, which need not be put at more than ſix feet apart, which will be diſtance enough for them to grow till they produce fruit; when thoſe whoſe fruit are of the deſired kind may remain, and the others cut up, to allow them room to grow; by this method a ſufficient number of the trees may be generally found among them to remain, which will thrive and flouriſh greatly when they have room; but as many people do not care to wait ſo long for the fruit, ſo the next beſt method is to make choice of ſome young trees in the nurſeries, when they have their fruit upon them; but though theſe trees will grow and bear fruit, yet they will never be ſo large or ſo long lived, as thoſe which are planted young.

All the ſorts of Walnuts which are propagated for timber, ſhould be ſown in the places where they are to remain; for the roots of theſe trees always incline downward, which being ſtopped or broken, prevent their aſpiring upward, ſo that they afterwards divaricate into branches, and become low ſpreading trees; but ſuch as are propagated for fruit, are greatly mended by tranſplanting; for hereby they are rendered more fruitful, and their fruit are generally larger and fairer; it being a common obſervation, that downright roots greatly encourage the luxuriant growth of timber in all ſorts of trees; but ſuch trees as have their roots ſpreading near the ſurface of the ground, are always the moſt fruitful and beſt flavoured.

The nuts ſhould be preſerved in their outer covers in dry ſand until February, when they ſhould be planted in lines, at the diſtance you intend them to remain; but in the rows they may be placed pretty cloſe, for fear the nuts ſhould miſcarry; and the young trees, where they are too thick, may be removed, after they have grown two or three years, leaving the remainder at the diſtance they are to ſtand.

In tranſplanting theſe trees, you ſhould obſerve never to prune either their roots or large branches, both which are very injurious to them; nor ſhould you be too buſy in lopping or pruning the branches of theſe trees when grown to a large ſize, for it often cauſes them to decay; but when there is a neceſſity for cutting any of their branches off, it ſhould be done early in September (for at that ſeaſon the trees are not ſo ſubject to bleed) that the wound may heal over before the cold increaſes; the branches ſhould always be cut off quite cloſe to the trunk, otherwiſe the ſtump which is left will decay, and rot the body of the tree.

The beſt ſeaſon for tranſplanting theſe trees is as ſoon as the leaves begin to decay, at which time if they are carefully taken up, and their branches preſerved entire, there will be little danger of their ſucceeding, although they are eight or ten years old, as I have ſeveral times experienced; though, as was before obſerved, theſe trees will not grow ſo large, or continue ſo long, as thoſe which are removed young.

This tree delights in a firm, rich, loamy ſoil, or ſuch as is inclinable to chalk or marl; and will thrive very well in ſtony ground, and on chalky hills, as may be ſeen by thoſe large plantations near Leatherhead, Godſtone, and Carſhalton in Surry, where are great numbers of theſe trees planted upon the downs, which annually produce large quantities of fruit, to the great advantage of their owners; one of which I have been told, farms the fruit of his trees, to thoſe who ſupply the markets, for 30 l. per annum.

The diſtance theſe trees ſhould be placed, ought not to be leſs than forty feet, eſpecially if regard be had to their fruit; though when they are only deſigned for timber, if they ſtand much nearer, it promotes their upright growth. The black Virginia Walnut is much more inclinable to grow upright than the common ſort, and the wood being generally of a more beautiful grain, renders it preferable to that, and better worth cultivating. I have ſeen ſome of this wood which hath been beautifully veined with black and white, which, when poliſhed, has appeared at a diſtance, like veined marble. This wood is greatly eſteemed by the cabinet-makers for inlaying, as alſo for bedſteads, ſtools, tables, and cabinets; and is one of the moſt durable woods for thoſe purpoſes of Engliſh growth, being leſs liable to be infected with inſects than moſt other kinds (which may proceed from its extraordinary bitterneſs;) but it is not proper for buildings of ſtrength, it being of a brittle nature, and exceeding ſubject to break very ſhort, though it commonly gives notice thereof, by its cracking ſome time before it breaks.

The general opinion is, that the beating of this fruit improves the trees, which I do not believe, ſince in the doing of this, the younger branches are generally broken and deſtroyed; but as it would be exceeding troubleſome to gather it by hand, ſo in beating it off, great care ſhould be taken that it be not done with violence, for the reaſon before aſſigned. In order to preſerve the fruit, it ſhould remain upon the trees till it is thorough ripe, when it ſhould be beaten down, and laid in heaps for two or three days; after which they ſhould be ſpread abroad, when, in a little time, their huſks will eaſily part from the ſhells; then you muſt dry them well in the ſun, and lay them up in a dry place, where mice or other vermin cannot come to them, in which place they will remain good for four or five months; but there are ſome perſons who put their Walnuts into an oven gently heated, where they let them remain four or five hours to dry, and then put them up in oil jars, or any other cloſe veſſel, mixing them with dry ſand, by which method they will keep good ſix months. The putting of them in the oven is to dry the germ, and prevent their ſprouting; but if the oven be too hot it will cauſe them to ſhrink, therefore great care muſt be had to that.

All the other ſorts are propagated in the ſame way, but as few of the ſorts produce fruit in England, ſo their nuts muſt be procured from North America; which ſhould be gathered when fully ripe, and put up in dry ſand, to preſerve them in their paſſage to England: when they arrive here, the ſooner they are planted the greater chance there will be of their ſucceeding;

ceeding; when the plants come up, they ſhould be kept clean from weeds; and if they ſhoot late in the autumn, and their tops are full of ſap, they ſhould be covered with mats, or ſome other light covering, to prevent the early froſts from pinching their tender ſhoots, which often cauſes them to die down a conſiderable length before the ſpring; but if they are ſcreened from theſe early froſts, the ſhoots will become firmer and better able to reſiſt the cold. Some of theſe ſorts are tender while young, ſo require a little care for the two firſt winters, but afterward will be hardy enough to reſiſt the greateſt cold of this country.

The black Virginia Walnut is full as hardy as the common ſort: there are ſome large trees of this kind in the Chelſea garden, which have produced great quantities of fruit upward of forty years; the nuts have generally ripened ſo well there as to grow, but their kernels are ſmall, ſo are of little value.

The trees all require the ſame culture as the common Walnut, but they grow beſt in a ſoft loamy ſoil not too dry, and where there is a depth of ſoil for their roots to run down. The Hickery, when young, is very tough and pliable, ſo the ſticks of it are much eſteemed; but the wood when grown large is very brittle, ſo not of any great uſe. The black Virginia Walnut is the moſt valuable wood of all the ſorts; ſome of the trees are beautifully veined, and will take a good poliſh, but others have very little beauty, which is the caſe of many other ſorts of wood.

JUJUBE. See ZIZIPHUS.

JULIANS, or ROCKETS. See HESPERIS.

JULY FLOWER. See DIANTHUS.

JUNCUS. Tourn. Inſt. R. H. 246. tab. 127. Lin. Gen. Plant. 396. Ruſh; in French, *Jonc.*

The CHARACTERS are,

It hath a chaff opening with two valves, an empalement with ſix oblong pointed little leaves which are permanent; the flower hath no petals, but the coloured empalement is by ſome taken for petals. It hath ſix ſhort hairy ſtamina, terminated by oblong erect ſummits, and a three-cornered pointed germen, with a ſhort ſlender ſtyle, crowned by three long, hairy, ſlender ſtigmas, which are reflexed. The germen afterward becomes a cloſe three-cornered capſule with one cell, opening with three valves, incloſing roundiſh ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's ſixth claſs, intitled Hexandria Monogynia, which contains the plants whoſe flowers have ſix ſtamina and one ſtyle.

The SPECIES are,

1. JUNCUS (*Acutus*) culmo ſubnudo tereti mucronato, paniculâ terminali, involucro diphyllo ſpinoſo. Lin. Sp. Plant. 325. *Ruſh with a naked, taper, pointed ſtalk, terminated by a panicle, and a prickly two-leaved involucrum.* Juncus acutus, capitulis ſorghi. C. B. P. 11. *Prickly large Sea Ruſh.*

2. JUNCUS (*Filiformis*) culmo nudo, apice membranaceo incurvo, paniculâ laterali. Lin. Sp. Plant. 326. *Ruſh with a naked ſtalk, an incurved membranacous apex, and a lateral panicle.* Juncus acutus, panicula ſparſa. C. B. P. *Common hard Ruſh.*

3. JUNCUS (*Effuſus*) culmo nudo ſtricto, paniculâ laterali. Flor. Leyd. 44. *Ruſh with a naked cloſe ſtalk, and a lateral panicle.* Juncus lævis, paniculâ ſparsâ, major. C. B. P. *Larger common ſoft Ruſh, with a ſpreading panicle.*

4. JUNCUS (*Conglomeratis*) culmo nudo ſtricto, capitulo laterali. Prod. Leyd. 44. *Ruſh with a cloſe naked ſtalk and lateral heads.* Juncus lævis, paniculâ non ſparsâ. C. B. P. *Soft Ruſh with a more compact panicle.*

There are many other ſpecies of this genus, ſome of which grow naturally in England, and are very troubleſome weeds in many places, ſo are not worthy of being enumerated here; and thoſe which are here mentioned, is only to point out a method of deſtroying them.

The firſt and ſecond ſorts grow on the ſea-ſhores, where they are frequently watered by the ſalt water. Theſe two ſorts are planted with great care on the banks of the ſea in Holland, in order to prevent the water from waſhing away the earth; which being very looſe, would be in danger of removing every tide, if it were not for the roots of theſe Ruſhes, which faſten themſelves very deep in the ground, and mat themſelves near the ſurface, ſo as to hold the earth cloſely together. Therefore, whenever the roots of theſe Ruſhes are deſtroyed, the inhabitants immediately repair them to prevent farther damage. In the ſummer time, when the Ruſhes are fully grown, the inhabitants cut them, and tie them up into bundles, which are dried, and afterward carried into the larger towns and cities, where they are wrought into baſkets, and ſeveral other uſeful things, which are frequently ſent into England. Theſe ſorts do not grow ſo ſtrong in England, as they do on the Maeſe, and ſome other places in Holland, where I have ſeen them upward of four feet high.

The third and fourth ſorts grow on moiſt, ſtrong, uncultivated lands in moſt parts of England, and conſume the herbage where they are ſuffered to remain. The beſt method of deſtroying theſe Ruſhes is, to fork them up clean by the roots in July, and after having let them lie a fortnight or three weeks to dry, to lay them in heaps, and burn them gently; and the aſhes which theſe afford, will be good manure for the land; but in order to prevent their growing again, and to make the paſture good, the land ſhould be drained, otherwiſe there will be no deſtroying theſe Ruſhes entirely; but after it is well drained, if the roots are annually drawn up, and the ground kept duly rolled, they may be ſubdued.

JUNIPERUS. Tourn. Inſt. R. H. 588. tab. 361. Lin. Gen. Plant. 1005. Juniper; in French, *Genévrier.*

The CHARACTERS are,

It hath male and female flowers in different plants, and ſometimes at ſeparate diſtances on the ſame plant. The male flowers grow on a conical katkin; the flowers are placed by threes, two of them faſtened along the common tail oppoſite, terminated by a ſingle one; the ſcales are broad, ſhort, lying over each other, and fixed to the column by a very ſhort foot-ſtalk. The flower has no petal, but three ſtamina in the male flower which are joined in one body below, having three diſtinct ſummits, adhering to the ſcales of the lateral flowers. The female flowers have a ſmall three-pointed empalement ſitting upon the germen, which is permanent; they have three ſtiff, acute, permanent petals; the germen ſitting below the empalement, ſupports three ſingle ſtyles, crowned by ſtigmas. The germen afterward becomes a roundiſh berry, incloſing three ſtony ſeeds, which are oblong and angular on one ſide, but convex on the other.

This genus of plants is ranged in the twelfth ſection of Linnæus's twenty-ſecond claſs, intitled Diœcia Monodelphia, which includes thoſe plants which have male and female flowers in different plants, whoſe ſtamina are joined in one body.

The SPECIES are,

1. JUNIPERUS (*Communis*) foliis ternis patentibus mucronatis bacca longioribus. Lin. Sp. Plant. 1040. *Juniper with ſpreading ſharp-pointed leaves placed by threes.* Juniperis vulgaris fruticoſa. C. B. P. 488. *The common Engliſh Juniper.*

2. JUNIPERIS (*Suecia*) foliis ternis patentibus, acutioribus, ramis erectioribus, bacca longioribus. *Juniper with longer and more acute-pointed leaves placed by threes, erect branches, and longer berries.* Juniperis vulgaris arbor. C. B. P. 488. *The Tree, or Swediſh Juniper.*

3. JUNIPERUS (*Virginiana*) foliis ternis omnibus patentibus. *Juniper with leaves placed by threes, which are all of them ſpreading.* Juniperus Virginiana. H. L. Folio ubique juniperino. Boerh. Ind. *Cedar of Virginia, or red Cedar.*

4. JUNIPERUS (*Caroliniana*) foliis ternis baſi adnatis, junioribus imbricatis, ſenioribus patulis. Hort. Cliff. 464. *Juniper with leaves placed by threes adhering at their baſe, the young ones lying over each other, and the old ones ſpreading.* Juniperus Virginiana, foliis inferioribus juniperinis, ſuperioribus ſabinam, vel cypreſſum referentibus. Boerh. Ind. *Carolina Cedar.*

5. Juniperus (*Bermudiana*) foliis inferioribus ternis, ſuperioribus quadrifariàm imbricatis. *Juniper with ſpreading under leaves placed by threes, and the upper by fours, which lie cloſe over each other.* Juniperis Bermudiana. H. L. *Cedar of Bermudas.*

6. Juniperis (*Thurifera*) foliis quadrifariàm imbricatis acutis. Lin. Sp. 1471. *Juniper with awl-ſhaped acute leaves placed by fours, lying over each other.* Juniperus major baccâ cæruleâ. C. B. P. *Greater Juniper with blue berries.*

7. Juniperus (*Phœnicia*) foliis ternis obliteratis imbricatis obtuſis. Lin. Sp. 1471. *Juniper with leaves placed by threes, which are obliterate, obtuſe, and lying over each other.* Cedrus folio cupreſſi major, fructu flaveſcente. C. B. P. *Greater Cedar with a Cypreſs leaf and yellowiſh fruit.*

8. Juniperus (*Lycia*) foliis ternis undique imbricatis ovatis obtuſis. Flor. Leyd. 90. *Juniper with oval blunt leaves, which every where lie over each other.* Cedrus folio cupreſſi media, majoribus baccis. C. B. P. 488. *Middle Cedar, with a Cypreſs leaf and larger berries.*

9. Juniperus (*Barbadenſis*) foliis omnibus quadrifariàm imbricatis junioribus ovatis ſenioribus acutis. Prod. Leyd. 90. *Juniper with all the leaves placed by fours, lying over each other, the young being oval, the older acute.* Juniperus maxima cupreſſi folio minimo, cortice exteriore in tenues philyras ſpiralis ductili. Sloan. Cat. Jam. 128. *Greateſt Juniper with the leaſt Cypreſs leaf, and the outer bark ſplitting off in thin ductile pieces, commonly called Jamaica Berry-bearing Cedar.*

10. Juniperus (*Sabina*) foliis oppoſitis erectis decurrentibus, ramis patulis. *Juniper with oppoſite, erect, running leaves, and ſpreading branches.* Sabina folio tamariſci. C. B. P. 487. *Savin with a Tamariſk-leaf, or common Savin.*

11. Juniperus (*Luſitanica*) foliis oppoſitis patulis decurrentibus, ramis erectioribus. *Juniper with oppoſite ſpreading leaves, which run over each other, and more erect branches.* Sabina folio cupreſſi. C. B. P. 487. *Savin with a Cypreſs leaf, commonly called Berry-bearing Savin.*

12. Juniperus (*Oxycedrus*) foliis undique imbricatis obtuſis, ramis teretibus. *Juniper with obtuſe leaves every-where lying over each other, and taper branches.* Juniperus major, baccâ rufeſcente. C. B. P. 489. *Greater Juniper with a browniſh berry.*

13. Juniperus (*Hiſpanica*) foliis quadrifariàm imbricatis acutis. Prod. Leyd. 90. *Juniper with acute leaves lying over each other, placed four ways.* Cedrus Hiſpanica procerior, fructu maximo nigro. Tourn. Inſt. 588. *Taller Spaniſh Cedar, with a very large black fruit.*

The firſt ſort grows naturally upon chalky lands in many parts of England. This is a low ſhrub, ſeldom riſing more than three feet high, ſending out many ſpreading branches, which incline on every ſide, covered with a brown bark, and garniſhed with narrow awl-ſhaped leaves ending in acute points, which are placed by threes round the branches, pointing outward; theſe are of a grayiſh colour, and continue through the year; the male flowers ſometimes are ſituated on the ſame plant with the female, but at diſtances, at other times they are upon diſtinct plants: the female flowers are ſucceeded by roundiſh berries, which are firſt green, but when ripe, are of a dark purple colour. The berries ripen in the autumn.

The wood, the berries, and the gum, are uſed in medicine; the gum is titled Sandaracha.

The ſecond ſort is known in the gardens by the title of Swediſh Juniper: this is by many ſuppoſed to be only a variety of the firſt, but is undoubtedly a diſtinct ſpecies, for I have many years raiſed both ſorts from the ſeeds, and have never found them alter. This ſort riſes to the height of ten or twelve feet, the branches grow more erect, the leaves are narrower, and end in more acute points: they are placed farther aſunder on the branches, and the berries are longer. It grows naturally in Sweden, Denmark, and Norway.

The third ſort grows naturally in moſt parts of North America, where it is called red Cedar, to diſtinguiſh it from a ſort of Cypreſs, which is called white Cedar there. Of this there are two, if not three varieties, beſides the ſpecies here enumerated; one of which has leaves in every part, like thoſe of the Savin, and upon being rubbed, emit a very ſtrong ungrateful odour: this is commonly diſtinguiſhed in America, by the title of Savin-tree. There is another with leaves very like thoſe of Cypreſs, but as theſe generally ariſe from the ſame ſeeds when they are ſent from America, ſo they may be ſuppoſed to be only ſeminal variations.

The lower leaves of the fourth ſort are like thoſe of the Swediſh Juniper, but the upper leaves are like thoſe of the Cypreſs; and this difference is conſtant, if the ſeeds are carefully gathered from the ſame tree; but as moſt of thoſe people who ſend over theſe ſeeds, are not very careful to diſtinguiſh the difference, ſo it often happens that the ſeeds of two or three ſorts are mixed together, which has given occaſion to people to imagine them but one ſpecies; but all the leaves of the third are like thoſe of the Juniper, ſo the gardeners call this the red Virginia Cedar; and the fourth they call Carolina Cedar, though all the ſorts grow naturally in Virginia.

The fifth ſort is the Bermudas Cedar, whoſe wood has a very ſtrong odour, and was formerly in great eſteem for wainſcotting of rooms, and alſo for furniture; but the odour being too powerful for many perſons, has rendered it leſs valuable, and at preſent there is not much of it imported into England. Theſe plants, while young, have acute-pointed leaves, which ſpread open, and are placed by threes round the branches; but as the trees advance, ſo their leaves alter, and the branches are four-cornered; the leaves are very ſhort, and placed by fours round the branches, lying over each other like the ſcales of fiſh; the berries are produced toward the end of the branches; theſe are of a dark red colour, inclining to purple. As there are few of theſe trees of any great ſize in England, ſo I have not had an opportunity of examining their flowers, therefore do not know if they have male and female flowers on the ſame plant, or if they are on different plants; for although I have received very fine ſpecimens from Bermudas, yet they are all with fruit on them almoſt fully grown, and not one with male flowers; and as theſe trees are commonly deſtroyed in England whenever there happens a ſevere winter, where they are not ſheltered, ſo we have little hopes of ſeeing them in flower here.

The ſixth ſort grows naturally in Iſtria, from whence I received the berries, which have ſucceeded with me in the Chelſea garden. This hath ſpreading branches, growing thinly, which are garniſhed with acute-pointed leaves, placed by fours round the branches; they are of a deep green, and not very cloſe to each other, but grow horizontally, pointing outward; the berries are much larger than thoſe of the common Juniper, and are blue when ripe.

The ſeventh ſort grows naturally in Portugal, from whence I have frequently received the berries. This ſort grows with its branches in a pyramidical form; the lower ones are garniſhed with ſhort, acute-pointed, grayiſh leaves, placed by threes round the branches, pointing outward; but thoſe on the upper branches are of a dark green, lying over each other like the ſcales of fiſh, but end in acute points. The male flowers are produced at the extremity of the branches; they are ſituated in a looſe, ſcaly, conical katkin, ſtanding upon a ſhort foot-ſtalk erect; the fruit is produced ſometimes upon the ſame tree, at diſtances from the flowers, and at other times they are upon ſeparate trees; the berries of this are of a pale yellow when ripe, and about the ſize of thoſe of the common Juniper.

The eighth ſort grows naturally in Spain and Italy, from both which countries I have received it. The branches of this ſort grow erect, and are covered with a reddiſh brown bark; the leaves are ſmall, obtuſe, and lie over each other like the ſcales of fiſh; the male flowers grow at the extremity of the branches in a conical katkin, and the fruit grows ſingle from the ſide of the branches below the katkins, on the ſame branch; the berries are large, oval, and, when ripe, are brown.

The ninth ſort grows naturally in Jamaica, and alſo in the other iſlands of the Weſt-Indies, where it riſes to be one of the largeſt timber trees in thoſe countries; the wood is frequently fetched from thence by the inhabitants of North America, for building of ſhips. This ſort is generally confounded with the Bermudas Cedar, and taken for the ſame, but the ſpecimens of it which were ſent me by the late Dr. Houſtoun, prove them to be different trees; for the branches of this ſpread very wide, the leaves are extremely ſmall, and are every where lying imbricatim over each other; the bark is rugged, and ſplits off in ſtrings, and is of a very dark colour; the berries are ſmaller than thoſe of the Bermudas Cedar, and are of a light brown colour when ripe: this ſort is male and female in different trees.

The tenth ſort is the common Savin; this grows naturally in Italy, Spain, and the Levant, upon the mountains where it is cold. It ſends out its branches horizontally, ſo ſeldom riſes more than three or four feet high, but ſpreads to a conſiderable diſtance every way; the branches are garniſhed with very ſhort acute-pointed leaves placed oppoſite, which run over each other along the branches, whoſe ends point upward. This ſort very rarely produces either flower or ſeed in the gardens; I have frequently examined old plants which have been ſtanding more than fifty years, and have not more than three times found any male flowers upon them, and but once have ſeen any berries, which were upon a ſeparate tree from the flowers; theſe berries were ſmaller than thoſe of the common Juniper, but of the ſame colour, and were a little compreſſed; the whole plant has a very rank ſtrong odour when touched. The leaves of this ſhrub are much uſed by the farriers for horſes when they have worms; and Mr. Ray commends the juice of it mixed with milk, and ſweetened with ſugar, as an excellent medicine for children who are troubled with worms. The leaves beaten into a cataplaſm with hog's-lard, will cure children's ſcabby heads.

The eleventh ſort has, by many, been ſuppoſed to be only an accidental variety of the former, but there is a manifeſt difference between them; for the branches of this grow more erect than thoſe of the eleventh ſort, the leaves are ſhorter, and end in acute points which ſpread outward. This ſort will riſe to the height of ſeven or eight feet, and produces great quantities of berries. I have propagated this ſort from ſeeds, but have never found it vary. It has been diſtinguiſhed by moſt of the old botaniſts, by the title of Berry-bearing Savin. It grows naturally on the Alps, from whence I have received the berries.

The twelfth ſort grows naturally in Spain, Portugal, and the ſouth of France, where it riſes ten or twelve feet high, ſending out branches the whole length of the ſtem, which are garniſhed with ſmall obtuſe leaves, lying over each other like the ſcales of fiſh; the branches are ſmall and taper, having no angles or corners, as moſt of the others have; the male flowers are ſituated at the end of the branches in conical ſcaly katkins, and the berries grow below from the ſide of the ſame branches. Theſe are larger than thoſe of the common Juniper, and when ripe are brown.

The thirteenth ſort grows naturally in Spain and Portugal, where it riſes from twenty-five to thirty feet high, ſending out many branches which form a ſort of pyramid; the branches are garniſhed with acute-pointed leaves, which lie over each other four ways, ſo as to make the branches four-cornered; the berries of this ſort are very large, and black when ripe.

Theſe plants are all propagated by ſowing their ſeeds, the beſt ſeaſon for which is as ſoon as they are ripe, if they can then be procured; for when they are kept until ſpring before they are ſown, they will not come up until the ſecond year. The ground in which the ſeeds of the hardy ſorts are ſown, ſhould be freſh and light, but it ſhould not be dunged: it ſhould be well dug and levelled very even; then ſow your ſeeds thereon pretty thick, and ſift ſome earth over them about half an inch thick; this bed will require no farther care than only to keep it clear from weeds, and toward the middle or latter end of April, you will find ſome of your plants appear above ground, though, perhaps, the greateſt part of them may lie till the ſpring following before they come up; therefore you ſhould carefully clear the beds from weeds, and in very dry weather refreſh them with ſome water, which will greatly promote the growth of thoſe plants which are up, and alſo cauſe the other ſeeds to vegetate; but if the bed in which theſe ſeeds are ſown is much expoſed to the ſun, it ſhould be ſhaded with mats in the day; for when the plants come firſt up, they will not bear too much heat. In this bed they ſhould remain till the ſecond autumn, when you muſt prepare ſome beds to tranſplant them into, which ſhould alſo be of light, freſh, undunged ſoil; and having well dug and cleanſed the ground from all noxious weeds and roots, you ſhould make it level; and then in the beginning of October, which is the proper ſeaſon for removing theſe plants, you ſhould raiſe up the young plants with a trowel, preſerving as much earth as poſſible to their roots, and plant them into beds about five or ſix inches aſunder each way, giving them ſome water to ſettle the earth to their roots; and if it ſhould prove very dry weather, you may lay a little mulch upon the ſurface of the ground round their roots, which will be of great ſervice to the plants. But as many of the ſeeds will be yet left in the ground where they are ſown, ſo the beds ſhould not be diſturbed too much in taking up the plants; for I have known a bed ſown with theſe berries, which has ſupplied plants for three years drawing, ſome of the berries having lain ſo long in the ground before they ſprouted; therefore the ſurface of the beds ſhould be kept level, and conſtantly clean from weeds.

The plants may remain two years in theſe beds, obſerving to keep them clear from weeds; in the ſpring you ſhould ſtir the ground gently between them, that their roots may with greater eaſe ſtrike into it; after which time they ſhould be tranſplanted, either into a nurſery, at the diſtance of three feet row from row, and eighteen inches aſunder in the rows, or into the places where they are to remain for good. The beſt ſeaſon to tranſplant them (as I before obſerved) is in the beginning of October, when you ſhould take them up carefully, to preſerve a ball of earth to their roots; and when planted, their roots ſhould be mulched; all which, if carefully attended to, as alſo obſerving to refreſh them with water in very dry weather until they have taken new root, will preſerve them from the danger of not growing; and they being extreme hardy in reſpect to cold, will defy the ſevereſt of our winters to injure them, provided they are not planted in a moiſt or rich ſoil.

In order to have theſe trees aſpire in height, their under branches ſhould be taken off, eſpecially where they are inclined to grow ſtrong, but they muſt not be kept too cloſely pruned, which would retard their growth; for all theſe Evergreen trees do more or leſs abound with a reſinous juice, which in hot weather is very apt to flow out from ſuch places as are wounded; ſo that it will not be adviſeable to take off too many branches at once, which would make ſo many wounds, from which their ſap in hot weather would flow in ſuch plenty, as to render the trees weak and unhealthy.

The two ſorts of Virginian Cedars grow to a much greater height than the former, and in their native country afford excellent timber for many uſes; but with us there are very few which are above twenty-five or thirty feet high, though there is no doubt of their growing larger; for they thrive very faſt after the three firſt years, and reſiſt the ſharpeſt froſt of our climate exceeding well, and are very apt to grow ſtrait and regular, provided they are not ſuffered to ſhoot out too much at bottom.

Theſe plants are alſo propagated by ſeeds, which muſt be procured from Virginia or Carolina (for they rarely produce ripe ſeeds in England) and ſown as was directed for the other Junipers; but as this ſeed cannot be procured in England till ſpring, ſo when ſown at that ſeaſon, it remains in the ground until the ſucceeding ſpring before the plants appear; therefore you muſt obſerve to keep the beds clear from weeds, and not ſuffer the ſeeds to be diſturbed, which is often the fault of ſome impatient people, who think, becauſe the plants do not riſe the firſt year, that they will never come up, and ſo dig up the ground again, whereby their ſeeds are buried; but if they are let remain, they ſeldom fail to grow, though ſometimes it is two years after ſowing before they come up. When the plants come up they muſt be carefully weeded, and in dry weather ſhould be refreſhed with water, which will greatly forward their growth; and the autumn following they ſhould have a little rotten tan laid between them, to keep out the froſt. In this bed the plants may remain till they have had two years growth, then they ſhould be tranſplanted into other beds, as was directed before for the other ſorts, obſerving to preſerve a ball of earth to their roots; and after they are planted, if the ſeaſon proves dry, they muſt be carefully watered, and the ſurface of the ground covered with mulch, to prevent the ſun and wind from entering the earth to dry their fibres; but they ſhould not be too much watered, which often proves injurious to theſe trees, by rotting their tender fibres ſoon after they are emitted, whereby the plants have been often deſtroyed.

In theſe beds they may remain two years, obſerving to keep them clear from weeds; and in winter you ſhould lay a little freſh mulch upon the ſurface of the ground round their roots, which will prevent the froſt from penetrating to them, and effectually preſerve them; for while the plants are ſo young, they are liable to be injured by hard froſts, when too much expoſed thereto; but when they have attained a greater ſtrength, they will reſiſt the ſevereſt of our cold.

After two years, they ſhould either be removed into a nurſery (as was directed for the common Juniper) or tranſplanted where they are deſigned to remain, obſerving always to take them up carefully, otherwiſe they are ſubject to fail upon tranſplanting; as alſo to mulch the ground, and water them as was before directed, until they have taken root; after which they will require no farther care, than only to keep the ground clear about their roots, and to prune up their ſide branches to make them aſpire in height.

The ſoil in which you plant theſe trees ſhould be freſh and light, but muſt not be dunged, eſpecially at the time when they are planted; for dung is very hurtful to them, if it be not quite rotted to mould; therefore the mulch which is laid upon the ſurface of the ground ſhould not be dung, but rather ſome old tanners bark or ſea-coal aſhes, which will prevent the froſt from penetrating deep in the ground.

Theſe trees being thus managed, will in a few years riſe to a conſiderable ſtature, and by the variety of their evergreen leaves and manner of growth, will greatly add to the beauty of all plantations, if rightly diſpoſed, which indeed is what we ſeldom obſerve in any of the Engliſh gardens or wilderneſſes; for there are few people who conſider the different growths of the ſeveral trees with which they compoſe ſuch plantations, ſo as to place the talleſt growing trees the backwardeſt from ſight, and the next degree to ſucceed them, and ſo gradually diminiſhing till we come to the common Juniper, and others of the ſame growth, whereby all the trees will be ſeen, and the gradual declivity of their tops will appear like a verdant ſlope, and be much more agreeable to the ſight, as alſo more advantageous to the growth of the trees, than to place ſhrubs of humble growth near ſuch plants as will grow to the firſt magnitude, whereby the ſhrub is hid from ſight, and will be over-ſhadowed and deſtroyed; nor can the diſtance which each tree requires, be ſo juſtly proportioned any other way; for in this diſtribution, the largeſt trees being ſeparated by themſelves, may be placed at a due diſtance; and then thoſe of a middling growth ſucceeding, may be accordingly allowed ſufficient room; and the ſmaller, which are next the ſight, being placed much cloſer, will hide the naked ſtems of the larger trees, and have an agreeable effect to the ſight.

The timber of theſe trees is of excellent uſe in America, for building of veſſels, wainſcotting houſes, and for making many ſorts of utenſils, it abounding with a bitter reſin, which prevents its being deſtroyed by vermin, but it is very brittle, therefore not ſo proper for ſtubborn uſes; but however, by increaſing the number of our timber trees, we ſhall find many advantages, beſides the pleaſure their variety affords; for we may hereby have trees of very different kinds, which are adapted to grow in various ſoils and ſituations, whereby we ſhall never want proper trees for all the different ſorts of ſoils in England, if proper care be taken in their choice; which would be a great improvement to many parts of this kingdom, which now lie unplanted, becauſe the owner, perhaps, find that neither Oaks nor Elms will thrive there, and conſequently concludes, that no other ſort of tree will, which is a great miſtake; for if we conſider how different the ſtructure of trees are (being deſigned by the wiſe Author and contriver of all things, to grow on different ſoils and ſituations) and only obſerve what ſorts are adapted for growing on dry barren mountains, and what are deſigned for the lower and richer valleys, we need never be at a loſs for proper trees for all ſorts of ground.

The Bermudas Cedar being a native of that iſland, and alſo of the Bahama Iſlands, is much tenderer than either of the former ſorts, except that of Jamaica, ſo is not likely to thrive well in this country; for although many of theſe plants have lived ſeveral years in the open air in England, yet whenever a ſevere winter happens, it either kills them, or ſo much defaces them, that they do not recover their verdure in a year or two after.

Theſe plants are propagated by ſeeds in the ſame manner as the former, with only this difference, that theſe ſhould be ſown in pots or tubs of earth, that they may be removed into ſhelter in the winter time, otherwiſe the young plants are often hurt by hard froſts; but they will require no more care than only to be placed under a common hot-bed frame, where the glaſſes may be conſtantly kept off in mild weather, when they cannot have too much free air, and only covered in hard froſts. Theſe ſeeds conſtantly remain in the ground until the ſecond year before they come up, therefore the earth in the pots ſhould not be diſturbed; and in the ſummer time they ſhould be placed in the ſhade, to prevent the earth from drying too faſt; and in very dry weather they ſhould be often watered, but do not give too much water to them at once, which would rot the ſeeds.

The ſpring following, when the young plants come up, they muſt be carefully cleared from weeds, and in dry weather refreſhed with water; but ſhould ſtand, during the ſummer ſeaſon, in a place defended from ſtrong winds; and in winter muſt be placed under frames, where they may be covered in hard froſty weather, but muſt have open air when the weather is mild. In April following you ſhould tranſplant them each into a ſingle halfpenny pot filled with freſh light earth, being careful to raiſe them up with a ball of earth to their roots; and when they are planted, you ſhould water them, to ſettle the earth to their roots; then place the pots in a warm ſituation, where they may be defended from ſun and wind: but if you will beſtow a moderate hot bed to plunge the pots in, it will greatly promote their taking new root; however, you muſt carefully defend them from the great heat of the ſun, which is injurious to them when freſh removed; but when they have taken root, you may expoſe them by degrees to the open air. If you ſuffer the pots to remain plunged all the ſummer, it will preſerve the earth therein from drying ſo faſt as it would do, if they were ſet upon the ground.

In October you ſhould again remove theſe plants into ſhelter, or elſe plunge their pots into the ground under a warm hedge, where they may be protected from the cold north and eaſt winds; and in the ſpring following you muſt ſhift the plants into pots a ſize larger, taking away ſome of the earth from the outſide of the ball, and adding ſome freſh, which will promote their growth; and ſo continue to manage them as was before directed, until you plant them out in the places where they are deſigned to remain; which ſhould not be done till they are four or five years old, by which time they will be ſtrong enough to bear the cold of our common winters.

The reaſon for my directing theſe plants to be preſerved in pots until they are planted out for good is, becauſe they are difficult to tranſplant, and being tender will require ſome ſhelter while young; and whoever obſerves the method here laid down, will find the plants ſo managed to gain two years growth in ſix, from thoſe raiſed in the open air, and be in leſs danger of being deſtroyed; and as the trouble and expence in raiſing them this way is not great, ſo it is worth practiſing, ſince in a few years the trees will recompenſe the trouble.

The timber of this tree is of a reddiſh colour, and very ſweet, and is commonly known in England by the name of Cedar Wood; though there are divers ſorts of wood called by that name, which come from very different trees, eſpecially in the Weſt-Indies, where there are ſeveral trees of vaſtly different appearances and genera, which have that appellation: it is this wood which is uſed for pencils, as alſo to wainſcot rooms, and make ſtair-caſes, it enduring longer ſound than moſt other ſorts of timber, which, perhaps, may be owing to ſome extreme bitter taſte in the reſin, with which the tree abounds; for it is very remarkable, that the worms do not eat the bottoms of the veſſels built with this wood, as they do thoſe built with Oak; ſo that the veſſels built with Cedar are much preferable to thoſe built with any other ſort of timber, for the uſe of the Weſt-India ſeas, but they are not fit for ſhips of war, the wood being ſo brittle as to ſplit to pieces with a cannon ball.

The Jamaica Juniper is more impatient of cold than the Bermudas, ſo will not live through the winter in the open air in England, and the plants muſt be preſerved in pots and houſed in the winter; this is propagated by ſeeds, in the ſame way as the Bermudas Cedar; but if the pots are plunged into a moderate hot-bed the ſecond ſpring after the ſeeds are ſown, it will bring up the plants ſooner, and they will have more time to get ſtrength before winter.

All the other ſorts are hardy enough to live in the open air, ſo are very well worth propagating, as they will add to the variety of Evergreen plantations; ſome of the ſorts will riſe to a very conſiderable height, ſo may prove to be uſeful timber, and may be adapted to ſuch ſoils as will not ſuit many other trees.

The common Savin ſhould not be neglected, becauſe it is ſo very hardy as never to be injured by the ſevereſt froſt; and as this ſpreads its branches near the ground, ſo if the plants are placed on the borders of woods, they will have a good effect in winter, by ſcreening the nakedneſs of the ground from ſight.

All theſe ſorts are propagated by their ſeeds, which may be ſown in the ſame way as the common Juniper, and the plants afterward ſo managed; and moſt of the ſorts may be propagated by cuttings, which, if planted in autumn in a ſhady border will take root; but thoſe plants which are raiſed from cuttings will never grow ſo upright, nor to ſo large a ſize as the plants which are raiſed from ſeeds; ſo that when theſe can be procured, it is much the better method, but the other is frequently practiſed on thoſe ſorts which do not perfect their ſeeds in England.

As ſeveral of theſe ſorts grow to the height of eighteen or twenty feet, the procuring as many of the ſorts as can be gotten from the countries of their growth, will be adding to the variety of our Evergreen plantations, which cannot be too much propagated in England, where, in general, our winters are temperate enough for them to thrive to advantage; and as the ſorts which are a little more tender than the others obtain ſtrength, they will be in leſs danger of ſuffering by ſevere winters, as we find by many other plants, which were ſo tender as not to live in the open air at firſt, but now defy the ſevereſt cold of our climate.

JUSSIÆA. Lin. Gen. Plant. 478.

The Characters are,

It hath a ſmall permanent empalement, divided into five ſegments at the top, ſitting upon the germen. The flower has five roundiſh ſpreading petals, and ten ſhort ſlender ſtamina, terminated by roundiſh ſummits. The oblong germen ſupports a ſlender ſtyle, crowned by a flat ſtigma, marked with five ſtripes. The germen afterward becomes a thick oblong capſule, crowned by the empalement, which opens lengthways, and is filled with ſmall ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's tenth claſs, intitled Decandria Monogynia, which includes the plants whoſe flowers have ten ſtamina and one ſtyle.

The Species are,

1. Jussiæa (*Suffruticoſa*) erecta villoſa, floribus tetrapetalis, decandriis ſeſſilibus. Lin. Sp. Plant. 555. *Upright hairy Juſſiæa, with flowers ſitting cloſe to the ſtalks, having four petals and ten ſtamina.* Lyſimachia Indica non pappoſa, flore luteo minimo, ſiliquis caryophyllum aromaticum æmulantibus. H. L. 396. *Indian Primroſe with a very ſmall yellow flower, and pods reſembling Cloves.*
2. Jussiæa (*Pubeſcens*) villoſa, caule erecto ramoſo, floribus pentapetalis, decandriis ſeſſilibus. *Hairy Juſſiæa with an erect branching ſtalk, flowers having five petals, and ten ſtamina which ſit cloſe to the ſtalk.* Lyſimachia lutea erecta, non papposa major, foliis hirſutis, fructu caryophylloide. Sloan. Cat. Jam. 85. *Yellow upright larger Tree-Primroſe with hairy leaves, and a fruit like Cloves.*
3. Jussiæa (*Erecta*) erecta glabra, floribus tetrapetalis octandris ſeſſilibus. Flor. Zeyl. 170. *Smooth upright Juſſiæa with four petals, and eight ſtamina to the flowers, which ſit cloſe to the ſtalk.* Lyſimachia lutea non papposa, erecta, foliis glabris, fructu caryophylloide. Sloan. Cat. Jam. 85. *Yellow upright Tree-Primroſe with ſmooth leaves, and a fruit like Cloves.*
4. Jussiæa (*Onagra*) caule erecta ramoſo glabro, floribus tetrapetalis octandris ſeſſilibus, foliis lanceolatis. *Juſſiæa with an upright, branching, ſmooth ſtalk, flowers having four petals, and eight ſtamina ſitting cloſe to the ſtalk, and ſpear-ſhaped leaves.* Onagra foliis perſicariæ amplioribus, parvo flore luteo. Plum. Cat. 7. *Tree-Primroſe with a large Arſeſmart leaf, and a ſmall yellow flower.*
5. Jussiæa (*Hirſuta*) caule erecto ſimplici hirſuto, foliis lanceolatis, floribus pentapetalis decandris ſeſſilibus. *Juſſiæa with a ſingle, upright, hairy ſtalk, ſpear-ſhaped leaves, and flowers which have five petals, and ten ſtamina ſitting cloſe to the ſtalk.* Onagra erecta, caule rubro hirſuto, foliis oblongis, flore magno luteo. Houſt. MSS. *Upright Primroſe with a hairy leaf of a reddiſh colour, oblong leaves, and a large yellow flower.*

The firſt ſort grows naturally at Campeachy, from whence the ſeeds were ſent me by the late Mr. Robert Millar; this riſes with a ſhrubby ſtalk near three feet high, ſending out ſeveral ſide branches, which are garniſhed with oblong hairy leaves placed alternate. The flowers come out from the ſide of the ſtalks ſingly, having ſhort foot-ſtalks; they have four ſmall yellow petals with eight ſtamina; theſe ſit upon the germen, which afterward becomes an oblong ſeed-veſſel, crowned by the four-leaved empalement, and has a great reſemblance to Cloves. This plant flowers in July and Auguſt, and the ſeeds ripen in October.

The ſecond ſort grows naturally in Jamaica. The ſeeds of this were ſent me by the late Dr. Houſtoun; this riſes with a hairy branching ſtalk two feet high, and is garniſhed with narrow ſpear-ſhaped leaves, placed alternate. The flowers come out toward the end of the branches ſingly from the wings of the leaves, ſitting cloſe to the ſtalk; they are compoſed of five pretty large yellow petals, and ten ſtamina; theſe ſit upon a long germen, which afterward becomes the ſeed-veſſel, crowned by the empalement; theſe are filled with ſmall ſeeds. It flowers and ſeeds about the ſame time with the laſt.

The third ſort grows naturally in Jamaica, from whence the ſeeds were ſent me with thoſe of the former ſort; this riſes with a ſmooth erect ſtalk three feet high, garniſhed with long, narrow, ſmooth, ſpear-ſhaped leaves. The flowers are large and yellow, ſitting cloſe to the ſtalk; theſe are ſucceeded by long ſeed-veſſels, ſhaped like thoſe of the other ſorts. It flowers and ſeeds at the ſame time with the former.

The fourth ſort was ſent me from Carthagena by the late Dr. Houſtoun; this hath a branching ſmooth ſtalk near three feet high, garniſhed with ſpear-ſhaped leaves, ſtanding upon ſhort foot-ſtalks. The flowers are ſmall, yellow, and are compoſed of four petals and eight ſtamina; theſe ſit very cloſe to the ſtalk, and are ſucceeded by ſeed-veſſels, ſhaped like thoſe of the former ſorts.

The fifth ſort was ſent me from La Vera Cruz, by the late Dr. Houſtoun; this riſes with ſingle upright red ſtalks three feet high, which are hairy and channelled. The leaves are ſpear-ſhaped, and placed alternate on the ſtalks, ſtanding nearer together than in any of the other ſorts. The flowers come out from the wings of the leaves, toward the top of the ſtalk; they are compoſed of five large yellow petals, and ten ſtamina ſitting cloſe to the ſtalks, and are ſucceeded by ſeed-veſſels which are one inch long, and ſhaped like thoſe of the former ſorts.

The firſt, ſecond, and fourth ſorts are annual plants, at leaſt they are ſo in England; for if the plants are raiſed early in the ſpring, they will flower in July, and ripen their ſeed the beginning of October; and thoſe plants which are raiſed later in the ſpring, cannot be preſerved through the winter, though they are placed in a warm ſtove; nor do their ſtalks ever grow ligneous, or ſhew any ſigns of their being perennial in their native country.

The third and fifth ſorts have continued through the winter in the bark-ſtove, but thoſe have been ſuch plants as did not flower and ſeed the firſt year; for after they had perfected ſeeds, the following ſummer the plants decayed.

All theſe ſorts are propagated by ſeeds, which ſhould be ſown early in the ſpring, in pots filled with a ſoft loamy ſoil, and plunged into a moderate hot-bed; but as theſe ſeeds often lie a whole year in the ground before they vegetate, the earth muſt be kept moiſt, and the glaſſes of the hot-bed ſhaded in the heat of the day, by this method the ſeeds may be brought ſoon to vegetate; when the plants come up, and are fit to remove, they ſhould be each planted into a ſmall ſeparate pot, filled with light loamy earth, and plunged into a hot-bed of tanners bark, where they ſhould be ſhaded from the ſun till they have taken new root; after which they ſhould have free air admitted to them every day, in proportion to the warmth of the ſeaſon; they muſt alſo be frequently refreſhed with water, but it muſt not be given to them in too great plenty: when the roots of the plants have filled theſe ſmall pots, the plants ſhould be removed into others a ſize larger; and if the plants are too tall to ſtand under the frames of the hot-bed, they ſhould be removed into the bark-ſtove, where they may remain to flower and perfect their ſeeds; for when the plants riſe early in the ſpring, and are brought forward in hot-beds, all the ſorts will flower and perfect their ſeeds the ſame year, which is better than to have them to keep through the winter.

JUSTICIA. Houſt. Nov. Gen. Lin. Gen. Plant. 27. Adhatoda. Tourn. Inſt. R. H. 175. tab. 79. This plant was ſo named by the late Dr. Houſtoun, in honour of James Juſtice, Eſq; a great lover and encourager of gardening and botany.

The CHARACTERS are,

The empalement of the flower is ſmall, and divided into five acute ſegments at the top. The flower hath one petal, which is divided into two lips almoſt to the bottom, which are entire. The upper lip is raiſed archways, and the under is reflexed. It hath two awl-ſhaped ſtamina ſituated under the upper lip, terminated by erect ſummits which are bifid at their baſe. It hath an oblong germen, ſupporting a ſlender ſtyle which is longer than the petal, crowned by a ſingle ſtigma. The germen afterward becomes an oblong capſule with two cells, divided by a partition, which is contrary to the two valves, which open with an elaſticity, and caſt out the roundiſh ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's ſecond claſs, intitled Diandria Monogynia, which includes thoſe plants whoſe flowers have two ſtamina and one ſtyle. To this genus of Dr. Houſtoun's is joined the Adhatoda of Tournefort, but there is a diſtinction in their flowers; the two lips of Juſticia are entire, but the upper lip of Adhatoda is indented at the end, and the under is divided into three parts; and in the capſule of Juſticia there are ſeldom more than two ſeeds, but in Adhatoda ſeveral.

The SPECIES are,

1. JUSTICIA (*Scorpioides*) foliis oblongo-ovatis hirſutis, ſeſſilibus, floribus ſpicatis alaribus, caule fruticoſo. *Juſticia with oblong, oval, hairy leaves ſitting cloſe to the ſtalks, and flowers growing in ſpikes proceeding from the ſide of the ſtalks, which are ſhrubby.* Juſticia frutescens, floribus ſpicatis majoribus, uno verſu diſpoſitis. Houſt. MSS. *Shrubby Juſticia with larger flowers growing in ſpikes, which are ranged on one ſide.*
2. JUSTICIA (*Sexangularis*) caule erecto ramoſo hexangulari, foliis ovatis oppoſitis, bracteis cuneiformibus confertis. *Juſticia with an erect branching ſtalk, having ſix angles, oval leaves placed oppoſite, and wedge-ſhaped ſmall leaves (or bracteæ) growing in cluſters.* Juſticia annua hexangulari caule, foliis Circææ conjugatis, flore miniato. Houſt. MSS. *Annual Juſticia with an hexangular ſtalk, Enchanters Nightſhade leaves ſet by pairs, and a carmine flower.*
3. JUSTICIA (*Fruticoſa*) foliis ovato-lanceolatis, pediculatis, hirſutis, bracteis cordatis acuminatis, caule fruticoſo. *Juſticia with oval ſpear-ſhaped leaves growing on foot-ſtalks, heart-ſhaped acute-pointed bracteæ, and a ſhrubby ſtalk.* Juſticia fruteſcens & hirſuta, foliis oblongis pediculis longiſſimis, flore rubro. Houſt. MSS. *Shrubby and hairy Juſticia with oblong leaves growing on very long foot-ſtalks, and a red flower.*
4. JUSTICIA (*Adhatoda*) arborea, foliis lanceolato-ovatis, bracteis ovatis perſiſtentibus, corollarum galeâ concavâ. Flor. Zeyl. 16. *Tree-Juſticia with oval ſpear-ſhaped leaves, oval permanent bracteæ, and a concave helmet to the flower.* Adhatoda Zeylanenſium. H. L. 642. *Adhatoda of Ceylon, commonly called Malabar Nut.*
5. JUSTICIA (*Hyſſopifolia*) fruticoſa, foliis lanceolatis integerrimis, pedunculis trifloris ancipitibus, bracteis calyce brevioribus. Lin. Sp. Plant. 15. *Shrubby Juſticia with entire ſpear-ſhaped leaves, foot-ſtalks having three flowers placed different ways, and a bractea ſhorter than the empalement.* Adhatoda Indica, folio ſaligno, flore albo. Boerh. Ind. alt. 1. 239. *Indian Adhatoda with a Willow leaf and white flower, commonly called Snap-tree.*
6. JUSTICIA (*Spinoſa*) ſpinoſa, foliis oblongo-ovatis emarginatis, caule fruticoſo ramoſo. *Prickly Juſticia with oblong oval leaves indented at their edges, and a ſhrubby branching ſtalk.* Adhatoda Antegoana, Lycii facie, ſpinoſa. Petiv. *Prickly Adhatoda of Antigua, with the appearance of Boxthorn.*
7. JUSTICIA (*Arborea*) arborea, foliis lanceolato-ovatis ſeſſilibus, ſubtus tomentoſis, floribus ſpicatis congeſtis terminalibus. *Tree-Juſticia with ſpear-ſhaped oval leaves,*

woolly on their under ſide, ſitting cloſe to the ſtalks, with ſpikes of flowers growing in cluſters at the ends of the branches. Adhatoda arborea, foliis oblongis, ſubtus villoſis, floribus ſpicatis albis. Houſt. *Tree-Adhatoda with oblong leaves, hairy on their under ſide, and ſpikes of white flowers.*

8. Justicia (*Ecbolium*) arborea, foliis lanceolato ovatis, bracteis ovatis deciduis mucronatis, corollarum galeâ reflexâ. Flor. Zeyl. 17. *Tree-Juſticia with ſpear-ſhaped oval leaves, oval-pointed bracteæ which fall off, and a reflexed helmet to the flowers.* Adhatoda ſpicâ longiſſimâ, flore reflexo. Burman. Zeyl. 7. tab. 4. f. 1. *Adhatoda with a very long ſpike, and a reflexed flower.*

The firſt ſort was diſcovered growing naturally at La Vera Cruz, by the late Dr. Houſtoun, who ſent the ſeeds to England; this riſes with a ſhrubby brittle ſtalk five or ſix feet high, ſending out many branches, which are garniſhed with oblong oval leaves, two inches long, and one inch broad, which are hairy and placed oppoſite; from the wings of the leaves come out the ſpikes of flowers, which are reflexed like a ſcorpion's tail. The flowers are large, of a carmine colour, and ranged on one ſide of the ſpike; theſe are ſucceeded by ſhort pods about half an inch long.

The ſecond ſort was diſcovered by the ſame gentleman, in the ſame country; this is an annual plant with an upright ſtalk, having ſix angles, which riſes two or three feet high, dividing into many branches, garniſhed with oval leaves placed oppoſite, an inch and a half long, and one inch broad; they are ſmooth, as are alſo the ſtalks. At each joint come out cluſters of ſmall wedge-ſhaped leaves, which are by Dr. Linnæus termed bracteæ, and long before the ſtalks decay, moſt of the larger leaves fall off, ſo there are only theſe ſmall leaves remaining. The flowers are produced in ſmall ſpikes at the ſide of the branches, ſitting very cloſe among the leaves; they are of a beautiful carmine colour, and have but one petal, which has two lips. The upper lip is arched, bending over the lower, which is alſo a little reflexed, but both are entire. The flowers are ſucceeded by ſhort wedge-ſhaped capſules, opening lengthways, incloſing two ſmall oval ſeeds.

The third ſort was diſcovered by the ſame gentleman at Campeachy; this riſes with a hairy ſhrubby ſtalk four or five feet high, dividing into ſeveral branches, garniſhed with oval, ſpear-ſhaped, hairy leaves, four inches long, and two inches and a half broad, ſtanding upon foot-ſtalks which are above an inch long, placed oppoſite. At the baſe of the foot-ſtalks come out a cluſter of ſmall heart-ſhaped leaves, ending in acute points, which are termed bracteæ. The flowers come out in looſe cluſters from the wings of the ſtalks, toward the end of the branches; they are of a pale red colour, and ſhaped like thoſe of the former ſort.

Theſe plants are propagated by ſeeds, which ſhould be ſown early in the ſpring, in ſmall pots filled with freſh light earth, and plunged into a moderate hot-bed of tanners bark, obſerving to water the earth gently as it appears dry. The ſeeds of theſe plants frequently lie a year in the ground, ſo that the pots muſt not be diſturbed, if the plants do not come up the ſame year; but in the winter ſhould be kept in the ſtove, and the ſpring following plunged into a freſh hot-bed, which will bring up the plants if the ſeeds were good. When the plants begin to appear, the glaſſes of the hot-bed ſhould be raiſed every day, when the weather is warm, to admit freſh air to them. The plants muſt alſo be frequently watered in warm weather; but water ſhould not be given in large quantities while the plants are young, becauſe they are then very tender, and ſubject to rot at the bottom of their ſtems, with much moiſture.

When the plants are about two inches high, they ſhould be carefully taken up, and each tranſplanted into a ſeparate ſmall pot filled with freſh light earth, and then plunged into the hot-bed again, being careful to water and ſhade them until they have taken new root; after which time they ſhould have air admitted to them every day, in proportion to the warmth of the ſeaſon, and ſhould be duly watered every two or three days in hot weather.

As the plants advance in their growth, they ſhould be ſhifted into larger pots, for if their roots are too much confined, the plants will not make any conſiderable progreſs; but they ſhould not be over potted, for that will be of worſe conſequence than the other; becauſe when they are planted in very large pots, they will ſtarve and decay, without producing any flowers. They are too tender to endure the open air in this country, therefore they ſhould always remain in the hot-bed, being careful to let them have a due proportion of air in hot weather; and the annual ſort ſhould be brought forward as faſt as poſſible in the ſpring, that the plants may flower early, otherwiſe they will not produce good ſeeds in England.

The firſt and third ſorts ſhould remain in the hot-bed during the ſummer ſeaſon (provided there is room under the glaſſes, without being ſcorched;) but at Michaelmas they ſhould be removed into the ſtove, and plunged into the bark-bed, where they muſt remain during the winter ſeaſon, obſerving to keep them warm, as alſo to water them gently once or twice a week, according as they ſhall require. The following ſummer theſe plants will flower, and abide ſeveral years, but they rarely produce good ſeeds in Europe.

The fourth ſort grows naturally in the iſland of Ceylon, but has been long in the Engliſh gardens, where it is commonly known at preſent by the title of Malabar Nut; but was formerly called Beetle Nut, and was by ſome ſuppoſed to be the tree of which the Chineſe chew the leaves and nuts: this, though a native of ſo warm a country, is hardy enough to live in a good green-houſe in England, without any artificial heat. It riſes here with a ſtrong woody ſtalk to the height of twelve or fourteen feet, ſending out many ſpreading branches, which are garniſhed with ſpear-ſhaped oval leaves more than ſix inches long, and three inches broad, placed oppoſite. The flowers are produced on ſhort ſpikes at the end of the branches, which are white, with ſome dark ſpots; theſe appear in July, but are not ſucceeded by any ſeeds in England.

This ſort may be propagated by cuttings, which, if planted in pots in June or July, and plunged into a very moderate hot-bed, will take root; but they muſt be every day ſcreened from the ſun, and if the external air is excluded from them, they will ſucceed better than when it is admitted to them. It may alſo be propagated by laying down their young branches, which will take root in the tubs or pots in one year; then the young plants ſhould be put each into a ſeparate pot, filled with ſoft loamy earth, and placed in the ſhade till they have taken new root, when they may be placed in a ſheltered ſituation during the ſummer, but in winter they muſt be houſed, and treated in the ſame way as Orange-trees, with only this difference, that theſe require more water.

The fifth ſort grows naturally in India; this riſes with a ſhrubby ſtalk from three to four feet high, ſending out branches on every ſide from the bottom, ſo as to form a kind of pyramid; theſe are covered with a white bark, and garniſhed with ſpear-ſhaped entire leaves, near two inches long, and one third of an inch broad; they are ſmooth, ſtiff, and of a deep green, ſtanding oppoſite. At the baſe of the foot-ſtalks come out cluſters of ſmaller leaves, of the ſame ſhape and texture. The flowers come out upon ſhort foot-ſtalks from the ſide of the branches, each foot-ſtalk ſupporting one or two white flowers, having long empalements; theſe are ſucceeded by oblong ſeed-veſſels, which, when ripe, caſt out their ſeeds with an elaſticity, from whence it had the title of Snap-tree.

This is propagated by cuttings during any of the ſummer months; they ſhould be planted in pots filled with light loamy earth, and plunged into a moderate hot-bed, and ſhaded from the ſun, and now and then gently refreſhed with water, and not too much air admitted to them. In about two months the cuttings will have taken root, then they muſt be gradually inured to bear the open air, into which they ſhould be removed, placing them in a ſheltered ſituation, where they may ſtay till autumn; but if they get root pretty early in the ſummer, it will be proper to ſeparate them each into a ſingle ſmall pot, ſetting them in the ſhade till they have taken new root, after which they may be placed as before directed; but when it is late in the ſeaſon before they take root, it will be better to let them remain in the ſame pots till the following ſpring. In winter theſe plants muſt be placed in a warm green-houſe, or in a moderately warm ſtove, for they are impatient of cold and damp, nor will they thrive in too much warmth; they will often require water in winter, but during that ſeaſon it muſt be given them moderately; in ſummer they muſt be removed into the open air, but ſhould have a warm ſheltered ſituation, and in warm weather they muſt have plenty of water. This plant flowers at different ſeaſons, but never produces fruit here.

The ſixth ſort grows naturally in Jamaica, from whence the late Dr. Houſtoun ſent it to England; this riſes with many ſhrubby ſlender ſtalks about five feet high, ſending out branches on every ſide from the root upward, which grow erect, and are covered with a whitiſh bark, garniſhed with ſmall, oblong, oval leaves, coming out on each ſide the ſtalk oppoſite, and under the leaves are placed at every joint two ſharp thorns like thoſe of the Berberry; the flowers come out ſingly from the wings of the leaves, they are ſmall, and of a pale red colour, ſhaped like thoſe of the other ſorts.

The ſeventh ſort was found by the late Dr. Houſtoun, growing naturally at Campeachy. This riſes with a ſtrong woody ſtem twenty feet high, dividing into many crooked irregular branches, covered with a light brown bark, garniſhed with ſpear-ſhaped oval leaves, near four inches long and two broad, which are covered with a ſoft down on their under ſide. The flowers grow in ſpikes from the end of the branches, three, four, or five of theſe ſpikes ariſing from the ſame point, the middle ſpike being near three inches long, and the others about half that length. The flowers are ſmall and white, but ſhaped like thoſe of the other ſpecies.

The eighth ſort grows naturally at Malabar and in Ceylon; this riſes in its native ſoil with a ſtrong woody ſtem ten or twelve feet high, dividing into many branches, which are garniſhed with ſpear-ſhaped oval leaves five inches long, and two and a half broad, of a lucid green, placed oppoſite. The flowers grow in very long ſpikes from the end of the branches, they are of a greeniſh colour with a ſhade of blue; the helmet of the flower is reflexed.

Theſe three ſorts are propagated by ſeeds in the ſame manner as the three firſt, and the plants muſt be treated in the ſame way, eſpecially while they are young; but afterward the eighth ſort may be more hardily treated, when they have gotten ſtrength. This ſort may alſo be propagated by cuttings, in the ſame manner as the fifth ſort; and when the plants are two or three years old, they will thrive in a moderate degree of warmth in winter, and in the ſummer they may be placed abroad for two months in the warmeſt ſeaſon of the year; but they ſhould have a warm ſheltered ſituation, and when the nights begin to grow cold, they muſt be removed into the ſtove, but they muſt have free air admitted to them at all times when the weather is warm. The other two ſorts ſhould conſtantly remain in the bark-ſtove, and require the ſame treatment as other tender plants from the warmeſt countries.

IXIA. Lin. Gen. Plant. 54. Siſyrinchium. Com. Hort. Amſt.

The Characters are,

It hath oblong permanent ſpathæ (or ſheaths) which incloſe the germen; the flower has ſix oblong ſpear-ſhaped petals which are equal, and three awl-ſhaped ſtamina which are ſhorter than the petals, ſituated at equal diſtances, terminated by ſingle ſummits. It hath an oval three-cornered germen ſituated below the flower, ſupporting a ſingle ſtyle which is the length of the ſtamina, crowned by a thick trifid ſtigma; the germen afterward becomes an oval three-cornered capſule with three cells, filled with roundiſh ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's third claſs, intitled Triandria Monogynia, which includes thoſe plants whoſe flowers have three ſtamina and one ſtyle.

The Species are,

1. Ixia (*Chinenſis*) foliis enſiformibus, floribus remotis panicula dichotoma, floribus pedunculatis. Hort. Upſal. 16. *Ixia with ſword-ſhaped leaves, and flowers ſtanding remote in forked panicles upon foot-ſtalks.* Bermudiana iridis folio majori flore croceo, eleganter punctato. Krauſ. Hort. 25. tab. 25. *Bermudiana with a larger Iris leaf, and a Saffron-coloured flower, which is beautifully ſpotted.*
2. Ixia (*Africana*) floribus capitatis, ſpathis laceris. Lin. Sp. Plant. 36. *Ixia with flowers growing in heads, having ragged ſheaths.* Bermudiana Capenſis, capitulis lanugipoſis. Pet. Hort. Sicc. 242. *Bermudiana from the Cape of Good Hope, with woolly heads.*
3. Ixia (*Scillariis*) foliis gladiolatis, nervoſis, hirſutis, floribus ſpicatis terminalibus. Icon. tab. 155. fig 1. *Ixia with ſword-ſhaped, hairy, veined leaves, and flowers growing in ſpikes at the ends of the ſtalks.*
4. Ixia (*Polyſtacia*) foliis lineari-gladiolatis, floribus alaribus & terminalibus. Icon. tab. 155. fig. 2. *Ixia with narrow ſword-ſhaped leaves, and flowers proceeding from the ſides and tops of the ſtalk.*
5. Ixia (*Crocata*) foliis gladiolatis glabris, floribus corymboſis terminalibus. Icon. tab. 156. *Ixia with ſmooth ſpear-ſhaped leaves, and flowers growing in a corymbus terminating the ſtalk.* Siſyrinchium Africanum majus, flore luteo maculâ notato. Olden. *Greater African Siſyrinchium with a yellow ſpotted flower.*
6. Ixia (*Bulbifera*) foliis lineari-gladiolatis, floribus alternis, caule bulbifero. *Ixia with narrow ſword-ſhaped leaves, flowers placed alternate, and ſtalks bearing bulbs.*
7. Ixia (*Sparſa*) foliis gladiolatis, floribus diſtantibus. *Ixia with ſword-ſhaped leaves, and flowers growing diſtant.*
8. Ixia (*Flexuoſa*) foliis lineari-gladiolatis, floribus ſpicatis ſeſſilibus terminalibus. *Ixia with narrow ſword-ſhaped leaves, and ſeſſile flowers growing in ſpikes at the top of the ſtalk.*

The firſt ſort grows naturally in India, where the ſtalks riſe to the height of five or ſix feet, but in England they are ſeldom more than half that height. It hath a pretty thick fleſhy root, divided in knots or joints of a yellowiſh colour, ſending out many fibres; the ſtalk is pretty thick, ſmooth, and jointed, garniſhed with ſword-ſhaped leaves a foot long and one inch broad, with ſeveral longitudinal furrows embracing the ſtalks with their baſe, ending in acute points; the upper part of the ſtalk divaricates into two ſmaller, with a foot-ſtalk ariſing between them, which ſupports one flower; the ſmaller branches divaricate again in the ſame manner into foot-ſtalks, which are two inches long, each ſuſtaining one flower. At each of theſe joints is a ſpatha or ſheath embracing the ſtalk, which at the lower joints are three inches long, but the upper are not more than one inch, ending in acute points which are permanent; the flowers are compoſed of ſix equal petals, of a yellow colour within, and variegated with dark red ſpots; the outſide is of an Orange colour. Theſe appear in July and Auguſt, and in warm ſeaſons are ſucceeded by ſeeds.

This ſort may be propagated either by ſeeds or parting of the roots: if by ſeeds they ſhould be ſown in pots, and plunged into a moderate hot-bed, which will bring up the plants much ſooner than when they are ſown in the full ground; when the plants are fit to remove, they ſhould be each planted in a ſmall ſeparate pot filled with light earth, and if they are placed under a frame till they have taken good root in the pots, it will greatly forward their growth; afterward they may be placed in the open air in a ſheltered ſituation, where they may remain till the autumn, when they muſt be placed under a frame to ſcreen them from froſt; and in the ſpring moſt of the plants may be turned out of the pots and planted in a warm border, where they will abide through the common winters very well, but in ſevere froſts they are often killed, unleſs they are covered with tan, or other covering to keep out the froſt; therefore a few of the plants may be kept in pots, and ſheltered under a frame in winter.

The ſtalks and leaves of this plant decay to the root in autumn, ſo that if the ſurface of the ground about the roots is covered two or three inches thick with tan, it will ſecure them from the danger of froſt; and in the ſpring, before the roots ſhoot, will be the beſt time to remove and part the roots; but this ſhould not be done oftener than every third year, for when they are often parted they will be weak, and will not flower ſo well.

The ſecond ſort grows naturally at the Cape of Good Hope; this is a low plant, which rarely riſes more than three or four inches high; the leaves are narrow and veined, the flowers are ſmall, growing in a downy head on the top of the ſtalk, but they make little appearance, ſo are only kept for the ſake of variety.

The third ſort I raiſed from ſeeds, which were ſent me from the Cape of Good Hope. This hath a round bulbous root a little compreſſed, covered with a red ſkin, from which ariſe five or ſix ſword-ſhaped leaves about three or four inches long, hairy, and with ſeveral longitutinal furrows; theſe embrace each other at their baſe, but ſpread aſunder at the top; between theſe come out the flower-ſtalk, which riſes ſix or eight inches high, is naked to the top, and terminated by a cluſter of flowers, each having a ſpatha or hood, which dries and is permanent; the flowers are of a deep blue colour, and appear in May; theſe are ſucceeded by roundiſh three-cornered ſeed-veſſels with three cells, filled with roundiſh ſeeds which ripen in July, then the leaves and ſtalks decay.

The fourth ſort was raiſed from ſeeds in the Chelſea garden, which came with thoſe of the former ſort. This hath a ſmall round bulbous root, from which ariſe four or five narrow, long, ſword-ſhaped leaves, ſix or ſeven inches long; between theſe come out a very ſlender round ſtalk about ten inches long, from the ſide of which there comes out one or two cluſters of flowers, ſtanding upon ſhort foot-ſtalks, and at the top of the ſtalk the flowers grow in a looſe ſpike; they are of a pure white, and ſhaped like thoſe of the other ſpecies. Theſe appear in May, and the ſeeds ripen in July.

The ſeeds of the fifth ſort were ſent me from the Cape of Good Hope; this has an oval bulbous root which is a little compreſſed, from which come up three or four narrow, thin, ſword-ſhaped leaves, near a foot long; the flower-ſtalk riſes a little above the leaves, it is very ſlender, naked, and terminated by a round cluſter of flowers, each having a ſpatha or hood; they are compoſed of ſix pretty large oblong petals which are concave, and of a deep yellow colour, each having a large black ſpot at the baſe. This flowers early in May, and the ſeeds ripen the latter end of June.

The ſixth ſort hath narrow ſpear-ſhaped leaves about ſix or ſeven inches long; the ſtalk riſes near a foot and a half high, garniſhed with one leaf at each of the lower joints, of the ſame ſhape with the other, but ſmaller; theſe embrace the ſtalk with their baſe, and ſtand erect; the upper part of the ſtalk is adorned with flowers, compoſed of ſix oblong oval petals of a ſulphur colour, which are placed alternate on the ſtalk, which is bent at each joint where the flowers ſtand; the flowers have three ſhort ſtamina which are joined at their baſe, terminated by long, flat, erect ſummits; the germen is ſituated under the flower, ſupporting a long ſlender ſtyle, crowned by a trifid ſtigma; the germen afterward becomes a roundiſh capſule with three cells, filled with roundiſh ſmall ſeeds. The ſtalks at each of the lower joints thruſt out ſmall bulbs, which, if planted, will grow and produce flowers.

The ſeventh ſort hath ſhorter and broader leaves than the former; the ſtalk is ſlender and furrowed, and at each of the lower joints is garniſhed with one leaf of the ſame ſhape, embracing the ſtalk with their baſe; the flowers come out toward the top of the ſtalk, at two or three inches diſtance, each ſtalk ſupporting two or three ſulphur-coloured flowers, which are each compoſed of ſix ſpear-ſhaped petals an inch and a half long, equal in their ſize and regular in poſition; they have a ſhort permanent empalement, cut into two long and two ſhorter acute ſegments; theſe are ſucceeded by round capſules with three cells, filled with round ſeeds. This ſort flowers in March, and the ſeeds ripen about two months after.

The eighth ſort hath very ſmall, round, bulbous roots, from which ariſe three or four long, ſlender, Graſs-like leaves, of a dark green colour; between theſe come out the ſtalk, which is very ſlender and round, riſing a foot and a half high; at the top the flowers are collected in a ſpike ſitting cloſe to the ſtalk, each having a thin, dry, permanent ſpatha or ſheath, which covers the capſule after the flower is fallen. The flowers are of a pure white, and ſhaped like thoſe of the other ſpecies, but are ſmaller; they are ſucceeded by ſmall round ſeed-veſſels with three cells, each containing two or three round ſeeds. It flowers the latter end of May, and the ſeeds ripen in July.

There are ſome other varieties of this genus, which have flowered in the Chelſea garden, differing only in the colour of their flowers, ſo are not ſuppoſed to be diſtinct ſpecies; one of which is purple on the outſide, and white within; another has white flowers, with a blue ſtripe on the outſide of each petal, and a third has white flowers with yellow bottoms. Theſe have already flowered in the Chelſea garden, where there are many more, which have been ſince raiſed from ſeeds, whoſe flowers have not as yet appeared; and at the Cape of Good Hope, where theſe plants grow naturally, there are more than thirty varieties mentioned in a catalogue of Dr. Herman's. The roots of moſt, if not all theſe ſorts, are frequently eaten by the inhabitants at the Cape of Good Hope, who greatly eſteem them.

All the ſorts multiply very faſt by offſets, ſo that when once obtained, there will be no occaſion to raiſe them from ſeeds; for the roots put out offſets in great plenty, moſt of which will flower the following ſeaſon, whereas thoſe from ſeeds are three or four years before they flower. Theſe plants will not live through the winter in the full ground in England, ſo ſhould be planted in ſmall pots filled with light earth, and placed under a frame in winter, where they may be protected from froſt, but in mild weather ſhould enjoy the free air; but during the winter they muſt be guarded from mice, who are very fond of theſe roots, and if not prevented will devour them.

IXORA. Lin. Gen. 131. Jaſminum. Burman.

The CHARACTERS are,

It hath a ſmall permanent empalement cut into four ſegments; the flower has one funnel-ſhaped petal, having a ſlender tube, cut into four ſegments at the top. It hath four ſhort ſtamina ſituated in the diviſions of the petal, terminated by oblong ſummits, and a roundiſh germen ſituated at the bottom of the involucrum, ſupporting a ſlender ſtyle the length of the tube, crowned by a bifid ſtigma; the germen afterward becomes a berry with two cells, containing two convex angular ſeeds.

This genus of plants is ranged in the firſt order of Linnæus's fourth claſs, intitled Tetrandria Monogynia, the flowers having four ſtamina and one ſtyle.

The SPECIES are,

1. IXORA (*Coccinea*) foliis ovatis ſemiamplexicaulibus, floribus faſciculatis. Flor. Zeyl. 22. *Ixora with oval leaves half embracing the ſtalks, and flowers growing in bunches.* Jaſminum Indicum lauri folio, inodorum umbellatum, floribus coccineis. Pluk. Phyt. tab. 59. f. 2.

2. **Ixora** (*Alba*) foliis ovato-lanceolatis, floribus faſciculatis. Lin. Sp. 160. *Ixora with oval ſpear-ſhaped leaves, and flowers growing in bunches.* Jaſminum Indicum, lauri folio, inodorum, floribus albicantibus & ſchetti album. Pluk. Phyt. 109. f. 2.

3. **Ixora** (*Americana*) foliis ternis lanceolato-ovatis, floribus thyrſoideis. Amœn. Acad. 5. p. 393. *Ixora with oval ſpear-ſhaped leaves placed by threes, and flowers in a looſe ſpike.* Pavetta foliis oblongo-ovatis oppoſitis, ſtipulis ſetaceis. Brown. Jam. tab. 6. f. 2.

The firſt ſort grows naturally in India, where it riſes with a woody ſtalk five or ſix feet high, ſending out many ſlender branches covered with a brown bark, garniſhed with oval leaves, placed ſometimes oppoſite, and at others there are three or four at each joint. The flowers terminate the branches in cluſters; they have very long ſlender tubes, are cut into four oval ſegments at the top, and are of a deep red colour.

The ſecond ſort grows alſo in India; this hath a woody ſtalk riſing ſix or ſeven feet high, ſending out weak branches, garniſhed with oval ſpear-ſhaped leaves placed oppoſite, ſitting cloſe to the branch; the flowers terminate the branches in ſmall cluſters; they have long ſlender tubes, divided into four ſegments at the top, and are white, without ſcent.

The third ſort grows naturally in Jamaica, and ſome other iſlands in the Weſt-Indies, where it is called Wild Jaſmine. This riſes with a ſhrubby ſtalk four or five feet high, ſending out ſlender branches oppoſite, which are garniſhed with oval ſpear-ſhaped leaves placed oppoſite, which are ſix inches long, and two inches and a half broad, having ſhort foot-ſtalks; the flowers are produced at the end of the branches in a looſe ſpike, they are white, and have a ſcent like Jaſmine.

Theſe plants are propagated by ſeeds, when they can be procured from the countries where they grow naturally, for they do not perfect any ſeeds in England. They ſhould be ſown in ſmall pots as ſoon as they arrive, and plunged into a hot-bed; if they arrive in autumn or winter, the pots may be plunged in the tan-bed in the ſtove, between the other pots of plants, ſo will take up little room; but when they arrive in the ſpring, it will be beſt to plunge them in a tan-bed under frames; the ſeeds will ſometimes come up in about ſix weeks, if they are quite freſh; otherwiſe they will lie in the ground four or five months, and ſometimes a whole year, therefore the earth ſhould not be thrown out of the pots till there is no hopes of their growing; when the plants come up, and are fit to remove, they ſhould be each planted in a ſeparate ſmall pot, filled with light earth, and afterward treated in the manner directed for the Coffee-tree.

They may alſo be increaſed by cuttings during the ſummer months, and planted in ſmall pots plunged into a moderate hot-bed, covering them cloſe either with bell or hand-glaſſes to exclude the external air, ſhading them carefully from the ſun during the heat of the day, until they have put out good roots, when they ſhould be parted, and each put into a ſeparate pot, treating them as the ſeedling plants.

K.

KALI. See Salsola.

KALMIA. Lin. Gen. Plant. 482. Chamærhododendros. Tourn. Inſt. R. H. 604. tab. 373.

The Characters are,

The flower has a ſmall permanent empalement cut into five parts, and one petal cut into five ſegments, which ſpread open and are roundiſh. It hath ten ſtamina the length of the petal, which decline in the middle, terminated by oval ſummits. In the center is ſituated a roundiſh germen, ſupporting a ſlender ſtyle as long as the petal, crowned by an obtuſe ſtigma. The germen afterward becomes an oval or globular capſule with five cells, filled with very ſmall ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's tenth claſs, intitled Decandria Monogynia, which includes thoſe plants whoſe flowers have ten ſtamina and one ſtyle.

The Species are,

1. **Kalmia** (*Latifolia*) foliis ovatis, corymbis terminalibus. Amœn. Acad. 3. p. 19. *Kalmia with oval leaves, and flowers growing in bunches terminating the branches.* Chamædaphne foliis tini, floribus bullatis umbellatis. Cateſb. Carol. 2. p. 98. tab. 98. *Dwarf Laurel with a Tinus leaf, and ſtudded flowers growing in umbels, commonly called Ivy-tree in America.*
2. **Kalmia** (*Anguſtifolia*) foliis lanceolatis corymbus lateralibus. Lin. Gen. Nov. 1079. *Kalmia with ſpear-ſhaped leaves, and flowers growing in round bunches on the ſides of the ſtalk.* Chamædaphne ſempervirens, foliis oblongis anguſtis, foliorum faſciculis oppoſitis. Cateſb. Carol. 3. p. 17. *Evergreen Dwarf Laurel, with oblong narrow leaves growing in bunches, which are placed oppoſite.*

The firſt ſort grows naturally upon rocks and in barren ſoils in Virginia and Penſylvania, where it riſes with a branching ſtalk to the height of ten or twelve feet, garniſhed with very ſtiff leaves, which are two inches long and one broad, of a lucid green on their upper ſide, but of a pale green on their under; they have ſhort foot-ſtalks, and ſtand without order round the branches; between theſe the buds are formed for the next year's flowers, at the extremity of the branches; theſe buds ſwell during the autumn and ſpring months, till the beginning of June, when the flowers burſt out from their empalements, forming a round bunch (or corymbus) ſitting very cloſe to the branch; they are of a pale bluſh colour, the outſide of the petal is of a Peach colour. The flower has but one petal, whoſe baſe is tubulous, but is cut into five roundiſh ſegments, ſtudded with purple ſpots, which are prominent; after the flowers are paſt, the germen in the center becomes an oval capſule, crowned by the permanent ſtyle, having five cells, which are full of very ſmall ſeeds. This ſhrub in its native ſoil continues flowering great part of the ſummer, and is one of the greateſt ornaments to the country; but as yet it is not ſo well naturalized to our climate as could be wiſhed, though the plants are not injured by the cold, and ſome of them have flowered ſeveral years paſt in the Chelſea garden.

In the country where this ſhrub grows naturally, it ſends out plenty of ſuckers from the roots, ſo that they form thickets which are almoſt impaſſable; but here they have not as yet produced any ſuckers, nor do the ſeeds come to maturity, ſo that the plants are not very common in England; for the ſeeds which are ſent from America lie in the ground a whole year before the plants appear, and afterward they make very ſlow progreſs, which has diſcouraged moſt people from attempting to raiſe the plants in that method. The only perſon who has ſucceeded well in the raiſing of theſe, is Mr. James Gordon of Mile End, who has a good number of the plants which have ariſen from ſeeds.

The ſecond ſort is a native of the ſame country with the firſt, where it riſes from three to ſix feet high, dividing into ſmall ligneous branches which are very cloſe, covered with a dark gray bark, garniſhed with ſtiff leaves about two inches long and half an inch broad, of a lucid green, placed without order upon the branches, ſtanding upon ſlender foot-ſtalks; the flowers grow in looſe bunches on the ſide of the branches, upon ſlender foot-ſtalks; they are of one petal, having a ſhort tube, but ſpread open at the top, where they are cut into five angles: the flowers are of a bright red colour when they firſt open, but afterward fade to a bluſh or Peach bloom colour; theſe are ſucceeded by roundiſh compreſſed ſeed-veſſels crowned by the permanent ſtyle, divided into five cells, which are filled with ſmall roundiſh ſeeds. This ſhrub flowers great part of ſummer in its native country, but is not yet ſo well naturalized to this country as to do the like.

The leaves of this elegant plant are ſuppoſed to have a noxious quality, deſtroying ſheep and oxen when they feed upon them, yet the deer eat them with impunity.

Both theſe ſorts multiply by their creeping roots in their native ſoil, and at Whitton, where they have ſtood unremoved a conſiderable time, they put out ſuckers in pretty great plenty; and as theſe plants which come from ſuckers, are much more likely to produce others than thoſe which are raiſed from ſeeds, and will flower much ſooner, ſo the plants ſhould not be removed, but encouraged to ſpread their roots and ſend out ſuckers.

KARATAS, the Penguin or wild Ananas.

The Characters are,

It hath a tubulous bell-ſhaped flower, which is divided into three parts at the mouth, from whoſe empalement where the germen is ſituated ariſes the pointal, fixed like a nail in the hinder part of the flower, attended by ſix ſhort ſtamina; the germen afterward becomes a fleſhy almoſt conical fruit, which is divided by membranes into three cells, that are full of oblong ſeeds.

There is but one ſort of this plant at preſent known in England, which is,

Karatas (*Penguin*) foliis ciliato ſpinoſis mucronatis, racemo terminali. *The wild Ananas or Penguin.*

Father Plumier has made a great miſtake in the figure and deſcription of the characters of this plant, and the Caraguata; for he has joined the flower of the Caraguata to the fruit of the Karatas, and vice verſâ; this has led many perſons into miſtakes, who have joined the Bromelia and Ananas to this, making them all of the ſame genus, whereas by their characters they ſhould be ſeparated.

This plant is very common in the Weſt-Indies, where the juice of its fruit is often put into punch, being of a ſharp acid flavour. There is alſo a wine made of the juice of this fruit which is very ſtrong, but it will not keep good very long, ſo is only for preſent uſe. This wine is very intoxicating and heats the blood, therefore ſhould be drank very ſparingly.

In England this plant is preſerved as a curioſity, for the fruit ſeldom arrives to any degree of perfection in this country, though it has often produced fruit in the gardens, which ſometimes has ripened pretty well; but if it were to ripen as thoroughly here as in its native country, it would be little valued on account of its great auſterity, which will often take the ſkin off from the mouths and throats of thoſe people who eat it incautiouſly.

This plant is propagated by ſeeds, for though there are often ſuckers ſent forth from the old plants, yet they come out from between the leaves, and are ſo long, ſlender, and ill-ſhapen, that if they are planted they ſeldom make regular plants. Theſe ſeeds ſhould be ſown early in the ſpring, in ſmall pots filled with light rich earth, and plunged into a hot-bed of tanners bark. When the plants are ſtrong enough to tranſplant, they ſhould be carefully taken up, and each planted into a ſeparate pot filled with light rich earth, and plunged into the hot-bed again, obſerving to refreſh them frequently with water, until they have taken new root, after which time they ſhould have air and water in proportion to the warmth of the ſeaſon. In this bed the plants may remain till Michaelmas, at which time they ſhould be removed into the ſtove, and plunged into the bark-bed, where they ſhould be treated in the ſame manner as the Ananas.

Theſe plants will not produce their fruit in England until they are three or four years old, ſo they ſhould be ſhifted into larger pots, as the plants advance in their growth; for if their roots are too much confined, they will make but little progreſs. They ſhould alſo be placed at a pretty great diſtance from each other, for their leaves will be three or four feet long, which turning downward occupy a large ſpace.

The leaves of this plant are ſtrongly armed with crooked ſpines, which renders it very troubleſome to ſhift or handle the plants; for the ſpines catch hold of whatever approaches them by their crooked form, being ſome bent one way, and others the reverſe, ſo that they catch both ways, and tear the ſkin or clothes of the perſons who handle them, where there is not the greateſt care taken of them.

The fruit of this plant is produced in cluſters, growing upon a ſtalk about three feet high, and having generally a tuft of leaves growing on the top, ſo has, at firſt ſight, the appearance of a Pine Apple; but, when cloſer viewed, they will be found to be a cluſter of oblong fruit, each being about the ſize of a finger.

A **KATKIN** is an aggregate of ſummits, hanging down in form of a rope, or Cat's tail, as in the Sallow, Hazel, Birch, &c. and is called in Latin iulus.

KÆMPFERIA. Lin. Gen. Plant. 7.

The Characters are,

It hath a ſingle ſpatha (or ſheath) of one leaf; the flower hath one petal, with a long ſlender tube, divided into ſix parts above; three of them are alternately ſpear-ſhaped and equal, the other are oval, and at bottom cut into two ſegments which are vertically heart-ſhaped. It hath but one ſtamen, which is membranaceous, oval, and indented, terminated by a linear ſummit, faſtened to it all the length, ſcarcely emerging out of the tube of the petal. It hath a round germen ſupporting a ſtyle the length of the tube, crowned by an obtuſe ſtigma; the germen afterward becomes a roundiſh three-cornered capſule with three cells, filled with ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's firſt claſs, intitled Monandria Monogynia, which includes thoſe plants whoſe flowers have one ſtamen and one ſtyle.

The Species are,

1. Kæmpferia (*Galanga*) foliis ovatis ſeſſilibus. Flor. Zeyl. 8. *Kæmpferia with oval leaves ſitting cloſe to the root.* Katſjuli Kelengu. Hort. Mal. and the Wanhom. Kæmpf. Amœn. 901. *Galangale.*
2. Kæmpferia (*Rotunda*) foliis lanceolatis petiolatis. Flor. Zeyl. 9. *Kæmpferia with ſpear-ſhaped leaves having foot-ſtalks.* Zedoaria rotunda. C. B. P. *Round Zedoary.*

Theſe plants are both natives of the Eaſt-Indies, where their roots are greatly uſed in medicine as ſudorific and carminative. The firſt ſort hath much the ſcent of green Ginger, when freſh taken out of the ground; the roots are divided into ſeveral fleſhy tubers, which are ſometimes jointed, and grow about four or five inches long; the leaves are oval, about four inches long and two broad; theſe are without foot-ſtalks, growing cloſe to the root, and ſeem as if ſet on by pairs, ſpreading open each way; and from between theſe leaves the flowers are produced ſingly, having no foot-ſtalks, but are cloſely embraced by the leaves; the flowers are white, having a bright purple bottom. Theſe are not ſucceeded by any fruit in England.

The ſecond ſort hath roots ſomewhat like thoſe of the firſt, but are ſhorter, growing in large cluſters, covered with an Aſh-coloured ſkin, but within are white; from the roots ariſe the leaves, which fold over each other at their baſe; they are ſix or eight inches long, and three broad in the middle, gradually ending in acute points; the flowers ariſe immediately from the roots, each having a ſpatha (or ſheath) at bottom cut into two ſegments, which cloſely embrace the foot-ſtalk; theſe have ſix petals, the three lower which decline downward are long and narrow, the two upper are divided ſo deeply as to appear like a flower with four petals, and the ſide petal is bifid; they are of mixed colours, blue, purple, white and red, having a fragrant odour: they flower in July and Auguſt, but do not produce ſeeds in England.

Theſe plants being natives of hot countries, will not bear the open air in England, ſo requires a warm ſtove to preſerve them through the winter; but as their leaves decay in the autumn, ſo the plants ſhould not have too much wet while they are in an inactive ſtate. If the plants are placed in the bark-ſtove, and treated in the ſame manner as is directed for the Ginger, they will thrive, and produce plenty of flowers every ſummer. They are both propagated by parting of their roots; the beſt time for this is in the ſpring, juſt before they begin to put out their leaves.

KETMIA. See Hibiscus.

KIGGELARIA. Lin. Gen. Plant. 1001. Laurus. Sterb. We have no Engliſh title for this plant.

The Characters are,

It hath male and hermaphrodite flowers ſituated on different trees; the male flowers have an empalement of one leaf, cut into five concave ſegments, and five concave petals which are longer than the empalement, ſhaped like a pitcher; each of the petals have a honey gland faſtened to their baſe, which have three obtuſe lobes and are coloured, faſtened to the tails of the petals; they have ten ſmall ſtamina, terminated by oblong ſummits. The hermaphrodite flowers have empalements and petals like the male, but few of them have ſtamina. In the center is ſituated a roundiſh germen, ſupporting five ſtyles, crowned by obtuſe ſtigmas. The germen afterward becomes a rough globular fruit with a thick cover, having one cell, filled with angular ſeeds.

This genus of plants is ranged in the ninth ſection of Linnæus's twenty-ſecond claſs, intitled Diœcia Decandria; but it ſhould be removed to his twenty-third claſs, as the hermaphrodite flowers are fruitful, tho' they are ſituated upon diſtinct plants, whoſe male flowers have ten ſtamina.

We have but one Species of this genus, viz.

Kiggelaria (*Africana.*) Hort. Cliff. 462. fol. 29. Euonymo-affinis Æthiopica ſempervirens, fructu globoſo ſcabro, foliis ſalicis rigidis ſerratis. H. L. 139. *An Ethiopian Evergreen plant reſembling the Spindle-tree, with a rough globular fruit, and ſtiff ſawed Willow leaves.*

This plant grows naturally at the Cape of Good Hope, where it riſes to be a tree of middling ſtature; but as it will not live in the open air here, they cannot be expected to grow to a great magnitude in England. There are plants of it in the Chelſea garden upward of ten feet high, with ſtrong woody ſtems and pretty large heads; the branches have a ſmooth bark, which is firſt green, but afterward changes to a purpliſh colour; the leaves are about three inches long and one broad, of a light green colour, and ſawed on their edges, ſtanding upon ſhort foot-ſtalks alternately. The flowers come out in cluſters from the ſide of the branches, and hang downward; they are of an herbaceous white colour, and appear in May, at which time the plants are thinly garniſhed with leaves, for moſt of the old leaves drop juſt before the new ones appear. The male flowers fall away ſoon after their farina is ſhed, but the hermaphrodite flowers are ſucceeded by globular fruit about the ſize of common red Cherries; the cover of theſe is very rough, and of a thick conſiſtence, opening in five valves at the top, having one cell filled with ſmall angular ſeeds. Theſe fruit have grown to their full ſize in the Chelſea garden, but the ſeeds have rarely come to maturity here.

Theſe plants were not very common in Europe ſome years paſt, being very difficult to propagate, unleſs by ſeeds, which ſome plants both in Holland and England have lately produced, ſo that they are now much more plenty than they were in both countries; for when any of the young branches are laid down, they are two years before they put out roots, and ſcarce one in five will then have any roots; nor do the cuttings ſucceed better, for not one in twenty of them will take root, when planted with the utmoſt care: the beſt time to plant the cuttings is in the ſpring, juſt before the plants begin to ſhoot; theſe ſhould be planted in pots filled with a ſoft loamy earth, and plunged into a very moderate hot-bed, covering them cloſe with a glaſs, to exclude the air from them, and ſhade them every day from the ſun; they ſhould have very little water after their firſt planting. If any of them grow, they ſhould be planted into ſeparate ſmall pots, filled with loamy earth, and may be expoſed to the air in a ſheltered ſituation till autumn, when they muſt be removed into the green-houſe, and treated in the ſame manner as Orange-trees.

KITCHEN-GARDEN. A good Kitchen-garden is almoſt as neceſſary to a country ſeat, as a kitchen to the houſe; for without one, there is no way of being ſupplied with a great part of neceſſary food; the markets in the country being but poorly furniſhed with eſculent herbs, and thoſe only upon the market days, which are ſeldom oftener than once a week; ſo that unleſs a perſon has a garden of his own, there will be no ſuch thing as procuring them freſh, in which their goodneſs conſiſts; nor can any variety of theſe be had in the country markets; therefore whoever propoſes to reſide in the country, ſhould be careful to make choice of a proper ſpot of ground for this purpoſe; and the ſooner that is made and planted, the produce of it will be earlier in perfection; for fruit-trees and Aſparagus require three years to grow, before any produce can be expected from them; ſo that the later the garden is made, the longer it will be before a ſupply of theſe things can be had for the table. And although the uſefulneſs of this garden is acknowledged by almoſt every one, yet there are few who make a proper choice of ſoil and ſituation for ſuch a garden; the modern taſte, which is, perhaps, carried to as extravagant lengths, in laying open and throwing every obſtruction down, as the former cuſtom of incloſing within walls was ridiculous; ſo that now one frequently ſees the Kitchen-garden removed to a very great diſtance from the houſe and offices, which is attended with great inconveniencies; and often ſituated on a very bad ſoil, ſometimes too moiſt, and at others without water, ſo that there is a great expence in building walls and making the garden, where there can be little hopes of ſucceſs.

Nor will a Kitchen-garden be well attended to, when it is ſo ſituated as to be out of ſight of the poſſeſſor, eſpecially if the gardener has not a love and value for it, or if it lies at a great diſtance from his habitation, or the other parts of the garden; for when it ſo happens, a great part of the labourer's time will be loſt in going from one part to the other: therefore, before the general plan of the pleaſure-garden is ſettled, a proper piece of ground ſhould be choſen for this purpoſe, and the plan ſo adapted, as that the Kitchen-garden may not become offenſive to the ſight, which may be effected by proper plantations of ſhrubs to ſcreen the walls; and through theſe ſhrubs may be contrived ſome winding walks to lead to the Kitchen-garden, which will have as good an effect as thoſe which are now commonly made in gardens for pleaſure only. In the choice of the ſituation, if it does not obſtruct the view of better objects, or ſhut out any material proſpect, there can be no objection to the placing it at a reaſonable diſtance from the houſe or offices; for as particular things may be wanted for the kitchen, which were not thought of at the time when directions were given to the gardener what to bring in; ſo if the garden is ſituated at a great diſtance from the houſe, it will be found very inconvenient to ſend thither as often as things are wanting: therefore it ſhould be contrived as near the ſtables as poſſible, for the conveniency of carrying the dung thither; which, if at a great diſtance, will add to the expence of the garden.

As to the figure of the ground, that is of no great moment, ſince in the diſtribution of the quarters all irregularities may be hid; though if you are at full liberty, an exact ſquare or an oblong, is preferable to any other figure.

The great thing to be conſidered is, to make choice of a good ſoil, not too wet, nor over dry, but of a middling quality; nor ſhould it be too ſtrong or ſtubborn, but of a pliable nature, and eaſy to work; and if the place where you intend to make the Kitchen-garden ſhould not be level, but high in one part and low in another, I would by no means adviſe the levelling it; for by this ſituation you will have an advantage which could not be obtained on a perfect level, which is, the having one part dry ground for early crops, and the low part for late crops, whereby the kitchen may be the better ſupplied throughout the ſeaſon with the various ſorts of herbs, roots, &c. And in very dry ſeaſons, when in the upper part of the garden the crop will greatly ſuffer with drought, then the lower part will ſucceed, and ſo vice verſâ; but I would by no means direct the chuſing a very low moiſt ſpot of ground for this purpoſe; for although in ſuch ſoils garden-herbs are commonly more vigorous and large in the ſummer ſeaſon, yet they are ſeldom ſo well taſted or wholeſome as thoſe which grow upon a moderate ſoil; and eſpecially ſince in this garden your choice fruits ſhould be planted, it would be wrong to have a very wet ſoil.

This garden ſhould be fully expoſed to the ſun, and by no means overſhadowed with trees, buildings, &c. which are very injurious to your kitchen plants and fruit-trees; but if it be defended from the north wind by a diſtant plantation, it will greatly preſerve your early crops in the ſpring; as alſo from the ſtrong ſouth-weſt winds, which are very hurtful in autumn to fruit and garden-herbs. But theſe plantations ſhould not be too near nor very large; for I have generally found where Kitchen-gardens are placed near woods or large plantations, they have been much more troubled with blights in the ſpring, than thoſe which have been more expoſed.

The quantity of ground neceſſary for a Kitchen-garden muſt be proportioned to the largeneſs of the family, or the quantity of herbs deſired: for a ſmall family, one acre of ground may be ſufficient; but for a large family, there ſhould not be leſs than three or four acres; becauſe, when the ground is regularly laid out, and planted with eſpaliers of fruit-trees, as will hereafter be directed, this quantity will be found little enough, notwithſtanding what ſome perſons have ſaid on this head.

This ground muſt be walled round, and if it can be conveniently contrived, ſo as to plant both ſides of the walls which have good aſpects, it will be a great addition to the quantity of wall fruit; and thoſe ſlips of ground which are without ſide of the walls, will be very uſeful for planting of Gooſeberries, Currants, Strawberries, and ſome ſorts of kitchen plants, ſo that they may be rendered equally uſeful with any of the quarters within the walls; but theſe ſlips ſhould not be too narrow, leſt the hedge, pale, or plantation of ſhrubs, which incloſe them, ſhould ſhade the borders where the fruit-trees ſtand: the leaſt width of theſe ſlips ſhould be twenty-five or thirty feet, but if they are double that, it will be yet better, and the ſlips will be more uſeful, and the fruit-trees will have a larger ſcope of good ground for their roots to run. Theſe walls ſhould be built about twelve feet high, which will be a ſufficient height for any ſort of fruit.

If the ſoil where you intend to place your Kitchen-garden be very ſtrong, then you ſhould plough or dig it three or four times before you plant any thing therein; and if you throw it up in ridges to receive the froſt in winter, it will be of great ſervice to meliorate and looſen its parts.

The manure which is moſt proper for ſuch ſoils, is ſea-coal aſhes, and the cleanſing of ſtreets or ditches, which will render it light much ſooner than any other dung or manure; and the greater the quantity of aſhes the better, eſpecially if the ground be cold; and where theſe aſhes are not to be obtained in plenty, ſea-ſand is a very proper dreſſing, where it can be eaſily procured, or rotten wood, or the parts of vegetables rotted are very good; all which will greatly looſen the ſoil, and cauſe it to be not only eaſier to work, but alſo more advantageous for the growth of plants.

But, on the contrary, if your ſoil be light and warm, you ſhould manure it with rotten neats dung, which is much preferable to any other dreſſing for hot ſoils; but if you uſe horſe dung, it muſt be well rotted, otherwiſe it will burn up the crops upon the firſt hot dry weather.

The ſoil of this garden ſhould be at leaſt two feet deep, but if deeper it will be ſtill better, otherwiſe there will not be depth enough of ſoil for many ſorts of eſculent roots, as Carrots, Parſneps, Beets, &c. which run down pretty deep in the ground, and moſt other ſorts of eſculent plants delight in a deep ſoil; and many plants, whoſe roots appear ſhort, yet if their fibres by which they receive their nouriſhment are traced, they will be found to extend to a conſiderable depth in the ground; ſo that when theſe are ſtopped by meeting with gravel, chalk, clay, &c. the plants will ſoon ſhew it by their colour and ſtinted growth.

You ſhould alſo endeavour to have a ſupply of water in the different parts of the garden, which, if poſſible, ſhould be contained in large baſons or reſervoirs, where it may be expoſed to the open air and ſun, that it may be ſoftened thereby; for ſuch water as is taken out of wells, &c. juſt as it is uſed, is by no means proper for any ſort of plants.

In the diſtribution of this garden, after having built the walls, you ſhould lay out banks or borders under them, which ſhould be at leaſt eight or ten feet broad, whereby the roots of the fruit-trees will have greater liberty than in ſuch places where the borders are not above three or four feet wide; and upon theſe banks you may ſow many ſorts of early crops, if expoſed to the ſouth; and upon thoſe expoſed to the north, you may have ſome late crops; but I would by no means adviſe the planting any ſort of deep rooting plants too near the fruit-trees, eſpecially Peas and Beans; tho' for the advantage of the walls, to preſerve them in winter, and to bring them forward in the ſpring, the gardeners in general are too apt to make uſe of thoſe borders, which are near the beſt aſpected walls, to the great prejudice of their fruit-trees; but for theſe purpoſes it is much better to have ſome Reed-hedges fixed in ſome of the warmeſt quarters, under which you ſhould ſow and plant early Peas, Beans, &c. where they will thrive as well as if planted under a wall, and hereby your fruit-trees will be entirely freed from ſuch troubleſome plants.

Then you ſhould proceed to dividing the ground out into quarters, which muſt be proportioned to the largeneſs of the garden; but I would adviſe never to make them too ſmall, whereby your ground will be loſt in walks; and the quarters being incloſed by eſpaliers of fruit-trees the plants therein will draw up ſlender, and never arrive to half the ſize as they would do in a more open expoſure.

The walks of this garden ſhould be alſo proportioned to the ſize of the ground, which in a ſmall garden ſhould be four feet, but in a large one ſix; and on each ſide of the walk ſhould be allowed a border five or ſix feet wide between the eſpalier and the walk, whereby the diſtance between the eſpaliers will be greater, and the borders being kept conſtantly worked and manured, will be of great advantage to the roots of the trees; and in theſe borders may be ſown ſome ſmall ſallad, or any other herbs, which do not continue long or root deep, ſo that the ground will not be loſt.

The breadth of theſe middle walks which I have here aſſigned them, may by many perſons be thought too great; but my reaſon for this is to allow proper room between the eſpaliers, that they may not ſhade each other, or their roots interfere and rob each other of their nouriſhment: but where the walks are not required of this breadth, it is only enlarging of the borders on each ſide, and ſo reducing the walks to the breadth deſired.

But the walks of theſe gardens ſhould not be gravelled, for as there will conſtantly be occaſion to wheel manure, water, &c. upon them, they would ſoon be defaced, and rendered unſightly; nor ſhould they be laid with turf; for in green walks, when they are wheeled upon or much trodden, the turf is ſoon deſtroyed, and thoſe places where they are much uſed, become very unſightly alſo; therefore the beſt walks for a Kitchen-garden are thoſe which are laid with a binding ſand; but where the ſoil is ſtrong and apt to detain the wet, there ſhould be ſome narrow under ground drains made by the ſide of the walks, to carry off the wet, otherwiſe there will be no uſing of the walks in bad weather; and where the ground is very wet, and the water is detained by the ſtiffneſs of the ſoil, if ſome lime-rubbiſh, flints, chalk, or any ſuch material as can be procured with the leaſt expence, and is laid at the bottom of theſe walks; or if neither of theſe can be had, a bed of Heath or Furze ſhould be laid, and the coat of ſand laid over it; the ſand will be kept drier, and the walks will be found and good in all ſeaſons. Theſe ſand-walks when they are well laid, are by much the eaſieſt kept of any; for when either weeds or Moſs begin to grow, it is but ſcuffling them over with a Dutch hoe in dry weather, and raking them over a day or two after, and they will be as clean as when firſt laid.

The beſt figure for the quarters to be diſpoſed into, is a ſquare or an oblong, where the ground is adapted to ſuch a figure; otherwiſe they may be triangular, or of any other ſhape, which will be moſt advantageous to the ground.

When the garden is laid out in the ſhape intended, if the ſoil is ſtrong, and ſubject to detain the moiſture, or is naturally wet, there ſhould always be underground drains made, to carry off the wet from every quarter of the garden, for otherwiſe moſt ſorts of kitchen plants will ſuffer greatly by moiſture in winter; and if the roots of the fruit-trees get into the wet, they will never produce good fruit, ſo that there cannot be too much care taken to let off all ſuperflous moiſture from the Kitchen-garden.

Theſe quarters ſhould be conſtantly kept clear from weeds, and when any part of the ground is unoccupied, it ſhould always be trenched up into ridges, that it may ſweeten and imbibe the nitrous particles of the air, which is of great advantage to all ſorts of land, and the ground will then be ready to lay down whenever it is wanted.

The ground in theſe quarters ſhould not be ſown or planted with the ſame crop two years together, but the crops ſhould be annually changed, whereby they will prove much better than when they conſtantly grow upon the ſame ſpot. Indeed the kitchen-gardeners near London, where the land is dear, are often obliged to put the ſame crop upon the ground for two or three years together; but then they dig and manure their land ſo well every year, as to render it almoſt new; though notwithſtanding all this, it is conſtantly obſerved, that freſh land always produces the beſt crops.

In one of theſe quarters, which is ſituated neareſt to the ſtables, and beſt defended from the cold winds; or if either of the ſlips without the garden wall, which is well expoſed to the ſun, lies convenient, and is of a proper width, that ſhould be preferred for a place to make hot-beds for early Cucumbers, Melons, &c. The reaſons for my giving the preference to one of theſe ſlips, is, firſt, there will be no dirt or litter carried over the walks of the Kitchen-garden in winter and ſpring, when the weather is generally wet, ſo that the walks will be rendered unſightly; ſecondly, the view of the hot-beds will be excluded from ſight; and laſtly, the convenience of carrying the dung into theſe ſlips, for by making of a gate in the hedge, or pale, wide enough for a ſmall cart to enter, it may be done with much leſs trouble than that of barrowing it thro' the garden; and where there can be a ſlip long enough to contain a ſufficient number of beds for two or three years, it will be of great uſe; becauſe by the ſhifting of the beds annually, they will ſucceed much better than when they are continued for a number of years on the ſame ſpot of ground; and as it will be abſolutely neceſſary to fence this Melon-ground round with a Reed-hedge, it may be ſo contrived as to move away in pannels; and then that hedge which was on the upper ſide the firſt year, being carried down to a proper diſtance below that which was the lower hedge, and which may remain, there will be no occaſion to remove more than one of the croſs hedges in a year; therefore I am perſuaded, whoever will make trial of this method, will find it the moſt eligible.

The moſt important points of general culture conſiſt in well digging and manuring the ſoil, and giving a proper diſtance to each plant, according to their diffrent growths (which is conſtantly exhibited in their ſeveral articles in this book) as alſo in keeping them clear from weeds; for if weeds aae permitted to grow until their ſeeds are ripe, they will ſhed upon the ground, and fill it ſo as not to be gotten out again in ſeveral years. You ſhould alſo obſerve to keep your dunghills always clear from weeds, for it will be to litte purpoſe to keep the garden clean, if this is not obſerved; for the ſeeds falling among the dung, will be brought into the garden, whereby there will be a conſtant ſupply of weeds yearly introduced, to the no ſmall damage of your plants, and a perpetual labour occaſioned to extirpate them again. Another thing which is abſolutely neceſſary to be obſerved, is, to carry off all the refuſe leaves of Cabbages, the ſtalks of Beans and haulm of Peaſe, as ſoon as they are done with, for the ill ſcent which moſt people complain of in the Kitchen-gardens, is wholly occaſioned by theſe things being ſuffered to rot upon the ground; therefore when the Cabbages are cut, all leaves ſhould be carried out of the garden while they are freſh, at which time they may be very uſeful for feeding of hogs, or other animals, and this will always keep the garden neat and free from ill ſcents. As for all other neceſſary directions, they will be found in the articles of the ſeveral ſorts of kitchen plants, which renders it needleſs to be repeated in this place.

KLEINIA. See Cacalia.

KNAUTIA. Lin. Gen. Plant. 109. Lychni-Scabioſa. Boerh. Ind. I. 131.

This name was applied to this plant by Dr. Linnæus, in honour of the memory of Dr. Chriſtian Knaut, who publiſhed a method of claſſing plants.

The Characters are,

It hath a ſingle oblong empalement, containing ſeveral floſcular flowers, which are ranged ſo as to appear regular, but each irregular, having tubes the length of the empalement, but are cut at the brim into four irregular ſegments, the outer being the biggeſt; it hath four ſtamina the length of the tube, inſerted in the receptacle, terminated by oblong incumbent ſummits; and a germen under the petal, ſupporting a ſlender ſtyle, crowned by a thick bifid ſtigma, *which afterward becomes a four-cornered ſeed with a hairy apex.*

This genus of plants is ranged in the firſt ſection of Linnæus's fourth claſs, intitled Tetrandria Monogynia, the flowers having four ſtamina and one ſtyle.

The Species are,

1. Knautia (*Orientalis*) foliis omnibus pinnatifidis, corollis calyce longioribus. Lin. Sp. App. 1679. *Knautia with all the leaves wing-pointed, and the petal longer than the empalement.* Lychni-ſcabioſa, flore rubro, annua. Boerh. Ind. alt.
2. Knautia (*Propontica*) foliis ſuperioribus lanceolatis indiviſis, corollis calyce æqualibus. Lin. Sp. App. 1666. *Knautia whoſe upper leaves are ſpear-ſhaped and whole, and the petal of the flower equal to the empalement.* Scabioſa Orientalis villoſa, flore ſuaverubente, fructu pulchro oblongo. Tourn. Cor. 35.

Theſe plants are natives of the Eaſt, they are both annual; the firſt has been long cultivated in the Engliſh gardens; this riſes with an erect branching ſtalk four feet high, garniſhed with wing-pointed leaves; the branches are terminated by ſingle foot-ſtalks, each ſupporting one flower, having a tubular empalement cut into four ſegments at the top, and each contain four florets of a bright red colour, cut into four unequal ſegments, the outer being much larger than the other; theſe have four ſtamina the length of the tube of the petal, terminated by oblong ſummits; and the flowers are ſucceeded by oblong four-cornered ſeeds, which, when ripe, ſoon fall out of the cup if they are not gathered.

The ſecond ſort differs from the firſt in its upper leaves being whole, and the petal of the flower being equal to the cup. The lower leaves of this are ſawed on their edges, and terminate in acute points.

Theſe plants propagate eaſily; if their ſeeds are permitted to ſcatter in the autumn, the plants will come up ſoon after; and if ſome of theſe are planted in the borders of the pleaſure-garden, or among low ſhrubs near the walks in October, the plants will live through the winter, and flower in June; ſo their ſeeds will ripen the end of July or beginning of Auguſt, therefore require no other culture but to keep them clean from weeds.

KNIGHTS CROSS, or SCARLET CROSS, is the Scarlet Lychnis. See Lychnis.

L.

LABIATE FLOWERS are ſuch as have lips, or more properly a labiated flower, is an irregular monopetalous flower, divided into two lips; the upper is called the creſt, the under the beard; ſometimes the creſt is wanting, and then the ſtyle and chives ſupply its place, as in the Ground Pine, Scordium, Bugula, &c. but the greateſt part have two lips, which, in ſome ſpecies the upper lip is turned upwards, as the Ground Ivy, &c. but moſt uſually the upper lip is convex above, and turns the hollow part down to the lower lip, and ſo repreſents a kind of helmet, or monk's hood, from whence theſe are called galeate, cucullate, and galericulate flowers, in which form are moſt of the verticillate plants.

LABLAB. See Phaseolus.

LABRUM VENERIS. See Dipsacus.

LABRUSCA. See Vitis.

LABURNUM. See Cytisus.

LABYRINTH [Λαϐύρινθος,] a winding, mazy, and intricate turning to and fro, through a wilderneſs or a wood.

The deſign of a Labyrinth is, to cauſe an intricate and difficult labour to find out the center, and the aim is, to make the walks ſo intricate, that a perſon may loſe himſelf in them, and meet with as great a number of ſtops and diſappointments as is poſſible, they being the moſt valuable that are moſt intricate.

As to the contrivance of them, it will not be poſſible to give directions in words, there are ſeveral plans and deſigns in books of gardening; they are rarely met with but in great and noble gardens, as Hamptoncourt, &c.

There are two ways of making them, the firſt is with ſingle hedges; this method has been practiſed in England. Theſe, indeed, may be beſt, where there is but a ſmall ſpot of ground to be allowed for the making them, but where there is ground enough, the double are moſt eligible.

Double ones, or thoſe that are made with double hedges of a conſiderable thickneſs of wood between hedge and hedge, are approved as much better than ſingle ones, as is the manner of making them in France, and other places, of all which, that of Verſailles is allowed by all to be the nobleſt of its kind in the world.

It is an error in Labyrinths in making them too narrow, for by that means the hedges muſt be kept cloſe clipped; whereas, if the walks are made wider, according to the foreign practice, they will not ſtand in ſo much need of it.

The walks are made with gravel, and the hedges are uſually ſet with Hornbeams; the palliſades ought to be ten, twelve, or fourteen feet high; the Hornbeam ſhould be kept cut, and the walks rolled.

LACRYMA JOBI [ſo called, becauſe the ſeed of it reſembles a tear, or drop.] Job's Tears. See Coix.

LACTIFEROUS PLANTS are ſuch as abound with a milky juice, as the Euphorbia, Sonchus, Lactuca, &c.

LACTUCA. Tourn. Inſt. R. H. 473. tab. 267. Lin. Gen. Plant. 814. [ſo called from lac, *Lat.* milk, becauſe the leaves, ſtalks, flower, and branch, being broken, plentifully emit a milk, or white milky juice, quickly turning yellow and bitteriſh.] Lettuce; in French, *Laitue*.

The Characters are,

The flowers are compoſed of ſeveral hermaphrodite florets, incloſed in one ſcaly oblong empalement; theſe lie over each other like the ſcales of fiſh. The florets have one petal, which is ſtretched out on one ſide like a tongue, and is ſlightly indented at the end in three or four parts; theſe have each five ſhort hairy ſtamina; the oval germen ſup-

ports a ſlender ſtyle, crowned by two reflexed ſtigmas, and afterward becomes one oblong pointed ſeed, crowned with a ſingle down, ſitting in the ſcaly empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's nineteenth claſs, intitled Syngeneſia Polygamia æqualis, which includes thoſe plants whoſe flowers are compoſed of all hermaphrodite, or fruitful florets, and have their ſtamina and ſtyle connected.

It would be beſide my purpoſe to mention in this place the ſeveral ſorts of Lettuce that are to be found in botanic writers, many of which are plants of little uſe, and are never cultivated but in botanic gardens for variety; ſome of them are found wild in many parts of England. I ſhall therefore paſs over thoſe, and only mention the ſeveral varieties which are cultivated in the kitchen-garden for uſe: 1. Common or Garden Lettuce. 2. Cabbage Lettuce. 3. Cilicia Lettuce. 4. Dutch Brown Lettuce. 5. Aleppo Lettuce. 6. Imperial Lettuce. 7. Green Capuchin Lettuce. 8. Verſailles, or Upright White Cos Lettuce. 9. Black Cos. 10. Red Capuchin Lettuce. 11. Roman Lettuce. 12. Prince Lettuce. 13. Royal Lettuce. 14. Egyptian Cos Lettuce.

The firſt of theſe ſorts is commonly ſown for cutting very young, to mix with other ſmall ſallad herbs, and is only different from the ſecond ſort, in being a degeneracy therefrom, or otherwiſe the ſecond is an improvement by frequent cultivation from the firſt; for if the ſeeds are ſaved from ſuch plants of the ſecond ſort as did not cabbage cloſely, the plants produced from that ſeed will degenerate to the firſt ſort, which is by the gardeners called Lapped Lettuce, to diſtinguiſh it from the other, which they call Cabbage Lettuce. The ſeeds of the firſt, which are commonly ſaved from any of the plants, without having regard to their goodneſs, are generally ſold at a very cheap rate (eſpecially in dry ſeaſons, when theſe plants always produce the greateſt quantity of ſeeds,) though ſometimes this ſeed is ſold in the ſeed-ſhops, and by perſons who make a trade of ſelling ſeeds, for the Cabbage Lettuce, which is often the occaſion of peoples being diſappointed in their crop; ſo that this ſort ſhould never be cultivated but to be cut up very young, for which purpoſe this is the only good ſort, and may be ſown any time of the year, obſerving only in hot weather to ſow it in ſhady borders; and in the ſpring and autumn upon warm borders, but in winter it ſhould be ſown under glaſſes, otherwiſe it is ſubject to be deſtroyed by ſevere froſts.

The Cabbage Lettuce may alſo be ſown at different times of the year, in order to have a continuation of it through the whole ſeaſon. The firſt crop is generally ſown in February, which ſhould be upon a warm ſpot of ground, and when the plants are come up, they ſhould be thinned out to the diſtance of ten inches each way, which may be done by hoeing them out, as is practiſed for Turneps, Carrots, Onions, &c. provided you have no occaſion for the ſuperfluous plants, otherwiſe they may be drawn up, and tranſplanted into another ſpot of good ground at the ſame diſtance, which, if done before the plants are too large, they will ſucceed very well, though they will not be ſo large as thoſe which are left upon the ſpot where they were ſown, but they will come ſomewhat later, which will be of ſervice where people do not continue ſowing every fortnight or three weeks in ſummer.

You muſt alſo obſerve in ſowing the ſucceeding crops, as the ſeaſon advances, to chuſe a ſhady moiſt ſituation, but not under the drip of trees, otherwiſe, in the heat of ſummer they will run up to ſeed before they cabbage. In the beginning of Auguſt you ſhould ſow the laſt crop, which is to ſtand over winter; the ſeeds ſhould be ſown thin upon a good light ſoil, in a warm ſituation, and when the plants are come up they muſt be hoed out, ſo as they may ſtand ſingly, and cut down all the weeds to clear them. In the beginning of October they ſhould be tranſplanted into warm borders, where, if the winter is not very ſevere, they will ſtand very well; but in order to be ſure of a crop, it will be adviſeable to plant a few upon a bed pretty cloſe together, where they may be arched over with hoops, and in ſevere froſts they ſhould be covered with mats and ſtraw, or Peas-haulm, to ſecure them from being deſtroyed; and in the ſpring of the year they may be tranſplanted out into a warm rich ſoil, at the diſtance before-mentioned; but ſtill thoſe which grew under the wall, if they eſcaped the winter, and were ſuffered to remain, will cabbage ſooner than thoſe which are removed again; but you muſt obſerve not to place them too cloſe to the wall, which would occaſion their growing up tall, and prevent their being large or hard.

In order to ſave good ſeeds of this kind, you ſhould look over your Lettuces when they are in perfection, and ſuch of them as are very hard, and grow low, ſhould have ſticks thruſt into the ground, by the ſides of as many of them as you intend for ſeed, to mark them from the reſt; and you ſhould carefully pull up all the reſt from amongſt them as ſoon as they begin to run up, if any happen to be left, leſt when they are run up to flower, they ſhould, by the intermixing their farina with the good ones, degenerate the ſeeds. It may be ſome perſons may object, that ſuppoſe ſome bad ones ſhould happen to be left among them (for ſeeds to ſow for ſmall ſallads,) yet the good ones being marked, the ſeeds need not be mixed, and ſo no danger can enſue from thence; but notwithſtanding ever ſo much care be taken to keep the ſeeds ſeparate, yet, whether from the intermixing of the farina during the time of their being in flower, or what other cauſe, I cannot ſay, but it hath been frequently obſerved, that where good and bad plants have been left for ſeed upon the ſame ſpot, the ſeeds of the good plants which were carefully ſaved ſeparately, have very much degenerated, and proved worſe than ſuch as have ſeeded by themſelves. The ſeeds ſhould always be ſaved either from thoſe which ſtood through the winter, or thoſe which were ſown early in the ſpring, for the late ones very ſeldom perfect their ſeeds.

The Cilicia, Imperial, Royal, Black, White, and Upright Cos Lettuces may be ſown at the following times; the firſt ſeaſon for ſowing theſe ſeeds is at the latter end of February, or the beginning of March, upon a moderate hot-bed, or on a warm light ſoil in a ſheltered ſituation; and when the plants are come up and are fit to tranſplant, thoſe which were ſown on the hot-bed ſhould be planted on another warm bed about four inches aſunder, row from row, and two inches diſtance in the rows, obſerving to ſhade them from the ſun till they have taken new root; after which they ſhould have a larger ſhare of air admitted to them daily, to prevent their drawing up weak; but if the ſeaſon proves favourable, they ſhould be tranſplanted the beginning of April to the place where they are to remain, allowing them ſixteen inches room every way, for theſe large ſorts muſt not be planted too near each other; thoſe which were ſown in the full ground will be later before they come up, ſo ſhould be either hoed out, or tranſplanted into another ſpot of ground (as was directed for thoſe ſown on the hot-bed allowing them as much room) eſpecially if the ſoil be good; after they have taken new root, you muſt carefully keep them clear from weeds, which is the only culture they will require, except the Black Cos Lettuce, which ſhould be tied up when they are full grown (in the manner as was directed for blanching of Endive,) to whiten their inner leaves, and render them criſp, otherwiſe they are ſeldom good for much, rarely cabbaging without this aſſiſtance.

When your Lettuces are in perfection, you ſhould look over them, and mark as many of the beſt of them as you intend for ſeed (in the ſame manner as was before directed for the common Cabbage Lettuce,) being very careful not to ſuffer any ordinary ones to ſeed amongſt them, as was before obſerved, which would prove more injurious to theſe ſorts than to the common, as being more inclinable to degenerate with us, if they are not carefully ſaved.

You may alſo continue theſe ſorts through the whole ſeaſon of Lettuce, by ſowing them in April, May, and June, obſerving, (as was before directed) to ſow the late crops in a ſhady ſituation, otherwiſe they will run up to ſeed before they grow to any ſize; but in the middle of September you may ſow of theſe ſorts, to abide the winter; which plants ſhould be tranſplanted either under glaſſes, or into a bed, which ſhould be arched over with hoops, in order to be covered in the winter, otherwiſe in hard winters they are often deſtroyed; but you muſt conſtanly let theſe plants have as much free air as poſſible, when the weather is mild, only covering them in hard rains or froſty weather; for if they are kept too cloſely covered in winter, they will be ſubject to a mouldineſs, which ſoon rots them.

In the ſpring theſe plants ſhould be planted out into a rich light ſoil, allowing them at leaſt ſixteen inches diſtance each way; for if they are planted too cloſe, they are very ſubject to grow tall, but ſeldom cabbage well; and from this crop, if they ſucceed well, it will be proper to ſave your ſeeds; though you ſhould alſo ſave from that crop ſown on the hot-bed in the ſpring, becauſe ſometimes it happens, that the firſt may fail by a wet ſeaſon, when the plants are full in flower, and the ſecond crop may ſucceed, by having a more favourable ſeaſon afterwards; and if they ſhould both ſucceed, there will be no harm in that, ſince the ſeeds will grow very well when two years old, and if well ſaved, at three, but this will not always happen.

The moſt valuable of all the ſorts of Lettuce in England, are the Egyptian Green Cos, and the Verſailles, or White Coſs, and the Cilicia, though ſome people are very fond of the Royal and Imperial Lettuces, but they ſeldom ſell ſo well in the London markets as the other, nor are ſo generally eſteemed. Indeed of late years, ſince the White Cos has been commonly cultivated, it has obtained the preference of all the other ſorts, until the Egyptian Green Cos was introduced, which is ſo much ſweeter and tenderer than the White Cos, that it is by all good judges eſteemed the beſt ſort of Lettuce yet known. This ſort will endure the cold of our ordinary winters full as well as the White Cos; but at the ſeaſon of its cabbaging, if there happens to be much wet, this being very tender, is very ſubject to rot.

The Brown Dutch and Green Capuchin Lettuces are very hardy, and may be ſown at the ſame ſeaſons as was directed for the common Cabbage Lettuce, and are very proper to plant under a wall, or hedge, to ſtand the winter, where many times theſe will abide, when moſt of the other ſorts are deſtroyed, and therefore they will prove very acceptable at a time when few other ſorts are to be had; they will alſo endure more heat and drought than moſt other ſorts of Lettuce, which renders them very proper for late ſowing; for it very often happens, in very hot weather, that the other ſorts of Lettuce will run up to ſeed in a few days after they are cabbaged, whereas theſe will abide near a fortnight in good order, eſpecially if care be taken to cut the forwardeſt firſt, leaving thoſe that are not ſo hard cabbaged to be laſt. If ſome plants of theſe two laſt ſorts are planted under frames, on a moderate hot-bed in October, they will be fit for uſe in April, which will prove acceptable to thoſe who are lovers of Lettuce, and being covered by glaſſes, will render them tender. In ſaving of theſe ſeeds, the ſame care ſhould be taken to preſerve only ſuch as are very large and well cabbaged, otherwiſe the ſeeds will degenerate, and be good for little.

The Red Capuchin, Roman, and Prince Lettuces are pretty varieties, and cabbage very early, for which reaſon a few of them may be preſerved, as may alſo ſome of the Aleppo, for the beauty of its ſpotted leaves; though very few people care for either of theſe ſorts at table, when the other more valuable ones are to be obtained; but in a ſcarcity, theſe may ſupply the place pretty well, and theſe ſorts are very proper for ſoups. The ſeeds of theſe muſt alſo be ſaved from ſuch as cabbage beſt, otherwiſe they will degenerate, and be good for little.

In ſaving ſeeds of all theſe ſorts of Lettuce, you ſhould obſerve never to let two ſorts ſtand near each other, for by their farina mixing, they will both vary from their original, and partake of each other; and there ſhould be a ſtake fixed down by the ſide of each, to which the ſtem ſhould be faſtened, to prevent their being broken, or blown out of the ground by wind, to which the Cilicia, Cos, and the other large growing Lettuces, are very ſubject when they are in flower. You muſt alſo obſerve to cut ſuch branches of the large growing Lettuce as ripen firſt, and not wait to have the ſeed of the whole plant ripe together, which never happens; but, on the contrary, ſome branches will be ripe a fortnight or three weeks before others; and when you cut them, they muſt be ſpread upon a coarſe cloth in a dry place, that the ſeeds may dry, after which you ſhould beat them out, and dry them again, and then preſerve them for uſe, being careful to hang them up where mice and other vermin cannot come at them; for if they do, they will ſoon eat them up.

LACTUCA AGNINI. See VALERIANELLA.

LADY's SLIPPER. See CYPRIPEDIUM.

LADY's SMOCK. See CARDAMIN.

LAGŒCIA, Baſtard Cumin.

The CHARACTERS are,

It hath many flowers collected into a head, which have one common empalement, compoſed of eight indented leaves, but the ſimple empalement to each flower hath five leaves, which are very narrow and pinnated, ending in many hair-like points. The flower conſiſts of five horned petals, which are ſhorter than the empalement; at the bottom of each flower is ſituated the germen, ſupporting a ſtyle crowned by a ſimple ſtigma, attended by five ſtamina, which are long and narrow; the germen afterward changes to an oval ſeed, crowned with the empalement.

There is but one SPECIES of this plant, viz.

LAGOECIA (*Cuminoides.*) Lin. Hort. Cliff. *Baſtard, or Wild Cumin.*

We have no other Engliſh name for this plant, nor is this a very proper one, but as it has been titled by ſome of the antient botaniſts Cuminum ſylveſtre, i. e. Wild Cumin, and by Dr. Tournefort it is made a diſtinct genus, by the title of Cuminoides, it may be ſtyled Wild, or Baſtard Cumin.

This is an annual plant, which grows about a foot high. The leaves reſemble thoſe of the Honeywort. The flowers, which are of a greeniſh yellow colour, are collected in ſpherical heads at the extremity of the ſtalks; but there being little beauty in the plant, it is rarely cultivated, except in botanic gardens. It grows plentifully about Aix, in Provence, as alſo in moſt of the iſlands of the Archipelago. It is annual, and periſhes ſoon after the ſeeds are ripe. The ſeeds of this plant ſhould be ſown in autumn on a warm border, ſoon after they are ripe; or if they are permitted to ſcatter, the plants will come up, and require no other care but to clear them from weeds. When the ſeeds are ſown in the ſpring, they commonly remain in the ground a year before they grow, and ſometimes I have known them to lie two or three years in the ground, ſo that if the plants do not come up the firſt year, the ground ſhould not be diſturbed.

LAGOPUS. See TRIFOLIUM.

LAMINATED ſignifies platted. Thoſe things are ſaid to be laminated, whoſe contexture diſcovers ſuch a diſpoſition as that of plates lying over one another, or the ſcales of fiſh.

LAMIUM. Tourn. Inſt. R. H. 183. tab. 89. Lin. Gen. Plant. 636. Dead Nettle, or Archangel.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, which is tubulous, and cut into five equal ſegments at the top, which end in beards. The flower is of the lip kind; it hath one petal, with a ſhort cylindrical tube, ſwollen at the chaps and compreſſed; the upper lip is arched, roundiſh, obtuſe, and entire; the under is ſhort, heart-ſhaped, reflexed, and indented at the end. It hath four awl-ſhaped *ſtamina joined to the upper lip, two of which are longer than the other, terminated by oblong hairy ſummits. It hath a four-cornered germen, ſupporting a ſlender ſtyle ſituated with the ſtamina, and crowned by an acute two-pointed ſtigma; the germen afterward become four three-cornered ſeeds, ſitting in the open empalement.*

This genus of plants is ranged in the firſt ſection of Linnæus's fourteenth claſs, intitled Didynamia Gymnoſpermia, in which he ranges thoſe plants whoſe flowers have two long and two ſhorter ſtamina, and are ſucceeded by naked ſeeds ſitting in the empalement.

The Species are,

1. Lamium (*Purpureum*) foliis cordatis obtuſis petiolatis. Hort. Cliff. 314. *Dead Nettle with heart-ſhaped obtuſe leaves ſtanding on foot-ſtalks.* Lamium purpureum fœtidum, folio ſubrotundo, ſive Galeopſis Dioſcoridis. C. B. P. *Purple ſtinking Archangel, or Dead Nettle, or the Galeopſis of Dioſcorides with a roundiſh leaf.*
2. Lamium (*Album*) foliis cordatis acuminatis ſerratis petiolatis. Hort. Cliff. 314. *Dead Nettle with pointed heart-ſhaped leaves, which are ſawed, and have foot-ſtalks.* Lamium album, non fœtens, folio oblongo. C. B. P. *White Archangel or Dead Nettle which does not ſtink, with an oblong leaf.*
3. Lamium (*Garganicum*) foliis cordatis pubeſcentibus, corollis fauce inflata, tubo recto dente utrinque gemino. Lin. Sp. 808. *Dead Nettle with heart-ſhaped hairy leaves, and the chaps of the flower inflated, indented with two teeth.* Lamium garganicum ſubincanum, flore purpuraſcente, cum labio ſuperiore crenato. Micheli. *Hoary Dead Nettle with a purpliſh flower, whoſe upper lip is crenated.*
4. Lamium (*Moſchatum*) foliis cordatis obtuſis glabris, floralibus ſeſſilibus, calycibus profundè inciſis. *Dead Nettle with heart-ſhaped, obtuſe, ſmooth leaves, the upper ſitting cloſe to the ſtalks, and empalements deeply cut.* Lamium Orientale, nunc moſchatum, nunc fœtidum, magno flore. Tourn. Cor. *Eaſtern Dead Nettle, ſometimes ſweet-ſcented and ſometimes ſtinking, with a large flower.*
5. Lamium (*Meliſſæfolium*) foliis cordatis nervoſis ſerratis, petiolis longioribus, caule erecto. *Dead Nettle with heart-ſhaped veined leaves which are ſawed, and longer foot-ſtalks with an erect ſtalk.* Lamium montanum meliſſæ folio. C. B. P. 231. Icon. Pl. 158. *Mountain Dead Nettle with a Balm leaf.*

There are ſeveral other ſpecies of this genus, as alſo ſome varieties of it, but as moſt of them are weeds, I have paſſed them over, for there are few who care to admit them into their gardens.

The firſt ſort grows naturally in moſt parts of England, under hedges and by the ſide of highways; it is alſo a troubleſome weed in gardens, but as it ſtands in moſt of the diſpenſaries as a medicinal plant, I have choſen to inſert it. This is an annual plant, whoſe ſtalks ſeldom riſe more than four or five inches high; the under leaves are heart-ſhaped, blunt, and ſtand upon pretty long foot-ſtalks, but the upper leaves ſit nearer to the ſtalks; the flowers come out in whorls on the upper part of the ſtalk; they are of a pale purple colour, and are ſucceeded by four naked ſeeds ſitting in the empalement; after the ſeeds are ripe the plant decays. It flowers in the middle of March, when the autumnal ſelf-ſown plants appear; theſe are ſucceeded by others, which continue in ſucceſſion all the ſummer.

The ſecond ſort is commonly called Archangel; this is alſo uſed in medicine, for which reaſon I have enumerated it here. The roots of this are perennial, and creep much in the ground, ſo is difficult to extirpate, where it happens to grow under buſhes and hedges; for the roots intermix with thoſe of the buſhes, and every ſmall piece of them grow and ſpread. The ſtalks of this riſe much higher than thoſe of the laſt, the flowers are larger, white, and grow in whorls round the ſtalks; theſe continue in ſucceſſion moſt part of the ſummer.

The third ſort grows naturally upon the mountains in Italy; this hath a perennial creeping root, from which ariſe many thick ſquare ſtalks a foot high, garniſhed with heart-ſhaped leaves which are hairy, placed oppoſite, ſtanding upon pretty long foot-ſtalks; the flowers come out in whorls at the upper joints of the ſtalk, they are large, and of a pale purpliſh colour; theſe continue in ſucceſſion moſt part of the ſummer, and the flowers are ſucceeded by ſeeds which ripen about ſix weeks after. This may be propagated by ſeeds, but as the roots ſpread greatly in the ground, ſo when once it is obtained, it will propagate faſt enough without culture.

The fourth ſort grows naturally in the Archipelago; this is an annual plant, which, if permitted to ſcatter its ſeeds, the plants will come up and thrive better than when ſown by the hand. The plants come up in the autumn, and during the winter their leaves make a pretty appearance, for they are marked with white ſomewhat like thoſe of the autumnal Cyclamen; the ſtalks riſe eight or nine inches high, and are garniſhed with ſmooth heart-ſhaped leaves placed oppoſite; theſe in dry weather have a muſky ſcent, but in wet weather are fetid; the flowers are white, ſtanding in whorls round the ſtalks. They appear in April, and the ſeeds ripen in June, then the plants decay; this requires no culture, but to keep the plants clear from weeds.

The fifth ſort grows naturally in Portugal; this hath a perennial root and an annual ſtalk, which riſes a foot and a half high; it is ſtrong, ſquare, and grows erect; the leaves are large, heart-ſhaped, and much veined; they are deeply ſawed on their edges, and are placed oppoſite. The flowers come out in whorls round the ſtalks at every joint; they are very large, and of a deep purple colour; thoſe on the lower part of the ſtalks appear the beginning of May, which are ſucceeded by others above, ſo that there is a continuance of flowers almoſt two months on the ſame ſtalks. This plant very rarely produces good ſeeds in England, nor do the roots propagate very faſt, ſo that it is not common here.

The beſt time to remove and part theſe roots is in October, but they muſt not be tranſplanted oftener than every third year if they are required to flower ſtrongly; for the great beauty of this plant conſiſts in the number of ſtalks, which are always proportional to the ſize of the plants; for ſmall plants will put out one or two ſtalks only, whereas the larger ones will have eight or ten. The roots are hardy, and will thrive beſt in a ſoft loamy ſoil.

LAMPSANA. See Lapsana.

LAND. Its improvement.

1. By incloſing.

Incloſing of Lands, and dividing the ſame into ſeveral fields, for paſture or tillage, is one of the principal ways of improvement; firſt, by aſcertaining to every man his juſt property, and thereby preventing an infinity of treſpaſſes and injuries, that Lands in common are ſubject unto, beſide the diſadvantage of being obliged to keep the ſame ſeaſons with the other people who have Land in the ſame field; ſo that the ſowing, fallowing, and tilling the ground, muſt be equally performed by all the landholders; and when there happens a ſlothful negligent perſon, who has Land intermixed with others, it is one of the greateſt nuiſances imaginable. Secondly, it being of itſelf a very great improvement; for where Land is properly incloſed, eſpecially in open countries, and the hedge-rows planted with timber trees, &c. it preſerves the Land warm, and defends and ſhelters it from the violent cold nipping winds, which, in ſevere winters, deſtroy much of the corn, pulſe, or whatever grows on the open field or champain grounds. And where it is laid down for paſture, it yields much more Graſs than the open fields, and the Graſs will begin to grow much ſooner in the ſpring. The hedges and trees will afford ſhelter for the cattle from the cold winds in winter, as alſo ſhade for them in the great heats of ſummer. And theſe hedges afford the diligent huſbandman plenty of fuel, as plough-boot, cart-boot, &c. And where they are carefully planted and preſerved, furniſh him with timber and alſo maſt for his ſwine; or where the hedge-rows are planted with fruit-trees, there will be a ſupply of fruit for cyder, perry, &c. which in moſt parts of England are of no ſmall advantage to the huſbandman.

By this method of incloſing, there is alſo much more employment for the poor, and is therefore a good remedy againſt beggary; for in thoſe open countries, where there are great downs, commons, heaths, and waſtes, there is nothing but poverty and idleneſs to be ſeen amongſt the generality of their inhabitants. It is very obſervable of late years, how much advantage the incloſing of the Land in Worceſterſhire, and ſome other counties at a diſtance from London, has been to the inhabitants: for before this method was introduced amongſt them, the Lands for the moſt part lay in commons, &c. Upon which the poorer ſort of people built themſelves cottages with mud walls, where they contented themſelves with a cow or two, and ſome ſwine; and thoſe of them who were more induſtrious than the reſt, travelled to the neighbourhood of London every ſpring, where they were employed in the gardens and fields for the ſummer ſeaſon; and in autumn they returned to their native countries, where they lived in winter upon what money they had ſaved in ſummer. But ſince they have converted their waſtes and commons into incloſures, there are but few of the inhabitants of thoſe countries, who come to London for work, in compariſon to the numbers that formerly came; ſo that moſt of the labourers, who come to London for employment, are either Welch, or inhabitants of ſome more diſtant counties, or from Ireland, where this improvement hath not as yet been introduced.

The advantages of incloſing Land are now ſo generally known, that there is no occaſion for me to enumerate them here; ſince the improvements which have been made of late years in ſeveral parts of England, and the increaſe of rent that is every where made by thoſe who incloſe, are ſufficient arguments to enforce the practice, and render it general; more eſpecially in the north, where it is moſt neglected, becauſe it would greatly ſhelter the Lands, and render them much warmer than they now are.

In incloſing of Land, regard ſhould be had to the nature of the ſoil, and what it is intended for, becauſe Corn Land ſhould not be divided into ſmall parcels; for beſides the loſs of ground in hedges, &c. the Corn doth ſeldom thrive ſo well in ſmall incloſures, as in more open fields, eſpecially where the trees are large in the hedge-rows. The Graſs alſo in paſtures is not ſo ſweet near hedges, or under the drip of trees, as in an open expoſure; ſo that where the incloſures are made too ſmall, or the Land overplanted with trees, the herbage will not be near ſo good, nor in ſo great plenty, as in larger fields; therefore, before a perſon begins to incloſe, he ſhould well conſider how he may do it to the greateſt advantage; as for inſtance, it is always neceſſary to have ſome ſmaller incloſures near the habitation, for the ſhelter of cattle, and the conveniency of ſhifting them from one field to another, as the ſeaſon of the year may require; and hereby the habitation, barns, ſtables, and outhouſes, will be better defended from ſtrong winds, which often do great damage to thoſe that are expoſed to their fury. Theſe ſmall incloſures may be of ſeveral dimenſions, ſome of them three, four, ſix, or eight acres in extent; but the larger diviſions for Corn ſhould not contain leſs than twenty or thirty acres or more, according to the ſize of the farm, or the ſituation of it.

The uſual method of incloſing Land is, with a ditch and bank ſet with quick. But in marſh Land, where there is plenty of water, they content themſelves with only a ditch, by the ſides of which they uſually plant Sallows or Poplars, which being of quick growth, in a few years afford ſhade to the cattle; and when they are lopped, produce a conſiderable profit to their owners. In ſome counties the diviſion of their Lands is by dry walls made of flat ſtones, laid regularly one upon another, and laying the top courſe of ſtones in clay, to keep them together, the weight of which ſecures the under ones. But in ſome parts of Suſſex and Hampſhire, they often lay the foundation of their banks with flat ſtones, which is of a conſiderable breadth at bottom; upon which they raiſe the bank of earth, and plant the hedge on the top, which in a few years makes a ſtrong durable fence, eſpecially if they are planted with Holly, as ſome of thoſe in Suſſex are.

In marſhes and open paſtures, where there are no hedges, the ditches are generally made ſix feet wide at the top, eſpecially thoſe which are on the ſide of highways or commons; but the common ditches about incloſures are ſeldom more than three feet and a half wide at top, and one foot and a half at bottom, and two feet deep, that the ſides may have a good ſlope, and not be too upright, as they are frequently made about London, ſo that they are continually waſhing down with great rains. In theſe narrow bottomed ditches, the cattle cannot ſtand to turn themſelves, ſo as to crop the quick; but where the ditches are made wider, they ſhould be proportionally deeper: as for inſtance, if the ditch is made five feet broad, it muſt be three feet deep; and if ſix feet broad, three feet and a half deep, and ſo in proportion.

The method of incloſing Lands, by raiſing high banks of earth, on the ſide of which the quick is planted (as is too much practiſed in many places near London) is intolerable, for it is not only unſightly, but very expenſive; becauſe theſe banks are continually waſhing down, ſo that they muſt be repaired every year at leaſt, if not oftener, otherwiſe the earth will be in a few years waſhed from the roots of the quick, and for want of proper nouriſhment, the hedge will ſoon decay, which is the caſe with the greateſt number of the hedges about London: beſides, it is a very uncertain way of planting quick on the ſide of a ſteep bank, where all the moiſture runs off; ſo that if the ſpring ſhould prove dry after it is planted, there is a great hazard whether half the plants will grow, and thoſe that take ſeldom make much progreſs; whereas thoſe planted on the plain ſurface, where they enjoy the advantages of ſun and moiſture, will in four years make a better fence than one of theſe bank hedges will in eight or ten, and will continue good much longer than the other. Therefore I adviſe, that the banks on which the hedges are to be planted, ſhould not be raiſed more than one foot above the ſurface of the ground, where the Land is dry, and in wet Land not more than two feet, which will be enough.

I ſhall now mention the moſt proper plants for making of fences for the different ſoils and ſituations, ſo as to anſwer the expectation of the planter: and firſt, the white Thorn is eſteemed the beſt for fencing, and will grow upon almoſt any ſoil and in any ſituation, but it ſucceeds beſt on a hazle loam. Of this there are three or four varieties, which differ in the breadth of their leaves and the ſize of their Haws, but that ſort with the ſmalleſt leaves and Haws will make the cloſeſt fence. For it is very certain, that the branches of all ſorts of trees are produced at a diſtance, in proportion to the ſize of their leaves; ſo that Yews, and other Evergreen trees with ſmall leaves, will always make a cloſer hedge than other trees whoſe leaves are larger. Therefore, for the cloſeſt hedge, the ſmalleſt Haws ſhould be choſen; but where the moſt vigorous ſhooters are required, for the advantage of lopping, there the largeſt Haws ſhould be preferred. But as theſe hedges are uſually planted from a nurſery, where the Haws are promiſcuouſly ſown, it is very common to ſee two or three ſorts planted in the ſame hedge; which may be eaſily diſtinguiſhed, when they have obtained ſtrength, by the difference of their growth. Indeed, where a perſon is curious in raiſing of his own quick, it is worth while to gather the Haws ſeparately, and ſow them apart; and each ſort ſhould be planted in a ſeparate hedge, which will render the hedges more equal in their growth. If theſe Haws are ſown in the places where they are deſigned to remain for a fence, they will make a much greater progreſs in a few years, than thoſe which are tranſplanted; but as the ſeeds remain a whole year in the ground before the plants appear, few people care to practiſe this method; however, thoſe who are deſirous to raiſe their hedges this way, ſhould bury the Haws, by putting them in pots ſoon after they are ripe, and burying the pots two feet deep in the ground, where they may remain one year, then take them up and ſow them; by this preparation the plants will come up the following ſpring; but before they are ſown, the Haws ſhould be bruiſed with hands, and their outer coverings waſhed off, whereby the ſeeds may be ſown at a more regular diſtance; for as moſt of the Haws incloſe four or five ſeeds, ſo if they are ſown entire there will be as many plants ariſe in a cluſter, which if permitted to ſtand, will prevent each other's growth; and in drawing out the ſuperfluous plants, there will be great danger of injuring thoſe which are to remain.

The next to the white Thorn is the black Thorn, which, though not ſo generally eſteemed as the white, yet it will make an excellent fence, where proper care is taken in the planting and after management of it; and the loppings of this hedge make much the beſt buſhes for draining of Land, and are of longer duration for dead hedges than thoſe of any other ſort of tree, and are very proper to mend gaps in fences; for their branches being beſet with ſharp thorns, the cattle are not ſo apt to crop them as the white Thorn, and ſome other ſorts. Theſe hedges are alſo better, if the ſtones of the Plumbs are ſown on the ſpot where they are to remain, than where the plants are taken from a nurſery; if theſe are ſown in the autumn ſoon after the fruit is ripe, the plants will come up the ſpring following.

The Crab will alſo make a ſtrong durable fence; this may be raiſed by ſowing the kernels in the place where the hedge is deſigned; but then there ſhould be great care taken of the plants while they are young, to keep them clear from weeds, as alſo to guard them from cattle. When theſe ſtocks have obtained ſtrength, ſome of them may be grafted with Apples for cyder, where the fence is not expoſed to a public road; but theſe grafts ſhould not be nearer than thirty-five or forty feet, leſt they ſpoil the hedge, by their heads overgrowing and dripping on it.

The Holly is alſo an excellent plant for evergreen hedges, and would claim the preference to either of the former, were it not for the ſlowneſs of its growth while young, and the difficulty of tranſplanting the plants when grown to a moderate ſize. This will grow beſt in cold ſtony Lands, where, if once it takes well, the hedges may be rendered ſo cloſe and thick, as to keep out all ſorts of animals, and will grow to a conſiderable height, and is of long duration. Theſe hedges may be raiſed, by ſowing the berries, either in the place where they are deſigned to remain, or by planting young plants of three or four years growth; but as the berries continue in the ground an entire year before the plants appear, few perſons care to wait ſo long; therefore the uſual method is, to plant the hedges with plants of the before-mentioned age. But where this is practiſed, they ſhould be tranſplanted, either early in the autumn, or deferred till toward the end of March; then the ſurface of the ground ſhould be covered with mulch near their roots after they are planted, to keep the earth moiſt; and if the ſeaſon ſhould prove dry, the plants ſhould be watered at leaſt once a week, until they have taken root, otherwiſe they will be in danger of miſcarrying; for which reaſon the autumnal planting is generally preferred to the ſpring, eſpecially in dry grounds.

The Alder will alſo make a good hedge, when planted on a moiſt ſoil, or on the ſide of rivers, or large ditches; and will preſerve the bank from being waſhed away, where there are running ſtreams; for they ſpread pretty much at bottom, and ſend forth ſuckers from their roots in great plenty; but theſe hedges ſhould be ſheared at leaſt once a year, in order to make them thick. Theſe Alder hedges are very ornamental, when they are well kept in large gardens; and as they will thrive beſt on wet ſwampy Lands, where many other plants will not live, they ſhould be ſelected for ſuch ſituations.

Of late years the Furz has been much propagated for hedges in ſeveral parts of England, and indeed will make a good fence on poor, ſandy, or gravelly ſoils, where few other plants will grow. The beſt method of raiſing theſe hedges is, to ſow the ſeed about the latter end of March, or the beginning of April, in the place where the hedge is deſigned; for the plants will not bear to be tranſplanted, unleſs it be done while they are young, and then there is great hazard of their taking. The ground where the ſeeds are to be ſown ſhould be well cleanſed of weeds, and the ſurface made light; then there ſhould be two or three drills made (according to the width which the hedge is intended) about half an inch deep, into which the ſeeds ſhould be ſcattered pretty thick; and then the drills ſhould be filled up with the head of a rake, to cover the ſeeds. This work ſhould be performed in dry weather, for if much wet falls ſoon after the ſeeds are ſown, it is apt to burſt them. When the plants are come up, they ſhould be kept clear from weeds, that they may ſpread and grow thick at bottom; and if theſe hedges are ſecured from cattle brouſing on them, and are cut every ſpring juſt before they begin to ſhoot, they will make an exceeding cloſe fence; but where they are deſigned to be cut for fuel, then the beſt way is to let them ſpread in width; and when they are two years old, to cut them down in the ſpring, juſt before they begin to ſhoot, within two or three inches of the ground, which will cauſe them to ſend forth a number of ſhoots from each root, and thereby increaſe the width of the hedge; and by ſo doing, the plants will not run up tall and weak, and be in danger of being weighed down by great falls of ſnow. Theſe hedges when they are well grown, may be cut down every third or fourth year for fuel; wherefore if there is a treble row of Furz ſown, at about three feet apart, they may be cut down alternately, ſo that there will be a fence always remaining. But this is only recommended for ſuch ſandy Lands as lett for a ſmall rent, and where fuel is ſcarce. The beſt ſort of Furz for this purpoſe is the greater kind, commonly called the French Furz, which will grow to eight or ten feet high, and is not apt to ſpread ſo much as the ordinary ſmall ſort.

Elder is ſometimes planted for hedges, being very quick of growth; ſo that if ſticks or truncheons about four or five feet long be thruſt into a bank ſlopewiſe each way, ſo as to croſs each other, and thereby form a ſort of chequer work, it will make a fence for ſhelter in one year. But as this is a vigorous growing plant, it will never form a cloſe fence; and the young ſhoots being very ſoft and pithy, are ſoon broken by cattle or boys in their ſport. Beſides, where they are ſuffered to bear berries, and theſe are ſcattered over the neighbouring Land, they will come up the following ſpring, and become very troubleſome. Where theſe hedges are planted, they may be cut down every third year near the ground; and theſe ſtakes (when diveſted of their bark, ſo as to prevent their growing) will laſt longer in the ground, to ſupport Vines or any other plants, which do not require tall ſtakes, than any other ſort of tree yet known. And where the trees are ſuffered to grow to any conſiderable ſize, the wood is as hard as Box, and therefore very uſeful for turners and inſtrument makers. The beſt ſeaſon for planting theſe truncheons is ſoon after Michaelmas, becauſe the plants ſhoot very early in the ſpring. Of late years there have been many hedges, and other plantations, made of the white berried Elder, for the ſake of their fruit to make wine; which, if rightly made, hath the flavour of Frontiniac wine, and is by ſome perſons mixed with white wines, and vended for it.

There are ſome other plants which have been recommended for fences, but thoſe here enumerated are the moſt uſeful ſorts for ſuch purpoſes; wherefore I ſhall paſs over the others, as not worthy of the care of the huſbandman. And as to the farther directions for planting and preſerving of hedges, with inſtructions for plaſhing or laying them, the reader is deſired to turn to the articles of FENCES and HEDGES, where there are particular directions for theſe works exhibited, which I ſhall not here repeat.

The draining of Land is alſo another great improvement to it; for though meadows and paſtures, which are capable of being overflowed, produce a greater quantity of herbage than dry Land, yet where the wet lies too long upon the ground, the Graſs will be ſour and extremely coarſe; and where there is not care taken in time to drain this Land, it will produce little Graſs, and ſoon be overun with Ruſhes and Flags, ſo as to be of ſmall value. The land which is moſt liable to this, is cold ſtiff clays where the water cannot penetrate, but is contained as in a diſh; ſo that the wet which it receives in winter, continues till the heat of the ſun exhales the greateſt part of it.

The beſt method for draining of theſe Lands is, to cut ſeveral drains acroſs the Land, in thoſe places where the water is ſubject to lodge; and from theſe croſs drains to make a convenient number of other drains, to carry off the water to either ponds or rivers in the lower parts of the Land. Theſe drains need not be made very large, unleſs the ground be very low, and ſo ſituated as not to be near any river to which the water may be conveyed; in which caſe there ſhould be large ditches dug at proper diſtances, in the loweſt part of the ground, to contain the water; and the earth which comes out of the ditches ſhould be equally ſpread on the Land, to raiſe the ſurface. But where the water can be conveniently carried off, the beſt method is, to make under ground drains at proper diſtances, which may empty themſelves into large ditches, which are deſigned to carry off the water. Theſe ſort of drains are the moſt convenient, and as they are hid from the ſight do not incommode the Land, nor is there any ground loſt where theſe are made.

The uſual method of making theſe drains, is to dig trenches, and fill the bottoms with ſtones, bricks, Ruſhes, or buſhes, which are covered over with the earth which was dug out of the trenches; but this is not the beſt method, becauſe the water has not a free paſſage through theſe drains, ſo that whenever there is a flood, theſe drains are often ſtopped by the ſoil which the water frequently brings down with it.

The beſt method I have yet obſerved to make theſe drains, is to dig trenches to a proper depth for carrying off the water, which for the principal drains ſhould be three feet wide at their top, and ſloped down for two feet and a half depth, where there ſhould be a ſmall ledge or bank left on each ſide, upon which the croſs ſtakes or bearers ſhould be laid, and below theſe banks there ſhould be an open drain left, at leaſt one foot deep, and ten or eleven inches wide, that there may be room for the water to paſs through. Theſe larger drains ſhould be at convenient diſtances, and ſmaller drains of about ſeven or eight inches wide at top, and the hollow under the buſhes eight or nine inches deep, ſhould be cut acroſs the ground, which ſhould diſcharge the water into theſe larger drains. The number and ſituation of them muſt be in proportion to the wetneſs of the Land; and the depth of the earth above the buſhes, muſt alſo be proportioned to the intended uſe of the Land; for if it is arable Land to be ploughed, it muſt not be ſhallower than fourteen inches, that there may be ſufficient depth for the plough, without diſturbing the buſhes; but for paſture Land, one foot deep will be full enough; for when the buſhes lie too deep in ſtrong Land, they will have little effect, the ground above will bind ſo hard as to detain the wet on the ſurface.

When the drains are dug, there ſhould be prepared a quantity of good bruſh wood, the larger ſticks ſhould be cut out to pieces of about ſixteen or eighteen inches in length, which ſhould be laid acroſs upon the two ſide banks of the drain, at about four inches diſtance; then cover theſe ſticks with the ſmaller bruſh wood, Furz, Broom, Heath, or any other kind of bruſh, laying it lengthwiſe pretty cloſe; on the top of theſe may be laid Ruſhes, Flags, &c. and then the earth laid on to cover the whole. Theſe ſort of drains will continue good for a great number of years, and are never liable to the inconveniencies of the other, for the water will find an eaſy paſſage through them; and where there is plenty of bruſh wood, they are made at an eaſy expence; but in places where wood is ſcarce, it would be chargeable to make them: however, in this caſe, it would be a great advantage to theſe Lands, to plant a ſufficient number of cuttings of Willow, or the black Poplar, on ſome of the moiſt places, which would furniſh bruſh wood for theſe purpoſes in four or five years; and as the expence of planting theſe cuttings is trifling, there cannot be a greater advantage to an eſtate which wants draining, than to practiſe this method, which is in every perſon's power, ſince there is little expence attending it.

In countries where there is plenty of ſtone, that is the beſt material for making theſe under ground drains; for when theſe are properly made, they will never want repairing.

The beſt time of the year for making theſe drains is about Michaelmas, before the heavy rains of autumn fall, becauſe at this ſeaſon the Land is uſually dry, ſo that the drains may be dug to a proper depth; for when the ground is wet, it will be very difficult to dig to any depth, becauſe the water will drain in wherever there is an opening in the ground.

When theſe drains are made, and the water carried off the Land, it will be proper to pare off the Ruſhes, Flags, &c. which may be laid in heaps in proper places to rot, and will afford a good manure for the land. The ground muſt alſo be ploughed to deſtroy the roots of noxious weeds, and if it be laid fallow for one ſeaſon, and ploughed two or three times, it will greatly mend the Land. The Ruſhes and Flags which were pared off the ground when rotten, ſhould be ſpread over the ſurface, and the Graſs-ſeed ſown thereon, which will greatly forward the Graſs, ſo that it may ſoon be brought to a good turf; which Land thus mended, has been lett for four times the rent it was ſet at before.

There are ſome perſons, who, after they have pared off the Flags, Ruſhes, &c. from their Land, lay them in ſmall heaps, and burn them in dry weather, then ſpread the aſhes on the Land to improve it, which is a good method, where a perſon is in haſte to have Graſs again; but where the ground can be fallowed one year, it will looſen the ſoil, and more effectually deſtroy the roots of all noxious weeds; and the Ruſhes, &c. when rotted, will afford a much larger quantity of manure for the Land than when it is burnt: beſides, this can only be practiſed in the ſummer ſeaſon, when the weather is very dry; for if there ſhould fall much rain, the fires will go out, and it will be impracticable to burn it. But where the method of burning is practiſed, the heaps ſhould not be too great, and it ſhould burn very ſlowly; which will render the aſhes a much better manure, than when the fire is too violent, or the heaps too large; for in this caſe, the inner part will be over-burnt before the fire reaches the outſide of the heap.

As the draining of cold wet Lands is a great improvement to them, ſo the floating or watering of dry looſe Land is not a leſs advantage to them. This may be eaſily effected where there are rivers, or reſervoirs of water, which are ſituated above the level of the ground deſigned to be floated, by under ground drains (made after the manner of thoſe before directed for draining of Land,) through which the water may be conveyed at proper ſeaſons, and let out on the ground: in order to this, there muſt be good ſluices made at the heads of the drains, ſo that the water may never get out, but at ſuch times as is required;

for if this be not taken care of, the water, inſtead of improving the Land, will greatly damage it.

But where the Land lies ſo high, as that there is no water in the neighbourhood lying above its level, it will be more expenſive; becauſe in ſuch caſe, the water muſt be raiſed by machines, from reſervoirs or ſtreams which lie below it. The moſt common engine uſed for this purpoſe is the Perſian wheel (which, being well deſcribed and figured in Woolridge's Art of Huſbandry, is needleſs for me here to repeat.) Yet notwithſtanding the expence of raiſing the water, it has been found greatly advantageous in many parts of England, to drown the Lands, for the profit has many times more than doubled the charge.

The time for drowning of Land, is uſually from November till the end of April; but though this is the general practice, yet I cannot approve of it for many reaſons. The firſt is, that by the wet lying continually on the ground in winter, the roots of the finer ſort of Graſs are rotted and deſtroyed; and by letting on the water, at the ſeaſon when the ſeeds of Docks, and other bad weeds, which commonly grow by river ſides, are falling, theſe ſeeds are carried upon the Land, where they remain and grow, and fill the ground with bad weeds, which is commonly the caſe with moſt of the water meadows in England, the Graſs in general being deſtroyed; ſo that Ruſhes, Docks, and other trumpery, make up the burden of theſe Lands: but if theſe meadows were judiciouſly managed, and never floated till March or April, the quantity of ſweet good Graſs would be thereby greatly increaſed, and the beautiful verdure of the meadows preſerved: but there is little hope of convincing thoſe perſons by any arguments, who are ſo much wedded to their own prejudices, as to ſhut their eyes and ears againſt experiments or reaſon. Where the Land is very hot and dry, and it lieth convenient to be watered at a ſmall expence, it ſhould be repeated every week in dry hot weather, which will prove a great advantage to the Land. But whenever this is done, there ſhould no cattle be admitted while it is wet, for they will poach, and ſpoil the turf.

Another great improvement of Land, is by burning of it, which, for ſour, heathy, and ruſhy Land, be it either hot or cold, wet or dry, is a very great improvement; ſo that ſuch Lands will, in two or three years after burning, yield more, excluſive of the charges, than the inheritance was worth before; but this is not to be practiſed on rich fertile Land; for as the fire deſtroys the acid juice, which occaſions ſterility in the poor Land, ſo it will in like manner conſume the good juices of the richer Land, and thereby impoveriſh it, ſo that it hath been with great reaſon diſuſed in deep rich countries.

The uſual method of burning Land is, to pare off the turf with a breaſt plough, turning it over as it is cut, that it may dry the better. And if it proves hot dry weather when this work is done, then it needs no more turning; but if rain ſhould fall, it muſt be turned, and the turfs ſet a little hollow, that they may dry the better; and when they are thorough dry, they may be laid on ſmall heaps, about half a cart load on a heap, or leſs, for the ſmaller the heaps are, provided there is quantity enough to make a good fire, ſo as to conſume the whole to aſhes, it is the better; if the turf be full of fibrous roots, or hath much Moſs or Fern on it, it will burn without any additional fuel; but if it hath not, the heaps ſhould be raiſed on ſmall bundles of Heath, Fern, Gorze, &c. which will ſet the whole on fire; yet there ſhould be no more of theſe things applied, than what is neceſſary to kindle the fire, becauſe the ſlower the turf conſumes, the better will be the aſhes. When the turf is wholly conſumed, the aſhes ſhould be equally ſcattered over the ground in a calm day, leſt the wind ſhould drive it in heaps. Then the Land ſhould be gently ploughed, and the ſeeds ſown thereon; for if the ground is ploughed too deep, the aſhes will be buried too low for the roots of the Graſs or Corn to reach them for a conſiderable time; nor ſhould the aſhes lie too near the ſurface, becauſe then the roots will reach them too ſoon, and the ſtrength of the aſhes will be ſpent to nouriſh only the blade, ſo that the Corn will grow too rank in winter; and when the roots in the ſpring ſtrike down lower, they will meet with a poorer ſoil, nor will the ſtalks and ears have ſo much advantage from the improvement, as the uſeleſs blade. But when care is taken in this particular, it is wonderful what ſucceſs it hath; for by this method the pooreſt plains, and ſour heathy Lands, have been rendered as fertile as almoſt any good cultivated ground whatever.

It is alſo a very great improvement, where Land is overgrown with Broom, Furz, &c. to ſtub them up by the roots, and when they are dry, lay them on heaps, and cover them with the parings of the earth, and burn them, and ſpread the aſhes over the ground. By this method vaſt tracts of Land, which at preſent produce little or nothing to their owners, might be made good at a ſmall expence, ſo as to become good eſtates to the proprietors.

There are ſeveral other methods of improving Land beſide thoſe here mentioned, as by planting of wood, or adapting the ſeveral ſorts of plants to the particular ſoils with which they agree; but as moſt of theſe things are treated of under the ſeveral articles where theſe plants are mentioned, I ſhall forbear to repeat them in this place, but ſhall beg leave to offer a few general hints on the preſent ſituation of the Lands in England, which may probably excite ſome abler hand to undertake a fuller and more complete diſquiſition of this ſubject.

For ſome years paſt, the quantity of Corn raiſed in England, has greatly exceeded the conſumption, ſo that great quantities of Corn have been exported, by which great ſums of money have been brought into England; but this was accidental; for had not the crops failed in the neighbouring countries, there would have been no demand for the produce of England, ſo that the quantity here grown muſt have reduced the price ſo low, as to have almoſt ruined the farming intereſt; nor is it poſſible to contrive any ſcheme, in a country circumſtanced as this, whereby the public may not, at times, ſuffer from the extravagant price, which, in a ſcarcity, this commodity may be raiſed to; or, on the other hand, the farmers are ſometimes almoſt undone by the low price which it is often reduced to in times of plenty; and ſurely there can be no one thing more worthy of the ſerious attention of every perſon, who has the leaſt regard for the public welfare, than this, of always making ſuch proviſion of Corn, againſt accidental ſcarcities, as that the inhabitants may never be diſtreſſed for want of the ſtaff of life, or the price be ſo high, as that the common people cannot purchaſe it. If I am not greatly miſtaken, there has been, within the ſpace of three or four years, ſuch a diſproportion in the price of Corn, as can hardly be conceived, and this within the memory of numbers of perſons; the time I mean is between 1705 and 1709, in the compaſs of which time the peck loaf of fine bread was riſen from fourteen pence to four ſhillings and twopence; the low price of this commodity was as detrimental to the farmers, as the extravagant price was afterward to the public, neither of which would have ſo ſeverely felt the effects, had there been public granaries where the Corn might have been depoſited, and this purchaſed from the farmer, at a price by which he might live, at the public expence, and ſold out again at an eaſy rate in times of ſcarcity; but I fear this is not an age for encouraging any ſcheme for public utility, when in every thing of this kind, however beneficial it may be to the country, and though propoſed as ſuch to the public, if it meets with any reception, it is with a view to turn it to private intereſt; the practice of turning all things into private jobs, has ſo much prevailed of late years, as to have almoſt extinguiſhed every ſocial virtue; but I fear I may have incurred the cenſure of many for this digreſſion; but, be it as it will, I could not omit it, when it ſo properly came in my way; and as it is from a ſincere love and regard to my country, that I have mentioned this, ſo it may be hoped, that if any harſh expreſſion has been uſed, it will be forgiven. But to return to my ſubject; as the quantity of Land now in tillage is very great in England, from the deſtruction of woods, the ploughing up of downs, the incloſing of commons, &c. ſo that, unleſs there happens a failure in the crops of Corn in great part of England, the markets muſt be ſo low, as that the farmer will always find it difficult to ſupport his family, and pay his rent; the firſt muſt be done, let the landlord fare as he will, for the farmers know, that when the farms are occupied by the landlords, few of them can make the produce of the Land and pay their expence, ſo that the whole rent of the farm is often ſunk, beſide the trouble and fatigue of managing the farms; and it is greatly to be feared, from the preſent condition of the farmers in general, that many landlords will be obliged to undertake this diſagreeable affair, which will be the more ſo, as their Lands will be left without ſtock, and the ſoil exhauſted, and overgrown with weeds, which will require ſome years to put into proper condition, and will be attended with great expence.

The extraordinary price which Corn bore ſome years ſince, tempted the farmers to break up the downs in many parts of England; and the landlords were brought to comply with the requeſt of the farmer, for the ſake of a little advance of the rent, not conſidering the future conſequence of it; ſo that hereby great extents of downs have been ruined, and not likely to be recovered again; for the ſoil in many places was not more than four or five inches deep, upon beds of flint or chalk, which, in ploughing, were turned up on the ſurface, and the little ſoil which covered them, was in a few years ſo much exhauſted, as not to produce the quantity of grain which was ſown upon them; and as there was no probability of procuring dreſſing for the Lands, the farmers have been obliged to throw them up, which now lie waſte, and appear like quarries of flints, or beds of chalk, without Graſs, or almoſt any other plant growing upon them. By this paſſion for ploughing, the farmers have leſſened their ſtock of cattle, and, of conſequence, their quantity of manure has been leſſened in proportion, ſo that they have either been obliged to purchaſe dreſſing at a great expence, or deſtroy their Lands of their vegetative quality: by the former method, when grain bears a low price, the farmer is ruined, and by the latter, every one muſt know what will be the conſequence to both tenant and landlord; therefore it is a matter of great concern to the proprietors of Lands, to ſee that no more ground in their farms is kept in tillage, than the tenant can ſupply with dreſſing, ſo as to maintain the Land in heart; and that a proper ſtock of cattle be kept up, in proportion to the ſize of the farms, which cannot be done where there is not a proportion of paſture kept to that of the arable Land in each farm. There are many perſons, who, by a miſtake in the article of incloſing Lands, are likely to fall into a great error, by ſuppoſing, that the incloſing of commons will be a great advantage to their eſtates, and perhaps there may be tenants on their eſtates, who may encourage the gentlemen ſo to do, from a preſent intereſt of their own; but wherever this has been done, the eſtates have ſoon fallen in their rents, much lower than the addition made by incloſing the commons, which muſt always be the caſe; for if there is not common paſture, where the farmers can turn out their cattle in ſummer, it cannot be ſuppoſed they can keep up a ſtock of live cattle upon their incloſed paſture; ſo that, although the dividing and incloſing the Lands in the common fields would be a very great benefit, yet the deſtroying of paſture commons would on the other extreme be a national diſadvantage and loſs. There are many other particulars, which might be here enumerated, to ſhew the cauſe of the low condition of the farmers in general; but theſe few hints may probably lead ſome perſons of abler heads to the conſideration of this affair, ſo I ſhall not enlarge upon them here.

LANIGEROUS TREES are ſuch as bear a woolly or downy ſubſtance, as is commonly contained in the katkins of Willows, &c.

LANTANA. Lin. Gen. Plant. 683. Camara. Plum. Nov. Gen. 32. tab. 2. American Viburnum, or Camara.

The CHARACTERS are,

The empalement of the flower is cut into four ſegments. The flower is monopetalous, of an irregular ſhape, having a cylindrical tube, which extends beyond the empalement, and is ſpread open at the brim, where it is divided into five ſegments. In the center of the flower is ſituated the pointal, ſupporting a crooked ſtigma, attended by four ſtamina, two being longer than the other. The pointal afterward changes to a roundiſh fruit, opening into two cells, and incloſing a roundiſh ſeed.

This genus of plants is ranged in the ſecond ſection of Linnæus's fourteenth claſs, intitled Didynamia Angioſpermia, which includes thoſe plants whoſe flowers have two long and two ſhorter ſtamina, and the ſeeds are incloſed in the capſule.

The SPECIES are,

1. LANTANA (*Aculeata*) foliis oppoſitis, caule aculeato ramoſo, floribus capitato-umbellatis. Lin. Sp. 874. *Lantana with leaves growing oppoſite, a branching prickly ſtalk, and umbellated flowers growing in heads.* Viburnum Americanum odoratum, urticæ foliis latioribus ſpinoſum, floribus miniatis. Pluk. Alm. 285. tab. 223. *Sweet prickly American Viburnum, with broad Nettle leaves, and carmine flowers.*

2. LANTANA (*Inerma*) caule inermi, foliis lanceolatis dentatis alternis, floribus corymboſis. *Lantana with a ſmooth ſtalk, ſpear-ſhaped indented leaves placed alternate, and flowers growing in round bunches.* Periclymenum rectum, ſalviæ foliis majoribus oblongis, mucronatis, ſubtus villoſis, alternatim ſitis, flore & fructu minoribus. Sloan. Cat. Jam. 164. *Upright Honeyſuckle with larger, oblong, acute-pointed Sage leaves, which are hairy on their under ſide, placed alternate, and a ſmaller flower and fruit.*

3. LANTANA (*Lanuginoſa*) caule ramoſo lanuginoſo, foliis orbiculatis crenatis oppoſitis, floribus capitatis. *Lantana with a hairy branching ſtalk, round crenated leaves placed oppoſite, and flowers collected in heads.* Periclymenum rectum, ſalviæ folio rugoſo minore, ſubrotundo. Cat. Jam. 164. *Upright Honeyſuckle with a ſmaller rough roundiſh leaf.*

4. LANTANA (*Trifolia*) foliis ternis, caule inermi ſpicis oblongis imbricatis. Lin. Sp. Plant. 873. *Lantana with leaves placed by threes round the ſtalk, without ſpines, and oblong imbricated ſpikes of flowers.* Camara trifolia, purpuraſcente flore. Plum. Nov. Gen. 32. *Three-leaved Camara, with a purpliſh flower.*

5. LANTANA (*Urticæfolia*) caule aculeato, foliis oblongo-cordatis ſerratis oppoſitis, floribus corymboſis. *Lantana with a prickly ſtalk, oblong, heart-ſhaped ſawed leaves, and flowers growing in a corymbus.* Periclymenum rectum urticæ folio hirſuto majore, flore flavo. Sloan. Cat. Jam. 163. *Upright Honeyſuckle with a larger Nettle leaf, and a yellow flower.*

6. LANTANA (*Camara*) caule inermi, foliis ovato-lanceolatis, ſerratis, rugoſis, floribus capitatis lanuginoſis. *Lantana with a ſmooth ſtalk, oval, ſpear-ſhaped, rough, ſawed leaves, and flowers growing in woolly heads.* Periclymenum rectum, ſalviæ folio rugoſo, majore, ſubrotundo & bullato. Sloan. Cat. Jam. 163. *Upright Honeyſuckle with a large, rough, Sage leaf, which is roundiſh and ſtudded.*

7. LANTANA (*Bullata*) foliis oblongo-ovatis acuminatis ſerratis rugoſis alternis, floribus capitatis. *Lantana with oblong, oval-pointed, ſawed leaves, which are rough, placed alternate, and flowers growing in heads.* Periclymenum rectum, ſalviæ folio rugoſo, minore, bullato,

flore albo. Sloan. Cat. 163. *Upright Honeyſuckle with a ſmaller rough Sage leaf, which is ſtudded, and a white flower.*

8. LANTANA (*Alba*) caule inermi, foliis ovatis ſerratis, floribus capitatis alaribus ſeſſilibus. *Lantana with a ſmooth ſtalk, oval ſawed leaves, and flowers growing in heads proceeding from the wings of the leaves, ſitting cloſe to the ſtalks.* Camara foliis urticæ, floribus minoribus albis, ex alis foliorum prodeuntibus. Houſt. *Camara with a Nettle leaf, and ſmaller white flowers proceeding from the wings of the leaves.*

9. LANTANA (*Annua*) foliis quaternis, caule aſpero, ſpicis oblongis. *Four-leaved Lantana with a rough ſtalk, and oblong ſpikes of flowers.* Periclymenum rectum humilius, folio rugoſo majore, flore purpureo, fructu oblongo, eſculento purpureo. Sloan. Cat Jam. 164. *Lower upright Honeyſuckle with a larger rough leaf, a purple flower, and an oblong, purple, eſculent fruit.*

10. LANTANA (*Anguſtifolia*) caule inermi, foliis ovato-lanceolatis oppoſitis, floribus capitatis pedunculis longiſſimis. *Lantana with a ſmooth ſtalk, oval ſpear-ſhaped leaves placed oppoſite, flowers collected in heads, and very long foot-ſtalks.* Periclymenum rectum, ſalviæ folio rugoſo, longo & anguſtiſſimo. Sloan. Cat. 164. *Upright Honeyſuckle with a rough Sage leaf, which is long and narrow.*

11. LANTANA (*Africana*) foliis alternis ſeſſilibus, floribus ſolitariis. Hort. Cliff. 320. *Lantana with alternate leaves ſitting cloſe to the ſtalks, and flowers growing ſingly.* Jaſminum Africanum, illicis folio, flore ſolitario ex foliorum alis proveniente albo. Com. Plant. Rar. 6. tab. 6. *African Jaſmine with an Ilex leaf, and a ſolitary white flower coming from the wing of the leaves.*

12. LANTANA (*Salvifolia*) foliis oppoſitis ſeſſilibus, floribus racemoſis. Lin. Sp. 875. *Lantana with leaves placed oppoſite cloſe to the ſtalks, and flowers in a racemus.* Frutex Africanus, foliis conjugatis ſalviæ anguſtis, floribus hirſutis. Herm. Afr. 10.

The firſt ſort is pretty common in thoſe Engliſh gardens, where there are collections of exotic plants; this grows naturally in Jamaica, and moſt of the other iſlands in the Weſt-Indies, where it is called wild Sage, as are ſeveral of the other ſorts which are not diſtinguiſhed by the inhabitants. It riſes with a woody ſtalk five or ſix feet high, ſending out many branches, which have four angles, armed with ſhort crooked ſpines. The leaves are placed oppoſite; they are oval, ſpear-ſhaped, about an inch and a half long, and three quarters of an inch broad, hairy, and ſtand upon ſhort foot-ſtalks; toward the end of the branches the flowers come out from the wings of the ſtalks, two foot-ſtalks ariſing from the ſame joint, one on each ſide; they are near two inches long, and are terminated by roundiſh heads of flowers, thoſe which are on the outſide and form the border, are firſt of a bright red, or ſcarlet colour; theſe change to a deep purple before they fall. Thoſe flowers which are in the center are of a bright yellow, but after ſome time fade to an Orange colour. The flowers are ſucceeded by roundiſh berries, which, when ripe, turn black, having a pulpy covering over a ſingle hard ſeed. This plant in the Weſt-Indies continues to flower moſt part of the year; but in England they begin to flower in June, and continue in ſucceſſion till near Chriſtmas, and the early flowers are ſucceeded by ripe ſeeds.

The ſecond ſort grows naturally in Jamaica; this riſes with a ſlender, ſmooth, ſhrubby ſtalk, about four feet high, dividing into many ſmall quadrangular branches which grow erect, garniſhed with ſpear-ſhaped leaves about two inches long, and one inch broad, indented on their edges, and hoary on their under ſide, ſtanding alternate upon ſhort foot-ſtalks. Toward the end of the branches the foot-ſtalks of the flowers ariſe alternately from the wings of the leaves; theſe are very ſlender, and ſupport ſmall heads of pale purple flowers, which are ſucceeded by ſmall purple berries, each having one ſeed. This flowers at the ſame time with the former ſort. The ſeeds of this ſort were firſt ſent me by the late Dr. Houſtoun, from La Vera Cruz, but I have ſince received them from Jamaica.

The third ſort was ſent me from La Vera Cruz, by the late Dr. Houſtoun; this riſes with a ſhrubby ſtalk about three feet high, dividing into ſeveral upright branches. The leaves are oblong, and ſawed on their edges, ſtanding oppoſite, on the lower part of the branches, but toward the upper part they are placed by threes round the branches. The foot-ſtalks of the flowers come out from the wings of the leaves; they are near three inches long, ſuſtaining an oblong ſpike of purple flowers, which come out from imbricated ſcales, which end in acute points. The flowers are ſucceeded by pretty large purple berries. This flowers at the ſame time with the former ſorts.

The ſeeds of the fourth ſort were ſent me from the Havanna, by the late Dr. Houſtoun; this riſes with a ſhrubby ſtalk about three feet high, covered with a gray bark, which is woolly. It divides into branches by pairs, which are garniſhed with round leaves, indented on their edges, whoſe upper ſurface is corrugated and rough, like thoſe of Sage; they are placed oppoſite, ſtanding upon ſhort foot-ſtalks. At the end of the branches ariſe the foot-ſtalks of the flowers, which are ſhort, and ſuſtain a globular head of purple flowers; theſe are ſucceeded by pretty large purple berries containing one ſeed. This flowers at the ſame time with the former ſorts.

There is a variety of this with white flowers, whoſe leaves are not quite ſo round, nor are they crenated on their edges; but I ſuſpect they both come from the ſame ſeeds, ſo I have not enumerated it as a diſtinct ſpecies.

The fifth ſort was ſent me from La Vera Cruz, by the late Dr. Houſtoun; this riſes with a woody branching ſtalk four or five feet high, garniſhed with oblong heart-ſhaped leaves, which are ſawed on their edges, and end in acute points. At the end of the branches the flowers come out in round bunches, ſtanding upon ſlender upright foot-ſtalks, about one inch long. The flowers are yellow, and grow in looſer bunches or heads than thoſe of the former ſorts, but flowers at the ſame time.

The ſixth ſort riſes with a woody branching ſtalk five or ſix feet high, covered with a dark brown bark. The branches are more divided than thoſe of the other ſorts, and are much more ligneous. The leaves are two inches and a half long, and one inch and a quarter broad, deeply ſawed on their edges, and their upper ſurface very rough, and many of them cloſely ſet with white prominent ſpots as if ſtudded; theſe are placed alternately on the branches. The flowers come out from the wings of the ſtalk, ſtanding upon pretty long foot-ſtalks; they are white, and are collected in ſmall woolly heads. This flowers about the ſame time with the former ſorts.

The ſeventh ſort riſes with a branching ſhrubby ſtalk about four feet high, covered with a dark brown bark, and garniſhed with ſmall, oblong, oval leaves, ending in acute points; they are an inch long, and half an inch broad, very much veined on their upper ſide, ſtanding alternately pretty cloſe to the branches. The flowers come out at the end of the branches upon ſhort foot-ſtalks, in cloſe ſmall heads; theſe are white, and make but little appearance. It flowers at the ſame time with the former.

The eighth ſort was ſent me by the late Dr. Houſtoun, from Campeachy; this hath a ſlender ſhrubby ſtalk which riſes three or four feet high, dividing into many ſlender, ſmooth, ſquare branches, which are garniſhed with ſmall, oval, ſawed leaves placed oppoſite; from the wings of the ſtalk, at every joint, come out the flowers; they are ſmall, white, and are collected in cloſe heads; theſe come out by pairs, and ſit cloſe to the branches. This flowers at the ſame time with the former.

The ninth ſort is annual; this was firſt ſent me by the late Dr. Houſtoun from La Vera Cruz, but I have ſince received the ſeeds from the north ſide of the iſland of Jamaica; it riſes with a ſtrong, upright, rough ſtalk near three feet high, dividing toward the top into two or three erect branches, which are garniſhed with oblong, oval, ſawed leaves, ending in acute points; they are placed by fours at each joint, and are a little woolly on their under ſide. The flower-ſtalks ariſe by pairs, and ſometimes three come out at the ſame joint; they are from two to three inches long, and ſuſtain a thick ſpike of large purple flowers,' which are ſucceeded by large purple berries that are very ſucculent, and are frequently eaten by the inhabitants. This ſort flowers in July, provided the plants are raiſed early in the ſpring and brought forward, and the ſeeds will ripen in autumn, ſoon after which the plants decay.

The tenth ſort grows naturally in Jamaica, from whence the late Dr. Houſtoun ſent me the ſeeds; this riſes with a ſlender, ſmooth, branching ſtalk three feet high. The branches are garniſhed with oval ſpear-ſhaped leaves two inches long, and one inch broad; they are crenated on their edges, and rough on their upper ſide, ſtanding by pairs oppoſite, upon very ſhort foot-ſtalks, having an agreeable odour. The flowers come out from the wings of the ſtalk, upon very long foot-ſtalks; they are placed oppoſite the whole length of the young branches, ſuſtaining ſmall round heads of white flowers; theſe appear at the ſame time with the other ſorts, but rarely produce ſeeds in England.

Theſe plants are all of them eaſily propagated by cuttings except the ninth, which is an annual plant, ſo can only be propagated by ſeeds. They may alſo be propagated by ſeeds, which ſeveral of the ſorts produce in England, and the others may be eaſily procured from the Weſt-Indies, where there are a greater variety of theſe plants growing naturally, than are at preſent known in Europe; they are all of them called Wild Sage, by the inhabitants of the Britiſh Iſlands, but they do not diſtinguiſh the ſorts. Theſe ſeeds ſhould be ſown in pots filled with light earth, and plunged into a hot-bed of tan; the reaſon for my adviſing them to be ſown in pots, is, becauſe the ſeeds frequently remain long in the ground before they vegetate; therefore if the plants ſhould not come up the ſame year, the pots ſhould be placed in the ſtove in winter, and the following ſpring plunged into a new hot-bed, which will bring up the plants. When theſe are fit to remove they ſhould be each planted in a ſmall pot, and plunged into another hot-bed, obſerving to ſhade them till they have taken new root; then they ſhould have air admitted to them every day, in proportion to the warmth of the ſeaſon, to prevent their being drawn up with weak ſtalks; afterward they muſt be treated in the ſame manner as other plants from the ſame country, till they have obtained ſtrength; then they may be removed into an airy glaſs-caſe, or a dry ſtove, where they may have a large ſhare of air in warm weather, but protected from the cold. This is neceſſary for the young plants, which ſhould not the firſt year be expoſed to the open air, but afterward they may be placed abroad in the warmeſt part of ſummer, and in winter placed upon ſtands in the dry ſtove, where they will continue long in flower, and many of the ſorts will ripen their ſeeds; but in winter they ſhould be ſparingly watered, for much moiſture will rot their roots.

If they are propagated by cuttings, the beſt time for planting them is in July, after the plants have been expoſed to the open air for about a month, by which time the ſhoots will be hardened ſo as to be out of danger of rotting with a little moiſture. Theſe cuttings ſhould be planted in ſmall pots filled with light earth, and plunged into a moderate hot-bed; and if they are ſcreened from the violence of the ſun in the middle of the day, they will be rooted in about ſix weeks time, when they muſt be hardened gradually to bear the open air, and afterward treated as the old plants.

The eleventh ſort has been long in the Engliſh gardens, and is commonly called the Ilex-leaved Jaſmine. This ſort riſes with a ſhrubby ſtalk five or ſix feet high, ſending out many irregular branches, which are cloſely garniſhed with thin oval leaves ending in points, and ſawed on their edges, which embrace the branches with their baſe, and from the boſom of each leaf comes out one ſolitary white flower, which is cut at the top into five parts, and at firſt ſight has the appearance of a Jaſmine flower; but when cloſer viewed, the tube will be found curved in the ſame manner with thoſe which Dr. Linnæus titles ringent flowers. The flowers are not ſucceeded by ſeeds in England, but the plants are eaſily propagated by cuttings, which, if planted upon an old hot-bed any time in July, and covered with a bell or hand-glaſs, and ſhaded from the ſun, will put out roots in a month or five weeks; then they may be planted in pots, and placed in the ſhade till they have taken freſh root; after which they may be removed to a ſheltered ſituation, where they may remain till the froſts come on. This plant was brought from the Cape of Good Hope, ſo is not very tender, therefore may be preſerved in a good green-houſe in winter; but during that ſeaſon it muſt have a large ſhare of air in mild weather, otherwiſe it is apt to grow mouldy, and this will cauſe the tender branches to decay. In the ſummer ſeaſon it may be expoſed in the open air, with other green-houſe plants, in a ſheltered ſituation, where it will add to the variety; and although the flowers are ſmall, and are produced ſingly from between the leaves, ſo do not make any great appearance; yet as there is a ſucceſſion of theſe flowers moſt part of the year, and the leaves continuing green throughout the year, it is rendered worthy of a place in every collection of plants.

The laſt ſort is a native of Africa; this riſes with a ſhrubby four-cornered ſtalk eight or ten feet high, covered with a pale looſe bark, ſending out many ſide branches, garniſhed with rough leaves five or ſix inches long, whoſe baſe embrace the ſtalks, but they end with ſharp points, and are downy on their under ſide; the branches are terminated by looſe ſpikes of pale purple flowers, covered with a meally down; theſe appear in ſummer, but are rarely ſucceeded by ſeeds in England.

This is propagated by cuttings in the ſame manner as the eleventh ſort, and the plants require the ſame treatment.

LANUGINOUS, ſignifies downy, or to be covered with a ſoft down, as a Quince.

LAPATHUM. See Rumex.

LAPSANA. Lin. Gen. Plant. 823. Lampſana & Rhagadiolus. Tourn. Inſt. R. H. 479. tab. 272. Nipplewort.

The Characters are,

The flower is compoſed of ſeveral hermaphrodite florets, which are included in one common imbricated empalement. The florets have one petal, which is tubulous and ſtretched out at the top, in ſhape of a tongue; theſe have each five ſhort hairy ſtamina, terminated by cylindrical ſummits which coaleſce. The germen is ſituated at the bottom of the floret, ſupporting a ſlender ſtyle, crowned by a reflexed bifid ſtigma; the germen afterward becomes an oblong three-cornered ſeed, ſituated in the ſcale of the empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's nineteenth claſs, intitled Syngeneſia Polygamia Æqualis, in which he ranges thoſe plants with hermaphrodite flowers which are fruitful, whoſe ſtamina and ſtyle are connected together; and to this genus he has joined the Rhagadiolus and Zacintha of Tournefort, making them only ſpecies of the ſame genus.

The Species are,

1. Lapsana (*Communis*) calycibus fructûs angulatis, pedunculis tenuibus ramoſiſſimis. Hort. Cliff. 384. *Nipplewort with angular empalements to the fruit, and very narrow branching foot-ſtalks.* Lampſana. Dod. p. 675. *Common Nipplewort.*
2. Lapsana (*Rhagadiolus*) calycibus fructûs undique patentibus, radiis ſubulatis, foliis lyratis. Hort. Upſal. 245. *Nipplewort with empalements to the fruit ſpreading open every way, awl-ſhaped rays, and ſpear-ſhaped undivided*

vided leaves. Rhagadiolus alter. Cæſalp. 511. *Another Rhagadiolus.*

3. Lapsana (*Lampſanæfoliis*) calycibus fructûs undique patentibus, radiis ſubulatis, foliis lyratis. Hort. Upſal. 245. *Nipplewort with empalements to the fruit ſpreading open every way, awl-ſhaped rays, and harp-ſhaped leaves.* Rhagadiolus Lampſanæ foliis. Tourn. Cor. 36. *Rhagadiolus with a Nipplewort leaf.*

4. Lapsana (*Zacintha*) calycibus fructûs toruloſis depreſſis obtuſis ſeſſilibus. Lin. Sp. Plant. 811. *Nipplewort with a depreſſed knotted empalement which is obtuſe, and ſits cloſe to the branches.* Zacintha ſive cichorium verrucarium. Tourn. Inſt. 476. *Zacintha, or warted Cichory.*

The firſt ſort is a common weed, which grows by the ſide of foot-paths and hedges in moſt parts of England, ſo is not permitted to have room in gardens.

The ſecond and third ſorts grow naturally in Portugal, from whence I have received their ſeeds. Theſe are annual plants, of no beauty or uſe, but are preſerved in botanic gardens for the ſake of variety. If the ſeeds of theſe are permitted to ſcatter, the plants will come up without trouble, and two or three of them will be enough to leave to keep the ſorts.

The fourth ſort grows naturally in Italy; this is alſo an annual plant, of neither uſe or beauty, but is like the others kept for variety. If the ſeeds of this ſort ſcatter in the autumn, the plants will come up better than if ſown in the ſpring. The plants require no culture, but will thrive like weeds.

LARIX. Tourn. Inſt. R. H. 586. tab. 353. Pinus. Lin. Gen. Plant. 956. The Larch-tree; in French, *Meleſe.*

The Characters are,

It hath male and female flowers growing ſeparate on the ſame tree. The male flowers are diſpoſed in a ſcaly katkin; theſe have no petal, but a great number of ſtamina which are connected in a column below, but are ſeparated at their points, and are terminated by erect ſummits. The female flowers are diſpoſed in a conical ſhape, having no petals; theſe are placed by pairs under each ſcale, having a ſmall germen, ſupporting an awl-ſhaped ſtyle, crowned by a ſingle ſtigma. The germen afterward becomes a nut with a membraneous wing, incloſed in the ſcales of the cones.

This genus of plants is ranged in the ninth ſection of Linnæus's twenty-firſt claſs, intitled Monœcia Monodelphia, the ſame tree having male and female flowers in different parts, and the ſtamina of the male flowers are united in one cluſter. Dr. Linnæus has joined this genus, and the Abies of Tournefort, to the genus of Pinus, which, according to his ſyſtem, may very well be brought together; but as Tournefort and all former botaniſts have ſeparated them by the form of their leaves, thoſe of the Abies coming out ſingle from the branches, thoſe of the Pine coming out by two, three, or five out of each ſheath, and thoſe of this genus ariſing in cluſters in the bottom, but are ſpread above like a painter's pencil; ſo theſe diſtinctions being pretty generally known by gardeners, I have choſen to continue them under their former ſeparate titles to prevent confuſion.

The Species are,

1. Larix (*Decidua*) foliis deciduis, conis ovatis obtuſis. *Larch-tree with deciduous leaves, and oval obtuſe cones.* Larix folio deciduo, conifera. J. B. 1. p. 265. *Common Cone-bearing Larch-tree.*
2. Larix (*Chinenſis*) foliis deciduis, conis mucronatis ſquamis acutis. *Larch-tree with deciduous leaves, and pointed cones having acute ſcales.*
3. Larix (*Cedrus*) foliis acutis perennantibus, conis obtuſis. *Larch-tree with acute evergreen leaves and obtuſe cones.* Cedrus conifera, foliis laricis. C. B. P. 490. *Cone-bearing Cedar with a Larch-tree leaf, or the Cedar of Lebanus.*

The firſt ſort grows naturally upon the Alps and Apennines, and of late years has been very much propagated in England. This tree is of quick growth, and will riſe to the height of fifty feet; the branches are ſlender, and their ends generally hang downward. Theſe are garniſhed with long narrow leaves, which ariſe in cluſters from one point, and ſpread open above like the hairs of a painter's bruſh; they are of a light green, and fall away in autumn like other deciduous trees. In the month of April the male flowers appear, which are diſpoſed in form of ſmall cones; the female flowers are collected into oval obtuſe cones, which in ſome ſpecies have bright purple tops, and in others they are white: theſe differences are accidental, for I have found the ſeeds taken from either of theſe varieties, will produce plants of both ſorts; the cones are about one inch long, obtuſe at their points, and the ſcales lie over each other, and are ſmooth; under each ſcale there is generally lodged two ſeeds which have wings.

There are two other varieties of this tree, one of which is a native of America, and the other of Siberia; the latter requires a colder climate than England, for they are very apt to die in ſummer here, eſpecially if they are planted on a dry ſoil. The cones of this ſort which have been brought to England, ſeem to be in general larger than thoſe of the common kind; but there is ſo little difference between the trees in their characteriſtic notes, as not to be diſtinguiſhed as different ſpecies, though by the growth of the trees there is a remarkable difference.

The cones of the ſecond ſort were ſent from China, to the Right Hon. the Earl of Northumberland, who was ſo good as to communicate ſome of the ſeeds to me, which were ſown in the Chelſea garden, where they ſucceeded, as they alſo did in his Lordſhip's garden at Stanwick. The cones of this ſort were much larger than thoſe of the common ſort, and ended in acute points; the ſcales were prominent like thoſe of the Scotch Pine, and had ſo little reſemblance to thoſe of the Larch, as that every one who ſaw them, imagined they were a ſort of Pine; they were titled, Fir good to keep up banks. As theſe plants make but little progreſs the firſt year, ſo they were weak, and in the autumn caſting off their leaves, they were ſuppoſed to be dead, and moſt of the plants were thereby loſt; but thoſe which eſcaped, afterward ſhot their branches out horizontally, ſpreading cloſe to the ground, and by their preſent appearance, ſeem to be a ſhrub which never will riſe upright. This ſort is ſo hardy, as to thrive in the open air without any protection.

The common Larch is now very plenty in moſt of the nurſeries in England, and of late years there has been great numbers of the trees planted; but thoſe which have been planted in the worſt ſoil and in bad ſituations, have thriven the beſt; for where trees of equal ſize have been planted in good garden earth at the ſame time, the others on the cold ſtiff land, have in twelve years been twice the height of thoſe planted in good ground; which is an encouragement to plant theſe trees, ſince they will thrive in the moſt expoſed ſituations, provided they are planted in clumps near each other, and not ſingle trees; nor ſhould the plants which are planted in very open expoſed places be taken from warm nurſeries, but rather raiſed as near to the ſpot where they are to remain as poſſible; nor ſhould the plants be more than three or four years growth when planted, where they are deſigned to grow large; for though trees of greater ſize will remove very well, and grow ſeveral years as well as if they had not been tranſplanted; yet after twenty or thirty years growth they will frequently fail, where the young planted trees have continued very vigorous.

Theſe trees are raiſed from ſeeds, which moſt years ripen well in England: the cones ſhould be gathered about the end of November, and kept in a dry place till the ſpring, when they ſhould be ſpread on a cloth and expoſed to the ſun, or laid before a fire, which will cauſe the ſcales of the cones to open and emit their ſeeds. Theſe ſeeds ſhould be ſown on a border, expoſed to the eaſt, where the morning ſun only comes on it; or if they are ſown on a bed more expoſed to the ſun, they ſhould be ſcreened with mats from the ſun in the middle of the day; for when the plants firſt appear above ground, they are very impatient of heat;

and when the bed is much expoſed to the ſun, the ſurface of the ground will dry ſo faſt, as to require to have water very often, which frequently rots the tender ſtems of the plants; which will be prevented by properly ſhading them while young, and afterward they will be in no danger. Theſe young plants ſhould be conſtantly kept clean from weeds, and if they have made good progreſs, they may be tranſplanted the following autumn, otherwiſe they may remain in the ſeed-bed another year, eſpecially if the plants are not too cloſe together. When they are tranſplanted, it ſhould be performed in the autumn as ſoon as their leaves decay; they may be planted in beds at about ſix inches aſunder each way, which will be diſtance enough for the growth of the plants the two following years, by which time they will be fit to tranſplant where they are to remain.

When the young trees are planted out for good, they need not be more than eight or ten feet diſtant from each other, always planting them cloſer on expoſed ſituations, than where they are more defended; after the trees are planted, they will require no other care but to keep them clean from weeds for three or four years till the trees have obtained ſtrength, when they will over-top the weeds and prevent their growth; but the ground between theſe trees ſhould not be dug, for that I have found has greatly ſtopped their growth.

The Siberian Larch is of ſlow growth in this country, for when the ſpring is mild, the trees will begin to ſhoot in February, or early in March; and there are frequently ſharp froſts after, whereby theſe ſhoots are often killed, and this ſtops the growth of the trees. Likewiſe when they are planted on a warm dry ſoil, they are frequently killed by drought in the ſummer; therefore this is a very improper tree for this country, unleſs for ſome cold, moiſt, peaty land, where they may probably thrive, and in ſuch ſituations few other trees will grow.

The American or black Larch, thrives pretty well upon moiſt land, but on dry ground will make but little progreſs. A few of theſe trees by way of variety, may be allowed to have place in every collection of trees deſigned for pleaſure; but for profit, the common Larch is to be preferred to any other ſpecies.

In Switzerland, where theſe trees abound, and they have a ſcarcity of other wood, they build moſt of their houſes with it; and great part of their furniture is alſo made of the wood, ſome of which is white, and ſome red, but the latter is moſt eſteemed. The redneſs of the wood is by ſome ſuppoſed to be from the age of the trees, and not from any difference between them, but is rather owing to the quantity of turpentine contained in them. They frequently cut out the boards into ſhingles of a foot ſquare, with which they cover their houſes, inſtead of tiles or other covering; theſe are at firſt very white, but after they have been two or three years expoſed, become as black as charcoal; and all the joints are ſtopped by the reſin, which the ſun draws out from the pores of the wood, which is hardened by the air, and becomes a ſmooth ſhining varniſh, which renders the houſes ſo covered impenetrable to either wind or rain; but as this is very combuſtible, the magiſtrates have made an order of police, that the houſes ſo covered ſhould be built at a diſtance from each other to prevent fire, which has often done great damage in villages.

In moſt countries where this wood is in plenty, it is preferred to all the kinds of Fir for every purpoſe; and in many places there are ſhips built of this wood, which they ſay are durable; therefore this may be a very proper tree for planting upon ſome of the cold barren hills in many parts of England, which at preſent produce nothing to their proprietors, and in one age may be large eſtates to their poſterity, and a national advantage; which might be effected without a great expence, where the buſineſs is properly conducted.

The beſt method for doing this, would be by making ſmall nurſeries on or near the place where the plantation is intended to be made, in thoſe nurſeries the ſeeds ſhould be ſown; and if there are any poor cottagers there, theſe may be employed in raiſing of the plants, keeping of them clean, and afterward in tranſplanting them. This will leſſen the number of indigent poor, and by employing them in this ſort of huſbandry, they may be brought to have a love and regard for trees of their own planting, ſo will not be tempted to deſtroy them themſelves, or ſuffer others to do it; and as the ſeaſon for planting happens at a time of year when the farmers have little employment for their labourers, ſo the finding them uſeful employment this way, will be of infinitely more advantage than the giving them alms from the pariſh; and the children may be taught to weed and keep the young plants clean in ſummer, whereby they may be rendered uſeful, and kept from being burdenſome to the pariſhes.

From the Larch-tree is extracted the Venice turpentine, which the inhabitants of the valley of St. Martin near Lucern, make a conſiderable merchandize of. They collect this by boring holes in the trunk of the trees, at about two or three feet from the ground, into which they fix narrow troughs about twenty inches long; the end of theſe are hollowed like a ladle, and in the middle is a ſmall hole bored for the turpentine to run into a receiver, which is placed below it; as the turpentine runs from the trees, it paſſes along the ſloping gutter or trough to the ladle, and from thence runs through the holes into the receiver. The people who gather this viſit the trees morning and evening, from the end of May to September, to collect the turpentine from out of the receivers.

The third ſort is the Cedar of Libanus, which is a tree of great antiquity; and what is remarkable, this tree is not found as a native in any other part of the world, ſo far as hath come to our knowledge.

The cones of this tree are frequently brought from the Levant, which, if preſerved entire, will preſerve their ſeeds good for ſeveral years. The time of their ripening is commonly in the ſpring, and ſo conſequently are near one year old before we receive them, for which they are not the worſe, but rather the better; the cones having diſcharged a great part of their reſin by lying, and the ſeeds are much eaſier to get out of them than ſuch as are freſh taken from the tree.

The beſt way to get the ſeeds out is to ſplit the cones, by driving a ſharp piece of iron through the center lengthways, which will ſplit the cone; then you may pull the ſeeds out with your fingers, which you will find are faſtened to a thin leafy ſubſtance called wings, as are thoſe of the Fir-tree: but before the ſeeds are taken out, it will be proper to put the cones in water for twenty-four or thirty hours, which will render them eaſier to ſplit, ſo that the ſeeds may be taken out with greater ſafety; for there will require care in the doing of it, otherwiſe many of the ſeeds will be ſpoiled, as they are very tender, and will bruiſe where there is any force employed to get them out.

Theſe ſeeds ſhould be ſown in boxes or pots of light freſh earth, and treated as was directed for the Firs (to which I refer the reader) but only ſhall obſerve, that theſe require more ſhade in ſummer while young than the Firs, and ſhould be frequently refreſhed with water.

When the plants come up they muſt be guarded from the birds, otherwiſe they will pick off their tops, as they do of the young Firs where they are not guarded; they muſt alſo be conſtantly kept clean from weeds, and not placed under the drip of trees. The plants may remain in theſe boxes or pots in which they were ſown till the following ſpring, but it will be proper to place them under a frame in winter, or cover them with mats; for while they are young they are in danger of loſing their tops, if they are pinched by froſt, for the young plants often ſhoot late in the autumn. In the ſpring, before the plants begin to ſhoot, they ſhould be carefully taken up and tranſplanted into beds at about four inches diſtance, cloſing the earth gently to their roots; theſe beds ſhould be arched over with hoops, and covered with mats in the heat of the day, to ſhade the plants from the ſun till they have taken new root; and if the nights prove froſty, it will be proper to keep the mats over them in the night, but in cloudy or moiſt weather they muſt be always open. After the plants are well rooted, they will require no other care but to keep them clean from weeds, unleſs the ſeaſon ſhould prove very dry, in which caſe it will be proper to give them ſome water once or twice a week; but it muſt be but in ſmall quantities, for too much wet is often very injurious to them; ſo that it will be better to ſcreen them from the ſun in hot weather, to prevent the earth from drying too faſt, or cover the ſurface of the ground with moſs to keep it cool, than to water the plants often.

In theſe beds the plants may ſtand two years, then they ſhould be either tranſplanted to the places where they are deſigned to remain, or to a nurſery where they may grow two years more; but the younger theſe plants are when they are planted out for good, the better the trees will thrive, and the longer they will continue.

When theſe plants begin to ſhoot ſtrong, you will generally find the leading ſhoot incline to one ſide; therefore, if you intend to have them ſtrait, you muſt ſupport them with ſtakes, obſerving to keep the leader always cloſe tied up, until you have got them to the height you deſign them, otherwiſe their branches will extend on every ſide, and prevent their growing tall.

Theſe trees are by many people kept in pyramids, and ſheared as Yews, &c. in which form they loſe their greateſt beauty; for the extenſion of the branches is very ſingular in this tree, their ſhoots for the moſt part are declining, and thereby ſhewing their upper ſurface, which is conſtantly clothed with green leaves in ſo regular a manner, as to appear at ſome diſtance like a green carpet; and theſe waving about with the wind, make one of the moſt agreeable proſpects that can be to terminate a viſta, eſpecially if planted on a riſing ground.

It is matter of ſurpriſe to me, that this tree hath not been more cultivated in England formerly, for till within a few years paſt, there were but few here; ſince it would be a great ornament to barren bleak mountains, where few other trees will grow ſo well, it being a native of the coldeſt parts of Mount Libanus, where the ſnow continues great part of the year. And from the obſervations I have made of thoſe now growing in England, I find they thrive beſt on the pooreſt ſoil; for ſuch of them as have been planted in a ſtrong, rich, loamy earth, have made but a poor progreſs, in compariſon to ſuch as have grown upon a ſtony meagre ſoil. And that theſe trees are of quick growth, is evident from four of them now growing in the phyſic garden at Chelſea, which (as I have been credibly informed) were planted there in the year 1683, and at that time were not above three feet high; two of which trees are at this time (viz. 1766) upwards of twelve feet and a half in girt, at two feet above ground, and their branches extend more than twenty feet on every ſide their trunks; which branches (though they are produced twelve or fourteen feet above the ſurface) do at every termination hang very near the ground, and thereby afford a goodly ſhade in the hotteſt ſeaſon of the year.

The ſoil in which theſe trees are planted, is a lean hungry ſand mixed with gravel, the ſurface of which is ſcarcely two feet deep before a hard rocky gravel appears. Theſe trees ſtand at four corners of a pond, which is bricked up within two feet of their trunks, ſo that their roots have no room to ſpread on one ſide, and conſequently are cramped in their growth; but whether their ſtanding ſo near the water may not have been advantageous to them, I cannot ſay, but ſure I am, if their roots had had full ſcope in the ground, they would have made a greater progreſs. I have alſo obſerved, that lopping or cutting of theſe trees is very injurious to them (more, perhaps, than to any other of the reſinous trees) in retarding their growth; for two of the four trees above-mentioned, being unadviſedly planted near a green-houſe, when they began to grow large had their branches lopped, to let the rays of the ſun into the houſe, whereby they have been ſo much checked, as at preſent they are little more than half the ſize of the other two.

Theſe trees have all of them produced, for ſeveral years, large quantities of katkins (or male flowers,) though there are but three of them which have as yet produced cones; nor is it above thirty-five years that theſe have ripened their cones, ſo as to perfect the ſeed; but now the ſeeds which fall out of the cones on the ground near them, produce plants in plenty, which come up naturally without care: and ſince we find that they are ſo far naturalized to our country as to produce ripe ſeeds, we need not fear being ſoon ſupplied with enough, without depending on thoſe cones which are brought from the Levant; as there are many trees of this kind in England, which already do, and abundance more which in a few years muſt certainly bear: but I find they are more ſubject to produce and ripen their cones in hard winters than in mild ones; which is a plain indication, that they will ſucceed, even in the coldeſt parts of Scotland, where, as well as in England, they might be propagated to great advantage.

What we find mentioned in ſcripture of the lofty Cedars, can be no ways applicable to the ſtature of this tree; ſince, from the experience we have of thoſe now growing in England, as alſo from the teſtimony of ſeveral travellers, who have viſited thoſe few remaining trees on Mount Libanus, they are not inclined to grow very lofty, but, on the contrary, extend their branches very far; to which the alluſion made by the Pſalmiſt agrees very well, when he is deſcribing the flouriſhing ſtate of a people, and ſays, They ſhall ſpread their branches like the Cedar-tree.

Rauwolf, in his Travels, ſays, there were not at that time (i. e. anno 1574) upon Mount Libanus more than 26 trees remaining, 24 of which ſtood in a circle; and the other two, which ſtood at a ſmall diſtance, had their branches almoſt conſumed with age; nor could he find any younger trees coming up to ſucceed them, though he looked about diligently for ſome. Theſe trees (he ſays) were growing at the foot of a ſmall hill, on the top of the mountains, and amongſt the ſnow. Theſe having very large branches, commonly bend the tree to one ſide, but are extended to a great length, and in ſo delicate and pleaſant order, as if they were trimmed and made even with great diligence, by which they are eaſily diſtinguiſhed at a great diſtance from Fir-trees. The leaves (continues he) are very like to thoſe of the Larch-tree, growing cloſe together in little bunches upon ſmall brown ſhoots.

Maundrel in his Travels, ſays, there were but ſixteen large trees remaining when he viſited the mountains, ſome of which were of a prodigious bulk, but that there were many more young trees of a ſmaller ſize; he meaſured one of the largeſt, and found it to be 12 yards 6 inches in girt, and yet ſound, and 37 yards in the ſpread of its boughs. At about five or ſix yards from the ground it was divided into five limbs, each of which was equal to a great tree. What Maundrel hath related, was confirmed to me by a worthy gentleman of my acquaintance, who was there in the year 1720, with this difference only, viz. in the dimenſions of the branches of the largeſt tree, which he aſſured me he meaſured, and found to be twenty-two yards diameter. Now, whether Mr. Maundrel meant thirty-ſeven yards in circumference of the ſpreading branches, or the diameter of them, cannot be determined by his expreſſions, yet either of them well agrees with my friend's account.

Monſieur Le Brun reckons about 35 or 36 trees remaining upon Mount Libanus when he was there, and would perſuade us it was not eaſy to reckon their numbers (as is reported of our Stonehenge on Saliſbury Plain.) He alſo ſays, their cones do ſome of them grow dependent. Which is abundantly confuted by the above-mentioned travellers, as alſo from our own experience, for all the cones grow upon the upper part of the branches, and ſtand erect, having a ſtrong, woody, central ſtyle, by which it is firmly annexed to the branch, ſo as with difficulty to be taken off; which central ſtyle remains upon the branches after the cone is fallen to pieces, ſo that they never drop off whole, as the Pines do.

The wood of this famous tree is accounted proof againſt all putrefaction of animal bodies; the ſawduſt of it is thought to be one of the ſecrets uſed by thoſe mountebanks, who pretend to have the embalming myſtery. This wood is alſo ſaid to yield an oil, which is famous for preſerving books and writings; and the wood is thought by my Lord Bacon, to continue above a thouſand years ſound. It is alſo recorded, that in the temple of Apollo at Utica, there was found timber of near two thouſand years old. And the ſtatue of the goddeſs, in the famous Epheſian temple, was ſaid to be of this material alſo, as was moſt of the timber work of that glorious ſtructure.

This ſort of timber is very dry and ſubject to ſplit, nor does it well endure to be faſtened with nails, from which it uſually ſhrinks, therefore pins of the ſame wood are much preferable.

LARKSPUR. See **Delphinium.**

LASERPITIUM. Tourn. Inſt. R. H. 324. tab. 172. Lin. Gen. Plant. 306. Laſerwort.

The Characters are,

It hath an umbellated flower, compoſed of many ſmall umbels; both the ſmall and principal umbels have a many-leaved involucrum. The general umbel is uniform; the flowers have five equal petals, whoſe points are heart-ſhaped and inflexed; they have five ſtamina which are as long as the petals, terminated by ſingle ſummits; the roundiſh germen is ſituated under the flower, ſupporting two thick acuminated ſtyles, crowned by obtuſe ſpreading ſtigmas. The germen afterward becomes an oblong fruit with eight longitudinal wings or membranes, reſembling the fliers of a water-mill; the fruit divides into two parts, each containing one ſeed.

This genus of plants is ranged by Dr. Linnæus's in the ſecond ſection of his fifth claſs, intitled Pentandria Digynia, which includes thoſe plants whoſe flowers have five ſtamina and two ſtyles.

The Species are,

1. **Laserpitium** (*Commune*) foliolis oblongo-cordatis, inciſo-ſerratis. *Laſerwort with oblong heart-ſhaped lobes, which are cut like a ſaw.* Laſerpitium foliis latioribus lobatis. Mor. Umbel. 29. *Laſerwort with broader leaves, having lobes.*
2. **Laserpitium** (*Latifolium*) foliolis-cordatis inciſo-ſerratis. Hort. Cliff. 96. *Laſerwort with heart-ſhaped lobes cut like a ſaw.* Laſerpitium foliis amplioribus, ſemine criſpo. Inſt. R. H. 324. *Laſerwort with large leaves and curled ſeeds.*
3. **Laserpitium** (*Paludapifolium*) foliolis ovatis obtuſis acute ſerratis. *Laſerwort with oval obtuſe lobes ſharply ſawed.* Laſerpitium humilius, paludapii folio, flore albo. Inſt. R. H. *Lower Laſerwort, with a Smallage leaf and a white flower.*
4. **Laserpitium** (*Gallicum*) foliolis cuneiformibus furcatis. Lin. Sp. Plant. 248. *Laſerwort with wedge-ſhaped forked lobes.* Laſerpitium Gallicum. 156. C. B. P. *French Laſerwort.*
5. **Laserpitium** (*Anguſtifolium*) foliolis lanceolatis integerrimis ſeſſilibus. Hort. Cliff. 96. *Laſerwort with ſpear-ſhaped entire leaves ſitting cloſe to the branches.* Laſerpitium anguſtiſſimo & oblongo folio. Inſt. R. H. 324. *Laſerwort with a very narrow oblong leaf.*
6. **Laserpitium** (*Selinoides*) foliolis trifidis acutis. *Laſerwort with acute trifid lobes.* Laſerpitium ſelinoides, ſemine criſpo. Inſt. R. H. *Laſerwort reſembling ſweet Smallage, with a curled ſeed.*
7. **Laserpitium** (*Trilobum*) foliolis trilobis inciſis. Lin. Sp. 357. *Laſerwort with trifid leaves.* Libanotis latifolia aquilegiæ folio. C. B. P. 157.
8. **Laserpitium** (*Prutenicum*) foliolis lanceolatis integerrimis extimis coalitis. *Laſerwort with ſpear-ſhaped entire lobes, whoſe outer ones coaleſce.* Laſerpitium daucoides prutenicum viſcoſo ſemine. Breyn. Cent. 167.
9. **Laserpitium** (*Peucedanoides*) foliolis lineari-lanceolatis venoſo-ſtriatis diſtinctis Amœnit. Acad. 4. p. 310. *Laſerwort with linear ſpear-ſhaped leaves, which are diſtinct and veined.* Laſerpitium exoticum, lobis anguſtiſſimis integris. Pluk. Phyt. tab. 96. f. 2.
10. **Laserpitium** (*Siler*) foliolis ovato-lanceolatis integerrimis petiolatis. Hort. Cliff. 96. *Laſerwort with oval, ſpear-ſhaped, entire leaves, having foot-ſtalks.* Siler Montanum. Mor. Hiſt. 3. p. 276.
11. **Laserpitium** (*Chironium*) foliolis oblique cordatis, petiolis hirſutis. Lin. Sp. 358. *Laſerwort with oblique heart-ſhaped lobes, having hairy foot-ſtalks.* Panax Heracleum. Mor. Hiſt. 3. p. 315. *Herculus's All-heal.*
12. **Laserpitium** (*Ferulaceum*) foliolis linearibus. Lin. Sp. 358. *Laſerwort with linear leaves.* Cachrys Orientalis, ferulæ folio tenuiore, fructu alato plano. Tourn. Cor. 23.

There are ſome other varieties, if not diſtinct ſpecies of this plant; ſome of which have been put down as diſtinct ſpecies, which differ only in the colour of their flowers, therefore ſhould not be regarded as ſuch; but the number of ſpecies has been greatly leſſened by ſome late writers, who have erred as much in leſſening, as thoſe before them had done in multiplying of the ſpecies: which miſtake they may have fallen into by ſowing of the ſeeds near old plants of the ſame genus, or on ground where ſome of theſe ſorts have grown, ſo that their ſeeds have been ſcattered and buried in the ground, where they will remain two or three years, and afterward grow; ſo that unleſs their ſeeds are ſown at a diſtance from any of the other ſpecies, there will commonly ſome other ſpecies come up, whereby people have been often confuſed in diſtinguiſhing theſe plants; nay, I have frequently obſerved the ſeeds of one ſpecies fall, and the plants come up on the head of another plant which grew near it; and this young plant, if not timely rooted out, has gotten the better of the old plant, and deſtroyed it; therefore where there is not great care taken to prevent this, the different ſorts cannot be preſerved in gardens where the ſpecies grow near each other.

Theſe plants grow naturally in the ſouth of France, in Italy, and Germany, and are preſerved in botanic gardens for the ſake of variety; but as they have no great beauty, ſo are ſeldom cultivated in other gardens: they require much room, for their roots extend far every way, and the leaves of many ſorts will ſpread three feet, when the plants are ſtrong; their flower-ſtalks riſe four or five feet high, and their umbels of flowers are very large; they have all of them perennial roots but annual ſtalks. They flower in June, and the ſeeds ripen in September.

It is generally ſuppoſed, that the Silphium of the antients was procured from one ſpecies of this genus, but from which of them we are at preſent ignorant. All the ſpecies, if wounded, drop a very acrid juice, which turns to a reſinous gummy ſubſtance, very acrimonious. This was externally applied by the antients to take away black and blue ſpots that came by bruiſes and blows, as alſo to take away excreſcences; it was alſo by ſome of the antients preſcribed in internal medicines, but others have cautioned people not to make uſe of it this way, from the effects which they mention to have ſeen produced from the violence of its acrimony.

All theſe plants are extreme hardy, except the laſt, which requires a warmer ſituation, otherwiſe will be killed in ſharp winters; the other ſorts will thrive in moſt ſoils and ſituations; they are propagated by ſeed, which if ſown in autumn, the plants will come up the following ſpring; but when they are ſown in the ſpring, the ſeeds commonly remain in the ground a whole year. The plants ſhould be tranſplanted the following autumn where they are deſigned to remain, for they ſend out long deep roots, which are frequently broken by tranſplanting if they are large; when the plants are removed, they ſhould be planted three feet aſunder, for they grow very large; they decay to the ground every autumn, and come up again the following ſpring, but the roots will continue many years, and require no other culture but to clear them from weeds, and to dig between the roots every ſpring.

LATHYRUS. Tourn. Inſt. R. H. 394. tab. 216, 217. Lin. Gen. Plant. 781. Chichling Vetch; in French, *Geſſe*.

The CHARACTERS are,

The flower has a bell-ſhaped empalement of one leaf, cut into five parts at the top, the two upper being ſhort, and the under longer. The flower is of the butterfly kind. The ſtandard is heart-ſhaped, large, and reflexed at the point. The wings are oblong and blunt; the keel is half round, the ſize of the wings. It hath ten ſtamina, nine of them joined, and one ſeparate, crowned by roundiſh ſummits. It hath an oblong, narrow, compreſſed germen, ſupporting a riſing ſtyle, which is flat, and the upper part broad, with an acute point, crowned by a hairy ſtigma. The germen afterward becomes a long compreſſed pod, ending in a point, having two valves, and filled with roundiſh ſeeds.

This genus of plants is ranged in the third ſection of Linnæus's ſeventeenth claſs, intitled Diadelphia Decandria which includes thoſe plants whoſe flowers have ten ſtamina formed in two bodies.

The SPECIES are,

1. LATHYRUS (*Sativus*) pedunculis unifloris, cirrhis diphyllis, leguminibus ovatis compreſſis dorſo bimarginatis. Hort. Cliff. 367. *Chichling Vetch with one flower upon a foot-ſtalk, tendrils having two leaves, and oval compreſſed pods with two borders on their back part.* Lathyrus annuus, flore cæruleo, Ochri ſiliquâ. H. L. *Annual Chichling Vetch with a blue flower, and a pod like Ochrus.*
2. LATHYRUS (*Cicera*) pedunculis unifloris, cirrhis diphyllis, leguminibus ovatis compreſſis, dorſo canaliculatis. Lin. Sp. Plant. 730. *Chichling Vetch with one flower upon a foot-ſtalk, two-leaved tendrils, and an oval compreſſed pod a little channelled on the back.* Lathyrus ſativus flore purpureo. C. B. P. 344. *Cultivated Chichling Vetch with a purple flower.*
3. LATHYRUS (*Setifolius*) pedunculis unifloris, cirrhis diphyllis, foliolis ſetaceo-linearibus. Lin. Sp. 1031. *Chichling Vetch with one flower upon a foot-ſtalk, a two-leaved tendril, and linear briſtly lobes.* Lathyrus foliis anguſtis, floribus ſingularibus coccineis. Seg. Pl. Veron. *Chichling Vetch, with narrow leaves and ſingle ſcarlet flowers.*
4. LATHYRUS (*Pariſienſus*) pedunculis unifloris, cirrhis polyphyllis, ſtipulis lanceolatis. Hort. Cliff. 368. *Chichling Vetch with one flower upon a foot-ſtalk, a many-leaved tendril, and ſpear-ſhaped ſtipulæ.* Clymenum Pariſienſe flore cæruleo. Tourn. Inſt. R. H. 396. *Chichling Vetch of Paris with a blue flower.*
5. LATHYRUS (*Hiſpanicus*) pedunculis bifloris, cirrhis polyphyllis, foliolis alternis. Hort. Cliff. *Chichling Vetch with two flowers upon a foot-ſtalk, a many-leaved tendril, and the lobes placed alternate.* Clymenum Hiſpanicum, flore vario ſiliquâ articulatâ. Tourn. Inſt. R. H. 296. *Spaniſh Chichling Vetch, with a variable flower and jointed pod.*
6. LATHYRUS (*Odoratus*) pedunculis bifloris, cirrhis diphyllis, foliis ovato-oblongis, leguminibus hirſutis. Hort. Cliff. 368. *Chichling Vetch with two flowers on a foot-ſtalk, a two-leaved tendril, oblong oval leaves, and hairy pods.* Lathyrus diſtoplatyphyllos hirſutus, mollis, magno & peramæno flore odore. Hort. Cath. *The ſweet-ſcented Pea.*
7. LATHYRUS (*Hirſuta*) pedunculis bifloris, cirrhis diphyllis, foliolis lineari-lanceolatis, leguminibus hirſutis, ſeminibus ſcabris. Flor. Leyd. Prod. 363. *Chichling Vetch with two flowers on a foot-ſtalk, a two-leaved tendril, narrow ſpear-ſhaped lobes, hairy pods, and rough ſeeds.* Lathyrus anguſtifolius ſiliquâ hirſutâ. C. B. P. *Narrow-leaved Chichling Vetch with a hairy pod.*
8. LYTHYRUS (*Tingitanus*) pedunculis bifloris, cirrhis diphyllis foliolis alternis lanceolatis. Flor. Leyd. Prod. 263. *Chichling Vetch with two flowers on a foot-ſtalk, a two-leaved tendril, and ſpear-ſhaped alternate leaves.* Lathyrus Tingitanus ſiliquis orobi flore amplo ruberrimo. Mor. Hiſt. 2. 55. *Chichling Vetch of Tangier, with a bitter Vetch pod, and a large red flower.*
9. LATHYRUS (*Annuus*) pedunculis bifloris, cirrhis diphyllis, foliolis enſiformibus, leguminibus glabris, ſtipulis bipartitis. Amœn. Acad. 3. p. 417. *Chichling Vetch with two flowers on a foot-ſtalk, a two-leaved tendril, ſword-ſhaped lobes, ſmooth pods, and a bifid ſtipula.* Lathyrus luteus latifolius. Bot. Monſp. *Yellow broad-leaved Chichling Vetch.*
10. LATHYRUS (*Tuberoſus*) pedunculis multifloris, cirrhis diphyllis, foliolis ovalibus, internodis nudis. Hort. Cliff. 367. *Chichling Vetch with many flowers on a foot-ſtalk, a two-leaved tendril, oval leaves, and naked between the joints.* Lathyrus arvenſis repens tuberoſus. C. B. P. 344. *Creeping Field Chichling Vetch with a tuberous root.*
11. LATHYRUS (*Pratenſis*) pedunculis multifloris, cirrhis diphyllis, foliolis lanceolatis cirrhis ſimpliciſſimis. Hort. Cliff. 367. *Chichling Vetch with many flowers on a foot-ſtalk, a two-leaved tendril, ſpear-ſhaped leaves, and ſingle tendrils.* Lathyrus luteus ſylveſtris dumetorum. J. B. 2. p. 304. *Yellow wild Chichling Vetch of the woods.*
12. LATHYRUS (*Heterophyllus*) pedunculis multifloris, cirrhis diphyllis tetraphylliſque, foliolis lanceolatis. It. W. Goth. 75. *Chichling Vetch with many flowers on a foot-ſtalk, a two-leaved, and ſometimes four-leaved tendril, and ſpear-ſhaped leaves.* Lathyrus major Narbonenſis anguſtifolius. J. B. 2. 304. *Greater Chichling Vetch of Narbonne with narrow leaves.*
13. LATHYRUS (*Latifolius*) pedunculis multifloris, cirrhis diphyllis, foliolis lanceolatis, internodiis membranaceis. Hort. Cliff. 367. *Chichling Vetch with many flowers on a foot-ſtalk, a two-leaved tendril, ſpear-ſhaped leaves, and a membranaceous ſtalk between the joints.* Lathyrus latifolius. C. B. P. 344. *Broad-leaved Chichling Vetch, commonly called Everlaſting Pea.*
14. LATHYRUS (*Magnoflore*) pedunculis multifloris, cirrhis diphyllis foliolis ovato-lanceolatis, internodiis membranaceis. *Chichling Vetch with many flowers on a foot-ſtalk, a two-leaved tendril, oval ſpear-ſhaped leaves, and a membranaceous ſtalk between the joints.* Lathyrus latifolius minor flore majore. Boerh. Ind. alt. 2. p. 42. *Smaller broad-leaved Chichling Vetch with a larger flower, or large, red, flowering, Everlaſting Pea.*
15. LATHYRUS (*Piſiformis*) pedunculis multifloris, cirrhis polyphyllis, ſtipulis ovatis, baſi acutis. Hort. Upſal. 217. *Chichling Vetch with many flowers on a foot-ſtalk, a many-leaved tendril, and oval ſtipulæ acute at the baſe.*
16. LATHYRUS (*Niſſolia*) pedunculis unifloris, foliis ſimplicibus ſtipulis ſubulatis. Lin. Sp. Plant. 729. *Chichling Vetch with one flower on a foot-ſtalk, ſingle leaves, and awl-ſhaped ſtipulæ.* Niſſolia vulgaris. Tourn. Inſt. 656. *Crimſon Graſs Vetch.*
17. LATHYRUS (*Amphicarpos*) pedunculis unifloris calyce longioribus, cirrhis diphyllis ſimpliciſſimis ſubtus venoſis. *Chichling Vetch with ſingle flowers upon a foot-ſtalk, which are longer than the empalement, and a two-leaved ſingle tendril.*
18. LATHYRUS (*Aphaca*) pedunculis unifloris, cirrhis aphyllis, ſtipulis ſagitto-cordatis. Lin. Sp. 1029. *Chichling Vetch with one flower on each foot-ſtalk, a tendril without leaves, and a heart arrow-ſhaped ſtipula.* Aphacha. Lob. Ic. 2. p. 70.
19. LATHYRUS (*Americana*) pedunculis bifloris, foliis reniformibus ſimpliciſſimis ſubtus venoſis. *Chichling Vetch with two flowers upon a foot-ſtalk, and kidney-ſhaped ſingle leaves, which are veined on their under ſide.* Niſſolia Americana procumbens, folio rotundo, flore luteo. Houſt. MSS. *Trailing American Niſſolia, with a round leaf and a yellow flower.*

The firſt ſort grows naturally in France, Spain, and Italy; this is an annual plant, with a climbing ſtalk about two feet high. The leaves come out at each joint alternate; they are compoſed of two long narrow lobes, with a tendril or claſper riſing between, which faſtens to any ſupport near. The flowers come ſingly upon foot-ſtalks at each joint; they are blue, and ſhaped like thoſe of the Pea; theſe are ſucceeded by oval compreſſed pods, with a double membrane or wing running longitudinally on the back. This flowers in June and July, and the ſeeds ripen in September. It is ſeldom cultivated, unleſs in botanic gardens for the ſake of variety.

The ſecond ſort is cultivated in ſome countries for the ſeeds, which are uſed for feeding of poultry; this grows wild in Italy and Spain. It does not riſe ſo high as the firſt ſort. The leaves are longer, the pods are near twice the length of thoſe, and are channelled on their back ſide; this is cultivated in the ſame manner as Vetches or Tares.

The third ſort was ſent me from Verona, where it grows naturally; this is an annual plant, which ſeldom riſes more than ſix or eight inches high. The two lobes of the leaves are ſmall, and end with claſpers. The flowers are of a bright ſcarlet, and are ſucceeded by taper pods, filled with roundiſh ſeeds. This is only kept for variety in ſome botanic gardens.

The fourth ſort grows naturally about Paris; this is an annual plant, with a ſlender ſtalk about one foot high, garniſhed with leaves, compoſed of ſeveral narrow lobes placed alternate along the midrib, which end in claſpers. The flowers come out ſingly upon pretty long foot-ſtalks; they are blue, and about the ſize of thoſe of the common Tare. It grows naturally in ſome parts of England, particularly on Windſor foreſt, in moiſt meadows, and has often a variable flower.

The fifth ſort grows naturally in Spain and Italy; it is an annual plant, with a climbing ſtalk which riſes near three feet high, garniſhed with leaves compoſed of ſeveral lobes, which are ſpear-ſhaped, placed alternately along the midrib, which is terminated by very long claſpers. The foot-ſtalks of the flowers are five or ſix inches long, upon which ſtand two flowers one above the other, ſhaped like thoſe of the Pea. The ſtandard, which is large, is of a bright red colour, but the keel and wings are white. The flowers are ſucceeded by pretty long jointed pods, filled with roundiſh ſeeds. This flowers in June and July, and the ſeeds ripen in autumn.

The ſixth ſort is commonly known by the title of Sweet Pea; this grows naturally in Ceylon, but is hardy enough to thrive in the open air in England. It is an annual plant with a climbing ſtalk, which riſes from three to four feet high, garniſhed with leaves compoſed of two large oval lobes, whoſe midrib is terminated by long claſpers. The foot-ſtalks come out at the joints; they are about ſix inches long, and ſuſtain two large flowers with dark purple ſtandards; the keel and wings are of a light blue colour. The flowers have a ſtrong ſweet odour, and are ſucceeded by oblong inflated pods, which are hairy, containing four or five roundiſh ſeeds in each.

There are two other varieties of this ſort, one of which has a Pink-coloured ſtandard with a white keel, and the wings of a pale bluſh colour; this is commonly called Painted Lady Pea. The flowers of the other are all white, which are the only differences between them.

The ſeventh ſort grows naturally in Eſſex. I have found it in places which were ſpread over with Brambles, near Hockerel; this hath a perennial root, ſending out three or four weak ſtalks, which are near two feet long, garniſhed with leaves compoſed of two oblong lobes, whoſe midrib is terminated by claſpers. The foot-ſtalks are about four inches long, and ſuſtain two purple flowers, which are ſucceeded by rough hairy pods, little more than an inch long, containing three or four roundiſh ſeeds. This ſort is very rarely preſerved in gardens.

The eighth ſort was originally brought from Tangier to England; this is an annual plant, whoſe ſtalk riſes four or five feet high, garniſhed with leaves compoſed of two oval veined lobes, whoſe midrib ends with claſpers. The foot-ſtalks are ſhort, and ſuſtain two large flowers with purple ſtandards, whoſe wings and keel are of a bright red; theſe are ſucceeded by long jointed pods, containing ſeveral roundiſh ſeeds. This is ſometimes titled by the gardeners Scarlet Lupine.

The ninth ſort is an annual plant, which grows naturally about Montpelier. I have alſo received the ſeeds from Siberia; this riſes with a climbing ſtalk five or ſix feet high, which has two membranes, or wings, running along from joint to joint. The leaves are compoſed of two long narrow lobes, whoſe midrib ends with claſpers. The flowers ſtand upon long foot-ſtalks, each ſuſtaining two pale yellow flowers, which are ſucceeded by long taper pods, containing ſeveral roundiſh ſeeds.

The tenth ſort grows naturally amongſt the Corn in the South of France, and in Italy, but is cultivated in the Dutch gardens for the roots, which are there ſold in the markets, and are commonly eaten: this hath an irregular tuberous root about as big as thoſe of the Pignut, covered with a brown ſkin; theſe ſhoot up ſeveral weak trailing ſtalks, garniſhed with leaves compoſed of two oval lobes, ending with claſpers. The foot-ſtalks of the flowers are weak, about three inches long, each ſuſtaining two deep red flowers, which are ſeldom ſucceeded by pods, but the roots increaſe plentifully in the ground. This ſort will grow in moſt ſoils, but will thrive beſt on light ground.

The eleventh ſort grows naturally on the banks and under thickets in moſt parts of England; this hath a perennial creeping root, whereby it propagates ſo faſt as to be a very troubleſome weed, ſo ſhould not be admitted into gardens.

The twelfth ſort grows naturally by the ſide of hedges, and in thickets, in ſeveral parts of England; this hath a perennial creeping root, which ſends out many climbing ſtalks which riſe five or ſix feet high, garniſhed with leaves, which have ſometimes two, and at others four long narrow lobes, terminated by claſpers. The foot-ſtalks ſuſtain ſeveral ſmall flowers with pale ſtandards, whoſe wings and keels are blue; theſe are ſucceeded by long taper pods, containing ſeveral roundiſh ſeeds. It flowers in June and July, and the ſeeds ripen in autumn.

The thirteenth ſort has been found growing naturally in ſeveral parts of England, but is frequently cultivated in gardens for ornament, therefore it is doubtful if it is a native here; this hath a perennial root, from which ariſe ſeveral thick climbing ſtalks from ſix to eight feet high, which have membranaceous wings on each ſide between the joints. The leaves are compoſed of two ſpear-ſhaped lobes, and the midrib is terminated by claſpers. The foot-ſtalks are eight or nine inches long, and ſuſtain ſeveral large red flowers, which are ſucceeded by long taper pods, containing ſeveral roundiſh ſeeds. It flowers in June, July, and Auguſt, and the ſeeds ripen in autumn, ſoon after which the ſtalks die to the root, and new ones ariſe in the ſpring, from whence it is called Everlaſting Pea.

The fourteenth ſort differs from the laſt in the ſtalks, being much ſhorter and ſtronger. The leaves are broader, and of a deeper green. The flowers are much larger, and of a brighter red colour, ſo make a better appearance; theſe differences are laſting from ſeeds, for I have raiſed many plants from ſeeds within forty years paſt, and have always found them them to be the ſame as the parent plant.

The fifteenth ſort grows naturally in Siberia; this hath a perennial root and an annual ſtalk, which is garniſhed with leaves, compoſed of ſix or eight pair of oblong acute lobes. The flowers are blue, and many of them ſtand upon each foot-ſtalk; theſe are ſucceeded by pods, ſhaped like thoſe of the Pea. It flowers in June, and the ſeeds ripen in Auguſt.

The ſixteenth ſort grows naturally in moiſt meadows in many parts of England; this riſes with an upright ſtalk one foot high, which is garniſhed with long, narrow, ſingle leaves at each joint. The foot-ſtalks of the flowers come out from the joints toward the upper part of the ſtalk; they are ſlender, about three inches long, ſome having but one, and others have two bright red flowers on their tops. It flowers in May and June, and the ſeeds ripen in autumn. This is rarely kept in gardens.

The ſeventeenth ſort grows naturally in Syria; this is an annual plant with a trailing ſtalk, garniſhed with leaves compoſed of two lobes, whoſe midrib is terminated by a ſingle tendril. The foot-ſtalk ſupports one flower of a pale purple colour, and when the flowers decay, the germen is thruſt into the ground, where the pods are formed, and the ſeeds ripen.

The eighteenth ſort was diſcovered by the late Dr. Houſtoun, growing naturally at La Vera Cruz in New Spain; this is annual plant, with a trailing ſtalk a foot long, garniſhed with a ſingle kidney-ſhaped leaf at each joint. The flowers grow two together upon very ſhort foot-ſtalks; they are ſmall, and of a deep yellow colour; theſe are ſucceeded by ſhort taper pods, including three or four ſmall roundiſh ſeeds.

This ſort is tender, ſo the ſeeds ſhould be ſown upon a hot-bed in the ſpring, and when the plants are fit to remove, they ſhould be each planted into a ſmall pot filled with light earth, and plunged into a tan-bed, where they ſhould conſtantly remain, treating them in the ſame manner as other tender plants from warm countries; if they are brought forward in the ſpring, they will flower in July, and their ſeeds will ripen in autumn.

Several of the other ſorts are preſerved in curious gardens for the variety of their flowers, ſome of which make a fine appearance, and continue long in flower. Theſe may all be propagated by ſowing their ſeeds, either in ſpring or autumn; but thoſe which are ſowed in autumn ſhould have a light ſoil and a warm ſituation, where the plants will abide the winter, and come to flower early the following ſpring, and their ſeeds will ripen in July; but thoſe which are ſown in the ſpring ſhould have an open expoſure, and be planted upon almoſt any ſoil, if not too wet, for they are not tender plants, nor do they require much culture: theſe ſorts ſhould all of them be ſown where they are deſigned to remain, for they ſeldom ſucceed when they are tranſplanted, unleſs it is done while the plants are young; ſo that where they are ſown for ornament, there ſhould be four or five ſeeds ſown in a ſmall patch, in different parts of the borders of the flower-garden; and when the plants come up, they ſhould be carefully kept clear from weeds; but when they are grown two or three inches high, there ſhould be ſome ſticks put down by them to ſupport them, otherwiſe they will trail on the ground, or on whatever plants ſtand near them, and become unſightly.

The ſixth ſort, with the two varieties of it, are deſerving room in every good garden for the beauty and odour of their flowers; and the eighth ſort is by ſome cultivated for the colour of the flowers; but there are few of the other ſorts worthy of room in gardens, except the thirteenth and fourteenth ſorts, which, if they are planted in a proper ſituation, and are rightly trained, will make a fine appearance.

LATIFOLIOUS trees and plants are ſuch as have broad leaves.

LAVATERA. Tourn. Act. Gal. 1706. tab. 3. Dill. Gen. 10. Lin. Gen. Plant. 752.

The CHARACTERS are,

The flower has a double empalement; the outer is of one leaf, ſhort, obtuſe, and trifid; the inner is of one leaf, and quinquefid; they are both permanent. The flower hath five petals, which are joined at their baſe, plain, and ſpread open above. It has many ſtamina, which are joined in a column below, but above are looſe; they are inſerted in the petal, and terminated by kidney-ſhaped ſummits. It has an orbicular germen, ſupporting a ſhort cylindrical ſtyle, crowned by many briſtly ſtigmas. The empalement afterward becomes a fruit with ſeveral capſules, covered in front by a hollow ſhield, each capſule having one kidney-ſhaped ſeed.

This genus of plants is by Dr. Linnæus ranged in the fifth order of his ſixteenth claſs, intitled Monodelphia Polyandria, which includes thoſe plants whoſe flowers have many ſtamina joined in a column.

The SPECIES are,

1. LAVATERA (*Althææfolia*) foliis infimis cordato-orbiculatis, caulinis trilobis acuminatis glabris, pedunculis unifloris, caule herbaceo. *Lavatera whoſe lower leaves are orbicularly heart-ſhaped, thoſe on the ſtalks ſet with three acute ſmooth lobes, and one flower upon a foot-ſtalk, and an herbaceous ſtalk.* Lavatera folio & facie althææ. Act. R. P. 1706. *Lavatera with the leaves and appearance of Marſhmallow.*
2. LAVATERA (*Africana*) foliis infimis cordato-angulatis, supernè ſagittatis, pedunculis unifloris, caule herbaceo hirſuto. *Lavatera with the lower leaves angularly heart-ſhaped, the upper ones arrow-pointed, a ſingle flower upon each foot-ſtalk, and a hairy herbaceous ſtalk.* Lavatera Africana, flore pulcherrimo. Boerh. Ind. alt. *African Lavatera with a beautiful flower.*
3. LAVATERA (*Trimeſtris*) foliis glabris, caule ſcabro herbaceo, pedunculis unifloris, fructibus orbiculo tectis. Hort. nating the ſtalks. Althæa fruteſcens, folio bryoniæ. C. B. P. 316. *Shrubby Althæa with a Briony leaf.*

The firſt ſort grows naturally in Syria; it is an annual plant, with an erect, branching, herbaceous ſtalk, riſing two feet high; the under leaves are orbicularly heart-ſhaped, ſmooth, and ſtand upon long foot-ſtalks, the upper are divided into three acute lobes; the flowers come out upon long foot-ſtalks from the wings of the leaves; they are very large, and ſpread open like thoſe of the Marſhmallow, and are of a pale red or Roſe colour. Theſe come out in July, the ſeeds ripen in September, and the plants decay in autumn.

There is a variety of this with white flowers, which has accidentally riſen from ſeeds.

The ſecond ſort grows naturally at the Cape of Good Hope, from whence the ſeeds were brought to Holland, and the plants there cultivated, and the ſeeds have ſince been communicated to moſt parts of Europe. This differs from the firſt in the ſhape of the leaves, the lower having angles, and the upper being arrow-pointed; the ſtalks are hairy, the flowers larger, and of a brighter red colour.

This ſort is annual, and flowers at the ſame time with the former, and the ſeeds are ripe in the autumn.

The third ſort grows naturally in Spain and Sicily; this is an annual plant, which riſes with ſlender herbaceous ſtalks about two feet high, covered with a brown bark; the lower leaves are roundiſh, and the upper are angular, and ſome arrow-pointed. The flowers are not half ſo large as thoſe of either of the former, and are of a pale red colour; theſe ſtand upon ſhort foot-ſtalks, and appear about the ſame time with the former. This is certainly a diſtinct ſpecies, for I have cultivated it more than forty years, and I have never found it vary.

The fourth ſort hath a perennial root and an annual ſtalk, which riſes five or ſix feet high, is woolly, garniſhed with angular heart-ſhaped leaves, ſtanding upon long foot-ſtalks. The flowers come out from the wings of the leaves toward the top, ſitting cloſe to the ſtalks at every joint; they are of a purpliſh colour, and ſhaped like thoſe of the Marſhmallow, but are larger. Theſe appear in July and Auguſt, and the ſeeds ripen in the autumn, then the ſtalks decay to the root. It grows naturally in Auſtria and Bohemia.

The fifth ſort grows naturally at the Cape of Good Hope, the ſeeds of it were ſent me by the ingenious Mr. Storm, gardener at Amſterdam. This riſes with a ſhrubby branching ſtalk to the height of eight or ten feet, garniſhed with large hairy leaves, deeply divided into five roundiſh lobes, which are indented on their edges, of a bright green, ſtanding alternately upon long foot-ſtalks; as the plants become more ſhrubby the leaves decreaſe in ſize, ſo that the upper leaves are not more than a ſixth part of the bigneſs of the firſt or lower leaves. The flowers come out ſingly at the wings of the leaves at every joint, ſo that as the branches extend there is a ſucceſſion of flowers, whereby the plants are ſeldom deſtitute of them the whole year. The flowers are of a bright purple colour, but are not very large; theſe are ſucceeded by capſules having many partitions, in each of theſe is one kidney-ſhaped ſeed, which ripen in ſucceſſion as the flowers are produced.

The ſixth ſort is commonly called Mallow-tree; this riſes with a very ſtrong thick ſtalk the height of eight or ten feet, dividing into many branches at the top, which are garniſhed with ſoft woolly leaves that are plaited, and the edges cut into ſeveral angles. The flowers are produced in cluſters at the wings of the leaves, each ſtanding upon a ſeparate foot-ſtalk; they are of a purple colour, and ſhaped like thoſe of the common Mallow, and are ſucceeded by ſeeds of the ſame form. This ſort flowers from June to September, and the ſeeds are ripe in the autumn.

The ſeventh ſort riſes with a ſhrubby ſtalk ſeven or eight feet high, ſending out ſeveral long branches, garniſhed with woolly leaves, differing greatly in ſize and ſhape, the lower being partly heart-ſhaped at their baſe, but divide into five roundiſh lobes; the upper, which are ſmall, have three lobes, which are indented on their edges. The flowers come out from the wings of the ſtalk, three or four at each joint, upon very ſhort foot-ſtalks; they are of a light purple colour, and ſhaped like thoſe of Marſhmallow. There is a ſucceſſion of theſe flowers from June to the autumn.

The eighth ſort is a ſhrub which grows to the ſame ſize as the ſeventh, and differs from it in the ſhape of the leaves, which are divided into three or five acute-pointed lobes; the flowers are ſmaller, but of the ſame ſhape and colour, it continues in flower at the ſame time. This grows naturally in the ſouth of France.

The ninth ſort riſes with a ſhrubby ſtalk ſix or eight feet high, ſending out many branches, garniſhed with roundiſh, crenated, woolly leaves, ſtanding upon long foot-ſtalks; the foot-ſtalks of the flowers come out in cluſters from the wings of the leaves, each ſuſtaining one large pale blue flower, of the ſame ſhape with thoſe of the other ſpecies. This flowers at the ſame time with them, and the ſeeds ripen in the autumn.

The tenth ſort hath a ſoft, ſhrubby, woolly ſtalk, which riſes to the height of four or five feet; theſe ſtand more erect than either of the former ſorts, and do not branch ſo much; the leaves are heart-ſhaped at their baſe, but round on their edges, very hoary and waved, ſtanding upon long foot-ſtalks. The flowers come out in cluſters from the wings of the leaves, ſtanding upon foot-ſtalks of different lengths; theſe generally ſupport but one flower, but ſometimes they have two or three; the flowers are large, and of a pale blue colour. They appear at the ſame time with the former, and their ſeeds ripen in the autumn. It grows naturally in Portugal.

The eleventh ſort riſes with a ſhrubby ſtalk ſix or ſeven feet high, ſending out ſeveral ſhrubby branches, which are garniſhed with woolly leaves, divided into five lobes, which end in acute points, and are crenated on their edges; the lower part of the branches are adorned with a ſingle flower at each joint, ſitting cloſe to the ſtalk, but the branches are terminated by looſe ſpikes of flowers, which are of a pale blue colour, and ſhaped like thoſe of the former.

The ſix laſt mentioned ſorts, though they have ſhrubby ſtalks, yet are but of ſhort duration here; the ſixth, tenth, and eleventh ſorts, ſeldom continue longer than two years, unleſs when they happen to grow upon dry rubbiſh, where they make but little progreſs, and their ſtalks and branches being firmer, ſo are better able to reſiſt the cold; for when they are in good ground, they are very vigorous and full of ſap, ſo are killed by the froſt in common winters. The other three ſorts are not quite ſo tender, nor of ſo ſhort duration; theſe will continue three or four years, and ſometimes longer, provided the winters are not very ſevere; or if the plants ſtand in a warm ſituation and on a dry ſoil, but in moiſt rich ground they ſeldom continue long.

All theſe ſhrubby ſorts are eaſily propagated by ſeeds, which ſhould be ſown in the ſpring upon a bed of light earth; and when the plants are about three or four inches high, they ſhould be tranſplanted to the places where they are deſigned to remain; for as they ſhoot out long fleſhy roots which have but few fibres, ſo they do not ſucceed well if they are tranſplanted after they are grown large. If the ſeeds of theſe plants are permitted to ſcatter on the ground, the plants will come up the following ſpring; and when they happen to fall into dry rubbiſh, and are permitted to grow therein, they will be ſhort, ſtrong, woody, and produce a greater number of flowers than thoſe plants which are more luxuriant. As theſe plants continue a long time in flower, ſo a few plants of each ſort may be allowed a place in all gardens where there is room.

The three firſt ſorts are annual plants, which are propagated by ſeeds: the ſeaſon for ſowing them is the end of March or the beginning of April, upon a bed of freſh light earth; and when the plants are come up, you muſt carefully clear them from weeds; and in very dry weather they muſt be now and then refreſhed with water. When they are about two inches high, you muſt tranſplant them into the places where they are deſigned to remain, which ſhould be in the middle of the borders in the flower-garden; for if the ſoil is good, they will grow two or three feet high; in tranſplanting them, you muſt take them up very carefully, preſerving a ball of earth to their roots, otherwiſe they are apt to miſcarry; and alſo water and ſhade them until they have taken root, after which they will require no other care but to clear them from weeds, and to faſten them to ſtakes, to prevent their being injured by ſtrong winds. You may alſo ſow their ſeeds in autumn, and when the plants are come up, tranſplant them into ſmall pots, which, towards the end of October, ſhould be placed in a common hot-bed frame, where the plants being defended from ſevere froſts, will abide the winter very well; and in the ſpring, you may ſhake them out of the pots, and plant them into larger, or elſe into the full ground, where they may remain to flower. The plants thus managed will be larger, and flower ſtronger and earlier than thoſe ſown in the ſpring, and from theſe you will conſtantly have good ſeeds, whereas thoſe ſown in the ſpring ſometimes miſcarry. The ſeeds of the third ſort ſhould be ſown in the ſpring in the place where they are to remain, for they do not well bear removing in the ſummer.

The two firſt ſorts are very ornamental plants in a fine garden, when placed among other annuals, either in pots or borders.

The fourth ſort hath a perennial root which abides ſeveral years, but the ſtalks decay in the autumn, and new ones ariſe in the ſpring. This is propagated by ſeeds, which ſhould be ſown upon a bed of light earth in the ſpring, and when the plants are fit to remove, they ſhould be either tranſplanted to the places where they are to remain, or into pots where they may ſtand to get more ſtrength, before they are planted in the full ground. After the plants are well rooted, they will require no other care but to keep them clear from weeds. And if the winter ſhould prove very ſevere, it will be proper to cover the ground about them with old tanners bark to keep out the froſt; but they will endure the cold of our ordinary winters very well, and will produce their flowers and ripen their ſeeds annually.

The fifth ſort will not live through the winter in the open air in England, ſo the ſeeds ſhould be ſown in the ſame manner as thoſe of the other ſorts; and when the plants are fit to remove, they ſhould be each planted into a ſmall pot filled with light earth, and placed in the ſhade till they have taken new root; then they may be removed to a ſheltered ſituation, and mixed with other hardy exotic plants. As the plants advance in their growth, ſo they will require larger pots, and muſt be treated in the ſame way as other exotic plants; in the autumn they muſt be removed into the green-houſe, and placed with Myrtles and the other kinds of plants, which only require protection from hard froſt, but muſt have as much free air as poſſible in mild weather.

LAVENDULA. Tourn. Inſt. R. H. 198. tab. 93. Lin. Gen. Plant. 630. Lavender; in French, *Lavende*. [It takes its name of Lavando, *Lat.* waſhing, becauſe it was uſed to be thrown into baths for the fragrancy of the ſcent; or becauſe uſed in lye, to give a fragrancy to linen; and becauſe it is very good to waſh the face with, and give it both beauty and a grateful ſcent.]

The Characters are,

The flower hath an oval permanent empalement of one leaf, which is obſcurely indented at the brim. The flower is of the lip kind, with one petal, having a cylindrical tube longer than the empalement, but ſpreading above; the upper lip is large, bifid, and open; the under lip is cut into three equal ſegments. It hath four ſhort ſtamina ſituated within the tube of the petal, two being ſhorter than the other, terminated by ſmall ſummits. It hath a germen divided in four parts, ſupporting a ſlender ſtyle the length of the tube, crowned by an obtuſe indented ſtigma. The germen afterward turns to four oval ſeeds, ſitting in the empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's fourteenth claſs, intitled Didynamia Gymnoſpermia, which includes thoſe plants whoſe flowers have two ſhort and two longer ſtamina, and have four naked ſeeds ſitting in the empalement.

The Species are,

1. Lavendula (*Spica*) foliis lanceolatis integerrimis ſpicis nudis. Hort. Cliff. 303. *Lavender with entire ſpear-ſhaped leaves and naked ſpikes.* Lavendula latifolia. C. B. P. 216. *Broad-leaved Lavender.*
2. Lavendula (*Anguſtifolia*) foliis lanceolato-linearibus, ſpicis nudis. *Lavender with ſpear-ſhaped narrow leaves, and naked ſpikes.* Lavendula anguſtifolia. C. B. P. 216. *Narrow-leaved Lavender.*
3. Lavendula (*Multifida*) foliis duplicato-pinnatifidis. Vir. Cliff. 56. *Lavender with leaves doubly wing-pointed.* Lavendula folio diſſecto. C. B. P. 216. *Lavender with a cut leaf.*
4. Lavendula (*Canarienſis*) foliis duplicato-pinnatifidis hirſutis, ſpicis faſciculatis. *Lavender with doubly wing-pointed hairy leaves, and ſpikes of flowers growing in cluſters.* Lavendula folio longiore tenuius & elegantius diſſecto. Tourn. Inſt. R. H. 198. *Lavender with a longer, narrower, and more elegant cut leaf.*

The firſt ſort is cultivated in ſeveral of the Engliſh gardens, and has been generally known by the title of Spike, or Lavender Spike; the leaves of this ſort are much ſhorter and broader than thoſe of the common Lavender, and the branches are ſhorter, more compact, and fuller of leaves. This ſort doth not often produce flowers, but when it does, the flower-ſtalks are garniſhed with leaves very different from thoſe on the other branches, approaching nearer to thoſe of the common ſort, but are broader; the ſtalks grow taller, the ſpikes of the flowers are larger, the flowers are ſmaller, and are in looſer ſpikes. It generally flowers a little later in the ſeaſon. This has been frequently confounded with the common Lavender, and has been ſuppoſed the ſame ſpecies, but is undoubtedly a different plant.

This I believe to be the ſame with what Dr. Moriſſon calls Lavendula latifolia ſterilis, for the plants will continue ſeveral years without producing flowers; during which time they have a very different appearance from thoſe of the common Lavender, as thoſe branches of the ſame plant always have which do not flower; but I have planted ſlips taken from thoſe flowering branches with narrow leaves, and others from thoſe with the broad leaves, but have always found the plants ſo propagated return to their original ſort, the cuttings with the narrow leaves have become broad again.

The ſecond ſort is the common Lavender, which is ſo well known as to require no deſcription. Both theſe ſorts flower in July, at which time the ſpikes of the ſecond ſort are gathered for uſe; there is a variety of this with white flowers.

Theſe are propagated by cuttings or ſlips; the beſt ſeaſon for which is in March, when they ſhould be planted in a ſhady ſituation, or at leaſt they ſhould be ſhaded with mats until they have taken root, after which they may be expoſed to the ſun; and when they have obtained ſtrength, may be removed to the places where they are deſigned to remain. Theſe plants will abide much longer in a dry, gravelly, or ſtony ſoil, in which they will endure our ſevereſt winters; though they will grow much faſter in the ſummer, if they are planted upon a rich, light, moiſt ſoil, but then they are generally deſtroyed in winter; nor are the plants half ſo ſtrong ſcented, or fit for medicinal uſes, as thoſe which grow upon the moſt barren rocky ſoil.

Theſe plants were formerly in uſe to make edgings to borders in gardens, for which purpoſe they are by no means proper, for they will grow too large for ſuch deſigns; and if they are often cut in very dry weather, they are ſubject to decay; and in hard winters they are very often killed, ſo that the edging will not be complete: beſides, theſe plants greatly exhauſt the goodneſs of the ſoil, whereby the plants in the borders will be deprived of their nouriſhment; ſo that they ſhould never be planted in a fine garden amongſt other choice plants and flowers, but rather be placed in beds in the phyſic-garden, or in any part of the kitchen-garden, if the ſoil is dry.

The third ſort grows naturally in Andaluſia; this is an annual plant, which riſes with an upright branching ſtalk two feet high; the ſtalks are woolly, and garniſhed with hoary leaves growing oppoſite, which are cut into many diviſions to the midrib; theſe ſegments are again divided on their borders toward the top, into three obtuſe ſegments, ſo that they end in many points. The foot-ſtalk of the flower is continued from the end of the branches, which is naked, and about ſix inches long, having four corners or angles, and is terminated by a cloſe ſpike of flowers about one inch long; the ſpike has the rows of flowers twiſted ſpirally: under this ſpike there are commonly two ſmall ones proceeding from the ſide of the ſtalk, at about an inch diſtance from the middle ſpike. This ſort flowers in July, and the ſeeds ripen in autumn. There are two varieties of this, one with blue, and the other with white flowers.

This ſort is ſown every ſpring on borders or beds of light freſh earth, and when the plants come up, they may be tranſplanted into other borders of the flower-garden, or into pots, to remain for good; where they will require no farther care, but to keep them clean from weeds. Theſe are pretty plants to place in large borders, amongſt other plants, for variety, but they are never uſed with us; they may alſo be preſerved over the winter, if placed in a green-houſe in autumn; but they never continue longer than two years with us, and many times (if they have produced ſeeds the firſt year) they will not continue longer. Nor do thoſe plants which are thus preſerved, appear handſome the following ſummer, ſo that, unleſs in bad ſeaſons, when the ſeeds do not ripen in the open air, it is not worth while to preſerve the plants. If the ſeeds of this ſort are permitted to ſcatter, the plants will come up the following ſpring without care, and may be treated in the manner before directed.

The fourth ſort grows naturally in the Canary Iſlands, from whence the ſeeds were ſent to the Biſhop of London, which were ſown in his Lordſhip's garden at Fulham, where this plant was firſt raiſed. This riſes with an upright, branching, ſquare ſtalk four feet high, garniſhed with leaves which are longer, and cut into narrower ſegments than thoſe of the third ſort. They are of a lighter green and almoſt ſmooth; the naked flower-ſtalk is alſo much longer than thoſe of the former, and terminated with a cluſter of ſpikes of blue flowers; at two or three inches below theſe, are two ſmall ſpikes of flowers, ſtanding one on each ſide the ſtalk. The flowers are ſmaller than thoſe of the common Lavender, but are of the ſame ſhape.

This ſort is tenderer than either of the former, ſo the ſeeds of this muſt be ſown on a moderate hot-bed in the ſpring; and when the plants come up, they ſhould be each planted into a ſeparate ſmall pot filled with light earth, and plunged into another hot-bed, to bring the plants forward; and in the beginning of June, they ſhould be inured to the open air, when they ſhould be placed in a ſheltered ſituation toward the end of that month; in July the plants will flower, and if the autumn proves warm, the ſeeds will ripen in September; but when they do not perfect ſeeds, the plants may be preſerved through the winter in a good green-houſe, where they will produce flowers moſt part of that ſeaſon, whereby good ſeeds may be obtained.

LAUREOLA. See Thymelæa.

LAUROCERASUS. See Padus.

LAURUS. Tourn. Inſt. R. H. 597. tab. 367. Lin. Gen. Plant. 452. The Bay-tree; in French, *Laurier*.

The Characters are,

It hath male and hermaphrodite flowers on different plants, the male flowers have no empalement: they have one petal, which is cut into ſix ſegments at the top, and nine ſtamina which are ſhorter than the petal, ſtanding by threes, terminated by ſlender ſummits. The hermaphrodite flowers have no empalement; they have one petal, which is ſlightly cut into ſix ſegments at the top. In the bottom is ſituated an oval germen, ſupporting a ſingle ſtyle of the ſame length with the petal, crowned by an obtuſe ſtigma, attended by ſix or eight ſtamina: there are two globular glands, ſtanding upon very ſhort foot-ſtalks, fixed to the baſe of the petal. The germen afterward becomes an oval berry with one cell, incloſing one ſeed of the ſame form.

This genus of plants is ranged in the firſt ſection of Linnæus's ninth claſs, intitled Enneandria Monogynia, which includes thoſe plants whoſe flowers have nine ſtamina and one ſtyle; but it ſhould be ranged in his twenty-ſecond claſs, which includes thoſe plants whoſe male and female flowers are upon different plants.

The Species are,

1. Laurus (*Nobilis*) foliis lanceolatis venoſis perennantibus, floribus quadrifidis diœciis. Hort. Cliff. 105. *Bay-tree with evergreen, ſpear-ſhaped, veined leaves, and flowers cut into four points, which are male and female on different plants.* Laurus latifolia Diſcoridis. C. B. P. *The broad-leaved Bay of Dioſcorides.*

13. Laurus (*Perſea*) foliis venoſis ovatis coriaceis perennantibus, floribus corymboſis. Lin. Sp. 529. *Bay-tree with oval, thick, veined leaves, which continue through the year, and flowers growing in a corymbus.* Perſea. Cluſ. Hiſt. 1. p. 2.

The firſt ſort is the broad-leaved Bay, which grows naturally in Aſia, Spain and Italy; from all thoſe places I have received the berries ſeveral times. This is almoſt too tender to thrive in the open air in England, for in ſevere winters they are frequently killed, or their branches are ſo much injured as to appear ſo for a long time; therefore they are generally planted in tubs, and removed into the green-houſe in winter. The leaves of this ſort are much broader than thoſe of the common Bay, and are ſmoother: there are male and female plants of this, as there are alſo of all the other ſorts.

The ſecond is the common Bay; of this there are plants with plain leaves, and others which are waved on their edges, but they ſeem to be the ſame ſpecies; for the young plants which I have raiſed from the berries of one, have been a mixture of both ſorts; but this is undoubtedly a different ſpecies from the firſt, for this ſort thrives well in the open air, and is ſeldom hurt, except in very ſevere winters; whereas the firſt will ſcarce live abroad, while young, in common winters, without ſhelter.

The third ſort hath very long narrow leaves which are not ſo thick as thoſe of the two former, and are of a light green; the branches are covered with a purpliſh bark, and the male flowers come out in ſmall cluſters from the wings of the leaves ſitting cloſe to the branches. This ſort is too tender to thrive in the open air in England, ſo the plants are generally kept in pots or tubs, and houſed in winter as the firſt ſort.

The fourth ſort grows naturally at Madeira and the Canary Iſlands, from whence it was formerly brought to Portugal, where it has been propagated in ſo great plenty, as to appear now as if it was a native of that country. In the year 1620, this plant was raiſed in the Farneſian garden, from berries which were brought from India, and was ſuppoſed to be a baſtard ſort of Cinnamon. This grows to the height of thirty or forty feet in temperate countries, but it is too tender to thrive in the open air in England, ſo the plants are kept in pots and tubs, and removed into the green-houſe in winter.

The leaves of this ſort are much larger than thoſe of the common Laurel; they are thick, ſmooth, and of a light green, the foot-ſtalks inclining to red; the branches are regularly diſpoſed on every ſide, and the male flowers are diſpoſed in long bunches; they are of a whitiſh green colour; the berries are much larger than thoſe of the other ſorts. It is called by ſome the Royal Bay, and by others the Portugal Bay.

The fifth ſort grows naturally in Carolina in great abundance, where it is called the Red Bay; it alſo is found in ſome other parts of America, but not in ſo great plenty. In ſome ſituations near the ſea, this riſes with a ſtrait trunk to a conſiderable height, and their ſtems are large, but in the inland parts of the country they are of an humbler ſtature. The wood of this tree is much eſteemed, being of a fine grain, ſo is of excellent uſe for cabinets, &c.

The leaves of this ſort are much longer than thoſe of the common Bay, and are a little woolly on their under ſide, their edges are a little reflexed; the veins run tranſverſly from the midrib to the ſides, and the male flowers come out in long bunches from the wings of the leaves. The female trees produce their flowers in looſe bunches, ſtanding upon pretty long foot-ſtalks, which are red; theſe are ſucceeded by blue berries ſitting in red cups.

This ſort is alſo too tender to thrive in the open air in England; for although ſome plants have lived abroad in a mild winter, which were planted in a warm ſituation, yet the firſt ſharp winter has deſtroyed them, ſo that theſe plants muſt be kept in pots or tubs, and houſed in winter like the former.

Theſe five ſorts may be propagated by layers, and the common ſort is generally propagated by ſuckers; but thoſe plants never keep to one ſtem, but generally ſend out a great number of ſuckers from their roots, and form a thicket, but do not advance in height; therefore the beſt way to have good plants, is to raiſe them from the berries, when they can be procured, for the plants which come from ſeeds, always grow larger than the others, and do not put out ſuckers from their roots, ſo may be trained up with regular ſtems. The beſt way is to ſow the berries in pots, and plunge them into a moderate hot-bed, which will bring up the plants much ſooner than if they are ſown in the full ground, ſo they will have a longer time to get ſtrength before winter; but the plants muſt not be forced with heat, therefore they ſhould be inured to bear the open air the beginning of June, into which they ſhould be removed, where they may remain till autumn; then the pots ſhould be placed under a common frame, that the plants may be protected from hard froſt, but in mild weather they may enjoy the free air; for while the plants are ſo young, they are in danger of ſuffering in hard froſt, even the common ſort of Bay. The ſpring following, thoſe ſorts which will not live in the open air, ſhould be each tranſplanted into ſeparate pots; but the common ſort may be planted in nurſery-beds ſix inches aſunder each way, where they may grow two years, by which time they will be fit to plant where they are deſigned to grow. The other ſorts muſt be conſtantly kept in pots, ſo ſhould every year be new potted, and as they advance in growth, they muſt have larger pots. As theſe plants require ſhelter in winter, a few of each ſort will be enough for a large green-houſe.

The common Bay will make a variety in all evergreen plantations; and as it will grow under the ſhade of other trees, where they are not too cloſe, ſo it is very proper to plant in the borders of woods, where it will have a good effect in winter.

The ſixth ſort grows naturally in North America, where it riſes to the height of ten or twelve feet, dividing into many branches, garniſhed with oval ſpear-ſhaped leaves near three inches long, and one inch and a half broad, ſmooth on their upper ſurface, but with many tranſverſe veins on their under ſide; theſe leaves fall off in the autumn like other deciduous trees. The flowers I have but once ſeen, thoſe were all male, and of a white herbaceous colour; but if I remember right, they had but ſix ſtamina in each.

The Saſſafras-tree is alſo very common in moſt parts of North America, where it ſpreads greatly by its roots, ſo as to fill the ground with ſuckers wherever they are permitted to grow; but in England this ſhrub is with difficulty propagated. In America it is only a ſhrub, ſeldom riſing more than eight or ten feet high; the branches are garniſhed with leaves of different ſhapes and ſizes, ſome them are oval and entire, about four inches long and three broad; others are deeply divided into three lobes; theſe are ſix inches long, and as much in breadth from the extremity of the two outſide lobes; they are placed alternately upon pretty long foot-ſtalks, and are of a lucid green; theſe fall off in the autumn, and in the ſpring, ſoon after the leaves begin to come out, the flowers appear juſt below them, upon ſlender foot-ſtalks, each ſuſtaining three or four ſmall yellow flowers, which have five oval concave petals, and eight ſtamina in the male flowers, which are upon different plants from the hermaphrodite flowers, which have an oval germen, that afterward becomes an oval berry, which, when ripe, is blue, but thoſe plants do not produce fruit in England.

The eighth ſort grows naturally in North America, in ſwampy lands; this riſes with a ſhrubby branching ſtalk eight or ten feet high, covered with a purple bark. The leaves are placed oppoſite, and are near two inches long and one broad, ſmooth on their upper ſide, but are veined on their under, where they are rough. This hath not as yet produced flowers here, but the berries which were ſent me from Maryland were red, and nearly the ſize and ſhape of the common Bay-berry.

The Camphire-tree grows naturally in Japan, and in ſeveral parts of India, and alſo at the Cape of Good Hope, where it riſes to a tree of middling ſtature, dividing into many ſmall branches, garniſhed with oval ſpear-ſhaped leaves, ſmooth on their upper ſide, having three longitudinal veins which unite above the baſe; if theſe are bruiſed, they emit a ſtrong odour of Camphire, as alſo the branches when broken. Theſe are male and hermaphrodite on different trees; I have only ſeen thoſe of the male, which has flowered plentifully in England; theſe were ſmall, and compoſed of five concave yellow petals, very like thoſe of the Saſſafras-tree, and were produced three or four upon each foot-ſtalk, in like manner.

The tenth ſort was diſcovered by the late Dr. Houſtoun at La Vera Cruz; this riſes with a woody ſtalk to the height of twenty feet, dividing into many branches, which are covered with a gray rough bark; at the extremity of the branches are produced the foot-ſtalks, which are unequal in length, but divide into ſeveral ſmaller, each ſuſtaining a cluſter of ſmall white flowers, which are collected into a head or ſmall umbel, having one general involucrum; theſe are male and hermaphrodite on different trees. The hermaphrodite flowers are ſucceeded by oval berries, not quite ſo large as thoſe of the common Bay. The leaves of this tree are about two inches long and one broad, rounded at the top and entire, ſtanding upon very ſhort foot-ſtalks.

The Saſſafras-tree is commonly propagated by the berries, which are brought from America; but theſe berries generally lie in the ground a whole year, and ſometimes two or three years before they grow, when they are ſown in the ſpring; therefore the ſureſt method of obtaining the plants will be, to get the berries put into a tub of earth ſoon after they are ripe, and ſent over in the earth; and as ſoon as they arrive, to ſow the berries on a bed of light ground, putting them two inches in the earth; and if the ſpring ſhould prove dry, the bed muſt be frequently watered, and ſhaded from the great heat of the ſun in the middle of the day; with this management many of the plants will come up the firſt ſeaſon, but as a great many of the berries will lie in the ground till the next ſpring, ſo the bed ſhould not be diſturbed, but wait until the ſeaſon after, to ſee what will come up. The firſt winter after the plants come up, they ſhould be protected from the froſt, eſpecially in the autumn; for the firſt early froſt at that ſeaſon is apt to pinch the ſhoots of theſe plants, which, when young, are tender and full of ſap, ſo will do them more injury than the ſevere froſt of the winter; for when the extreme part of the ſhoots are killed, it greatly affects the whole plant.

When the plants have grown a year in the ſeed-bed, they may be tranſplanted into a nurſery, where they may ſtand one or two years to get ſtrength, and may then be tranſplanted into the places where they are to remain for good.

There have been ſome of theſe plants propagated by layers, but theſe are commonly two, and ſometimes three years before they put out roots; and if they are not duly watered in dry weather, they rarely take root; ſo that it is uncertain, whether one in three of theſe layers do ſucceed, which makes theſe plants very ſcarce in England at preſent.

The wood of this ſhrub is frequently uſed to make tea, which is eſteemed a great antiſcorbutic; and in Carolina they frequently give a decoction of the wood and leaves in intermitting fevers; but the flowers of the ſhrub are gathered, and dried by the moſt curious, and are uſed for tea.

The Benjamin-tree, as it is falſly called, may be propagated in the ſame manner as the Saſſafras, by ſowing of the berries: theſe generally lie long in the ground, ſo that unleſs they are brought over in earth, in the ſame way as before directed, they often fail, or at leaſt remain long in the ground; but this is now frequently propagated by layers in England, which put out roots pretty freely, when the young ſhoots are choſen to make layers.

The eighth ſort is alſo a native of the ſame country with the laſt, and may be propagated by ſeeds in the ſame manner as thoſe, and require the ſame treatment. This may alſo be propagated by layers, which put out roots pretty freely; and as the ſhrubs do not produce ſeeds in England, ſo this is the beſt method to propagate them.

Theſe three ſorts will live in the open air in England, but the Saſſafras is often injured by very ſevere froſts, eſpecially if they are in an expoſed ſituation; therefore theſe plants ſhould have a warm ſituation and a looſe ſoil; and in moiſt ground this, and alſo the eighth ſort, will thrive much better than in a dry ſoil; for when they are planted on a hot gravelly ſoil, they frequently die in ſummer when the ſeaſon proves dry. They are all of them now much cultivated in England, to add to the variety of ſhrubs, but they are not very ornamental plants; though indeed the Saſſafras makes a good appearance in ſummer, when it is fully clothed with its large leaves, which being of different ſhapes, makes an agreeable variety, when intermixed with ſhrubs of the ſame growth.

The Camphire-tree is very near a-kin to the Cinnamon-tree, from which it differs in the leaves, thoſe of the Cinnamon-tree having three ribs running longitudinally from the foot-ſtalk to the point, where they ſoon diminiſh; whereas the ribs of the leaves of this tree are ſmall, and extend toward the ſides, and have a ſmooth ſhining ſurface: they are both male and hermaphrodite in different trees.

In Europe this tree is propagated by layers, which are generally two years, and ſometimes longer, before they take root, ſo that the plants are very ſcarce; and as all thoſe which I have ſeen flower are male trees, ſo there can be no hopes of procuring ſeeds from them here: but if the berries of this, and alſo of the Cinnamon-tree, were procured from the places of their growth, and planted in tubs of earth, as hath been directed for the Saſſafras-tree, there may be a number of theſe plants procured in England: and if they were ſent to the Britiſh colonies in America, they might be there cultivated, ſo as to become a public advantage; eſpecially the Cinnamon-tree, which will grow as well in ſome of our iſlands in the Weſt-Indies, as it does in the native places of its growth, and in a few years the trees might be had in plenty; for they propagate eaſily by the berries, as the French experienced in their American iſlands. The Portugueze brought ſome of the Cinnamon-trees from the Eaſt-Indies, and planted them on the iſland of Princes, on the coaſt of Africa, where they now abound, having ſpread over a great part of the iſland; there is alſo one tree now growing at the Madeiras, which I have been informed is a male, ſo never produces berries.

The Camphire-tree does not require any artificial heat in winter, ſo that if they are placed in a warm dry green-houſe they will thrive very well. During the winter ſeaſon they muſt be ſparingly watered, and in the ſummer they ſhould be placed abroad in a warm ſituation, where they may be defended from ſtrong winds, and not too much expoſed to the direct rays of the ſun; but during this ſeaſon, they muſt be frequently refreſhed with water.

They may be propagated by laying down the young branches in autumn, which ſhould be treated in the ſame manner as is before directed for the Benjamin.

The tenth ſort requires a ſtove to preſerve it through the winter in England; this is propagated by ſeeds, which muſt be procured from the country where it grows naturally.

This plant requires the ſame treatment as the Coffee-tree, ſo ſhould be planted in a ſtove, with that and other tender plants of thoſe warm countries, and always remain there.

The eleventh and twelfth ſorts have been generally confounded by moſt, if not all the writers who have treated of them; though their bark, which is the material part of theſe trees in uſe, is pretty eaſily diſtinguiſhed by the dealers in theſe commodities.

Dr. Linnæus is certainly miſtaken in referring the latter to the figure of Dr. Burman, which he has given in his Hiſtory of Ceylon plants, by the title of Cinnamomum perpetuo florens, &c. which is a true repreſentation of the male Cinnamon-tree, and is not the Caſſia Lignea; but as there are plants of all theſe ſorts now in the Britiſh Iſlands of America, ſo we may hope ſoon to have their ſpecies better aſcertained.

The plants of both theſe kinds are not ſo tender as moſt people do imagine, and the treating of thoſe plants which have been brought to England ſo tenderly has deſtroyed them; for ſo far as I have made trial of their culture it has appeared, that great heat is very prejudicial to them; therefore I would adviſe thoſe perſons who may have any of the plants come under their care, to treat them in a different manner, otherwiſe there will be little hopes of keeping them; for when the plants have taken new root in the pots, they ſhould in ſummer be placed in a glaſs-caſe, where they may have plenty of air in warm weather, and in winter placed in a ſtove kept moderately warm.

LAURUS ALEXANDRINA. See Ruscus.

LAURUS TINUS. See Tinus.

LAWN is a great plain in a park, or a ſpacious plain adjoining to a noble ſeat.

As to the dimenſions of it, it ſhould be as large as the ground will permit; but never leſs, if poſſible, than thirty or forty acres; but this is to be underſtood of Lawns in large parks, for in gardens a Lawn of ſix or eight acres is a reaſonable ſize for gardens of a moderate extent, ten or twelve acres for thoſe of the largeſt ſize.

As to the ſituation of a Lawn, it will be beſt to be in the front of the houſe, and to lie open to the neighbouring country, and not pent up too much with trees.

If the houſe front the eaſt, or ſouth-eaſt, it will be moſt convenient, becauſe the rooms will be ſhaded in the afternoon, and ſo the objects to be viewed from the houſe will be much better ſeen, by the ſun's ſhining upon them at that time of the day; for if the beſt room of the houſe front the Lawn, as it always ſhould do, the afternoon being the moſt uſual time for people of faſhion to ſolace themſelves in ſuch rooms, the ſun will not be offenſive to thoſe rooms, nor will the proſpect be interrupted, but rendered more pleaſant; whereas, were it on the weſt ſide of the houſe, the ſun, by ſhining from the object, and directly againſt thoſe rooms, would, by both, hinder the proſpect, for the generality of proſpects are moſt pleaſant when the ſun ſhines upon the objects.

Beſides, there is another inconvenience, if the Lawn be on the weſt ſide of the houſe, it will give the more way to the weſt wind (which is commonly the greateſt) to injure the houſe, by its having a free paſſage to it.

If the Lawn be on the ſouth ſide of the houſe, it may do well enough, for the reaſons before-mentioned, for the ſun's rays being then darted obliquely, will not ſo much interrupt the proſpect, and the ſun ſhining moſt part of the day on that ſide of the houſe, will ſtill add to the beauty of that front, which ought to be the beſt front in the houſe, therefore a Lawn on that ſide will much help the proſpect of the houſe.

But the moſt deſirable aſpect for a Lawn is that of the ſouth-eaſt, which is generally the moſt favourable point in England; for as the ſun riſes upon the front of the houſe facing this point, ſo it will add a chearfulneſs to the rooms in the morning, and by noon the rays will be oblique to this front, and in the afternoon will have entirely left theſe apartments.

It will not be at all convenient to have the Lawn on the north ſide of the houſe, becauſe it will lay the houſe too open to the cold north winds, &c. therefore it will be more eligible to plant wilderneſſes and woods on the weſt and north ſides of the houſe, by way of ſcreen to it, provided theſe do not ſhut out agreeable objects.

As to the figure of the Lawn, ſome contend for an exact ſquare, others an oblong ſquare, ſome an oval, and others a circular figure; but neither of theſe are to be regarded, for it will be much better if contrived ſo as to ſuit the figure of the ground; and as there ſhould be trees planted for ſhade on the boundaries of the Lawn, ſo the ſides may be broken by irregular plantations of trees; for if there are not ſome good proſpects beyond the Lawn, it will be proper to have it bounded on every ſide by plantations, which may be brought round pretty near to each end of the houſe, ſo that perſons may ſoon get into ſhade, which is a very deſirable thing in hot weather; for where that is wanting, few perſons care to ſtir abroad when the ſun ſhines warm.

If in the plantations round the Lawn, the trees are placed irregularly, ſome breaking much forwarder on the Lawn than others, and not crowded too cloſe together, they will make a much better appearance than any regular plantations can poſſibly do; and if there are varieties of trees properly diſpoſed, they will have a good effect; but it ſhould be obſerved, that no other but thoſe which make a fine appearance, and that grow large, ſtrait, and handſome, ſhould be admitted here, as they are placed in the conſtant view from the houſe.

Many perſons have preferred the Lime-tree for this purpoſe, on account of their regular growth; but as the leaves of this tree often change their colour, and begin to fall very ſoon in autumn, occaſioning a great litter in the garden; and from the end of July the trees make but an indifferent appearance, ſo they are not to be eſteemed for theſe plantations.

The Elm, Oak, Beech, and Cheſtnut, among the deciduous trees, are to be preferred to all others, as they keep their leaves late in autumn; and theſe are all of them large growing trees, ſo are very proper for this purpoſe.

If there are ſome clumps of Evergreen trees intermixed with the deciduous trees in this plantation, if they are properly diſpoſed, it will add to the beauty, eſpecially in the winter ſeaſon; the beſt ſorts for this purpoſe are Lord Weymouth's Pine, the Silver and Spruce Firs, which will grow faſt, and become large trees; and as the two latter ſorts always grow pyramidically, ſo they will have a good effect to the ſight, if they are rightly placed, but they ſhould not be intermixed in the ſame clumps with the deciduous trees; but as theſe generally feather out their branches near the ground, they ſhould be planted where they do not obſtruct the view of any diſtant objects.

But as moſt perſons who take pleaſure in beautifying their ſeats in the country, are in haſte for ſhade, they generally plant the trees too cloſe together, and often in ſuch a manner as to render it difficult when the trees are advanced to reduce their number, without injury to the deſign; therefore thoſe trees ſhould be firſt planted, which are deſigned to remain, and then there may be ſome few others planted for preſent ſhade, which may afterward be taken away. When perſons who are beautifying their ſeats meet with full grown trees on the ſpot, it is a great pleaſure, for theſe ſhould not be deſtroyed, if they can poſſibly ſtand without prejudice.

LAWSONIA. Lin. Gen. Plant. 433. Henna. Ludw. 143.

The CHARACTERS are,

The flower has a ſmall permanent empalement, divided into four parts at the top. The flower is compoſed of four oval ſpear-ſhaped petals, which ſpread open, and eight ſlender ſtamina the length of the petals, which ſtand by pairs between them, terminated by roundiſh ſummits. It hath a roundiſh germen, ſupporting a ſlender permanent ſtyle, crowned by a headed ſtigma. The germen afterward becomes a globular capſule ending in a point, having four cells, filled with angular ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's eighth claſs, intitled Octandria Monogynia, which includes thoſe plants whoſe flowers have eight ſtamina and one ſtyle.

The SPECIES are,

1. LAWSONIA (*Inermis*) ramis inermibus. Flor. Zeyl. 134. *Lawſonia whoſe branches have no ſpines.* Liguſtrum Ægyptiacum latifolium. C. B. P. 476. *Broad-leaved Egyptian Privet, called Alhenna, or Henna, by the Arabians.*
2. LAWSONIA (*Spinoſa*) ramis ſpinoſis. Flor. Zeyl. 134. *Lawſonia with prickly branches.* Rhamnus Malabaricus MAIL-ANSKI. Pluk. Alm. 38. tab. 220. *Malabar Buckthorn, called Mail-anſki.*

The firſt ſort grows naturally in India, Egypt, and other warm countries, where it riſes with a ſhrubby ſtalk eight or ten feet high. The branches come out by pairs oppoſite; theſe are ſlender, and covered with a whitiſh yellow bark, and garniſhed with oblong ſmall leaves of a pale green, ending in acute points, placed oppoſite. The flowers are produced in looſe bunches at the end of the branches; they are of a gray or dirty white colour, and are compoſed of four ſmall petals which turn backward at the top. The flowers are ſucceeded by roundiſh capſules with four cells, filled with angular ſeeds.

The leaves of this ſhrub are much uſed by the Egyptian women to colour their nails yellow, which they eſteem an ornament.

The ſecond ſort grows naturally in both Indies, for I have received ſpecimens of it from the Spaniſh Weſt-Indies, where it was found growing naturally in great plenty.

This riſes with a woody trunk eighteen feet high or more. The wood is hard and cloſe, covered with a light gray bark. The branches come out alternate, and are garniſhed with oblong oval leaves, which ſtand without order; and at the joints where the leaves are placed, come out ſingle, ſtrong, ſharp thorns. The flowers are produced in looſe bunches from the ſide of the branches; they are of a pale yellow colour, and of a diſagreeable ſcent; they have four petals, which ſpread open; between each of theſe are ſituated two pretty ſtrong ſtamina, terminated by roundiſh ſummits. After the flowers are paſt, the germen becomes a roundiſh capſule with four cells, including many angular ſeeds.

Theſe plants are both propagated by ſeeds, which ſhould be ſown on a hot-bed early in the ſpring, that the plants when they come up may have time to get ſtrength before winter. When the plants are fit to remove, they ſhould be each planted in a ſmall pot filled with light ſandy earth, and plunged into a hot-bed of tanners bark, where they muſt be ſcreened from the ſun till they have taken new root; then their treatment ſhould be the ſame as that of the Coffee-tree, with this difference only, not to let theſe plants have ſo much water; but eſpecially in the winter, during which ſeaſon it ſhould be given to them very ſparingly, for by over-watering theſe plants I have known many of them deſtroyed; theſe plants are too tender to thrive in the open air in England, ſo they muſt conſtantly remain in the ſtove, but in hot weather they ſhould have plenty of free air admitted to them.

LAYERS. Many trees and ſhrubs may be propagated by Layers, which do not produce ſeeds here, ſo are not eaſily increaſed by any other method.

This is to be performed by ſlitting the branches a little way upward, and laying them under the mould about half a foot; the ground ſhould firſt be well digged and made very light, and after they are laid they ſhould have a little water given them.

If they do not comply well in the laying of them down, they muſt be pegged down with a forked ſtick cut in form of a hook to keep them down; if the Layers have taken ſufficient root by the next winter, they muſt be cut off from the main plants, and planted in the nurſery, as is directed about ſeedlings.

Some twiſt the branch or bare the rind, and if it be out of the reach of the ground, they faſten a tub or baſket near the branch, which they fill with good mould, and lay the branch in it.

Laying of Trees.

This operation is thus performed:

1ſt, Take ſome of the moſt flexible boughs and lay them into the ground about half a foot deep in fine freſh mould, faſtening them down with forked ſticks, leaving them with the end of the Layer about a foot or a foot and a half out of the ground, and keep them moiſt during the ſummer ſeaſon, and they will probably have taken root and be fit to remove in autumn, and if they have not by that time taken root they muſt lie longer.

2dly, Tie a piece of wire hard round the bark of the bough, at the place you intend to lay in the ground, and twiſt the ends of the wire, ſo that they may not untie, and prick the place above the wire through the bark, with an awl in ſeveral places, and then lay it in the ground as before directed; this will often ſucceed when the other fails.

3dly, Cut a ſlit upwards at a joint, as is practiſed in laying of Carnations, which by gardeners is called tonguing the Layers.

4thly, Twiſt the part of the branch deſigned to lay in the ground like a withy, if it is pliable, and lay it into the ground as directed in the firſt way of laying.

5thly, Cut a circle almoſt round about the bough (that is deſigned to be laid) half an inch, at the place that is moſt convenient to lay into the ground, and manage it as is directed in the firſt method of laying.

The ſeaſon for laying hardy trees that ſhed their leaves is in October, but for ſuch as are tender in the beginning of March; for Evergreens, June or July are good ſeaſons.

Though Layers may be laid at any time in the year, yet the before-mentioned ſeaſons are moſt proper, for the reaſons following, becauſe they have the whole winter and ſummer to prepare and draw root; for at theſe times of the year the ſun has ſufficient power on the ſap of the tree to feed the leaf and bud, but has not power ſufficient to make a ſhoot.

And if that ſmall quantity of ſap that does ariſe be hindered, as it will by ſome of the preceding ways of laying, the leaves and buds will gently crave of the Layer, and by that means will prepare the Layer to take root, or put forth roots a little to maintain itſelf, finding it cannot have it from the mother plant.

And therefore, becauſe it wants but little nouriſhment at that time of the year, it is better to lay Layers of trees, or to ſet cuttings than at other times, either in the autumn, when the ſap ſtirs but little, or in the ſpring when it begins to riſe, becauſe it is then apt to come too ſuddenly to draw ſap from the Layer, before the Layer has drawn or prepared for root; but for ſome ſorts the middle of ſummer is beſt.

However, the ſpring or ſummer may do well for ſmall plants, becauſe ſuch plants being but ſhort-lived draw root the quicker.

If you would lay young trees from a high ſtandard, the boughs of which cannot be bent down to the ground, then you muſt make uſe of Oſier baſkets, boxes, or pots, filled with fine mould, mixed with a little rotten Willow duſt, which will keep moiſture to aſſiſt the Layer in taking root; this baſket, box, &c. muſt be ſet upon a poſt or treſſel, &c. and the bough muſt be laid according to either of the four firſt ways of laying, but too much head muſt not be left on, leſt that be injured by the wind, or by its own motion rub off the tender root; and the ſmaller the boughs are, the leſs way they ſhould be left out of the ground, and care muſt be taken to keep them clear from weeds.

The harder the wood of the tree is, the young ſhoots will take root beſt; but if the wood be ſoft, the older boughs will take root the beſt.

There are many kinds of trees and plants which will not put out roots from their woody branches, though laid down with the utmoſt care; yet if the young ſhoots of the ſame year are laid in July, they will often put out roots very freely, ſo that when any plants are found difficult to propagate by Layers in the common way, they ſhould be tried at this ſeaſon; but as theſe ſhoots will be ſoft and herbaceous, they muſt not have too much wet, for that will cauſe them to rot; therefore it will be a better method to cover the ſurface of the ground over the Layers with Moſs, which will prevent the ground from drying too faſt, ſo that a little water now and then will be ſufficient.

LEAVES. A Leaf is defined to be a part of a plant extended into length and breadth, in ſuch a manner as to have one ſide diſtinguiſhable from the other; they are properly the moſt extreme part of a branch, and the ornament of the twigs, and conſiſt of a very glutinous matter, being furniſhed every where with veins and nerves; one of their offices is, to ſubtilize and give more ſpirit to the abundance of nouriſhing ſap, and to convey it to the little buds.

We ſhall firſt conſider the diſtinctions which are made by botaniſts in their definitions of the ſhape and form of Leaves in their titles and deſcriptions of plants, and afterward conſider their uſes in vegetation.

The Leaf of a plant or tree is diſtinguiſhed from that of flowers, the firſt is called Folium in Latin, and the other Petalum; therefore what is to be underſtood here of Leaves, are thoſe which are ranged on the branches and ſtalks of plants, and have no connection with the flower.

Theſe Leaves are either ſimple or compound.

Simple Leaves are thoſe of which the foot-ſtalk or petiole ſupports but one, compound are thoſe of which the foot-ſtalk ſuſtains many Leaves or ſmall foliola.

Simple Leaves differ in reſpect to circumſcription, angles, ſinus, apices, margin, ſuperficies and ſubſtance; circumſcription conſiders the form of the circumference of Leaves where there are no angles or ſinuations; in which reſpect Leaves are,

Orbiculate, or round Leaves (*Orbiculatum*) are ſuch whoſe breadth are equal to their length, and every part of their edges equally diſtant from the center, as in fig. 1.

A roundiſh Leaf (*Subrotundum*) when the Leaf is nearly orbiculate, as in fig. 2.

An oval or egg-ſhaped Leaf (*Ovatum*) when the length of the Leaf exceeds the breadth, and the baſe or lower part of it forms a ſegment of a circle; but the upper extremity is not in proportion, but ſmaller, as in fig. 3.

An obverſe oval Leaf is one whoſe foot-ſtalk is fixed to its ſmaller end.

An oval or elliptic Leaf (*Ovale ſive ellipticum*) is one whoſe length exceeds its breadth, and both ends are narrower than the ſegments of circles, as fig. 4.

A parabolical Leaf (*Parabolicum*) is one whoſe length exceeds its breadth, and is narrowed from the baſe upward, ſo becomes half egg-ſhaped, fig. 5.

A ſpatulated Leaf (*Spatulatum*) is of a roundiſh figure, but narrow at the baſe, and linearly lengthened, fig. 6.

A wedge-ſhaped Leaf (*Cuneiforme*) is one whoſe length exceeds the breadth, and is narrowed to the baſe, fig. 7.

An oblong Leaf (*Oblongum*) is one whoſe length greatly exceeds its breadth, and each extremity is narrower than a ſegment of a circle, fig. 8.

A ſpear-ſhaped or ſpear-pointed Leaf (*Lanceolatum*) is oblong, and grows narrower toward both ends, and terminates in a point, fig. 9.

A linear Leaf (*Lineare*) is one whoſe two ſides run almoſt parallel to each other; they are uſually narrow, and ſomewhat broader in the middle than at the two ends, fig. 10.

A chaffy Leaf (*Aceroſum*) is when the linear Leaf ſtays on the tree, and is evergreen, as in the Fir, Yew, &c. fig 11.

An awl-ſhaped Leaf (*Subulatum*) is one which is linear below, but gradually contracting towards the top, fig. 12.

A triangular Leaf (*Triangulare*) is when the diſk is ſurrounded by three prominent angles, fig. 13.

A quadrangular and quinquangular Leaf, only differ from the former in the number of their ſides or angles, fig. 14.

A deltoide Leaf is one with four angles, of which thoſe of the extremities are farther diſtant from the center than thoſe of the ſides, fig. 15.

A round Leaf (*Rotundum*) is one without any angles.

A ſinus (*or Hollow*) is uſed to expreſs thoſe openings or cavities in Leaves which diſtinguiſh them into parts.

A kidney-ſhaped Leaf (*Reniforme*) is of a roundiſh figure, and hollowed a little at the baſe, but without any angles, fig. 16.

A heart-ſhaped Leaf (*Cordatum*) when they are ovate and hollowed a little at the baſe, but without any angles, fig. 17.

A moon-ſhaped Leaf (*Lunulatum*) is a roundiſh Leaf hollowed at the baſe, with two curvilinear angles in form of ſickles, fig. 18.

An arrow-ſhaped Leaf (*Sagittatum*) is one which is triangular, and hollowed at the baſe for the inſertion of the foot-ſtalk, fig. 19.

A heart arrow-ſhaped Leaf (*Cordatum-ſagittatum*) is like the former, but the ſides of it are convex, fig. 20.

A ſpear-pointed Leaf (*Haſtatum*) is of a triangular form, the ſides and baſe of which are hollowed, and the angles ſpreading ſo as to reſemble a Leaf compoſed of three parts, fig. 21.

A fiddle-ſhaped Leaf (*Panduræ forme*) is oblong, larger at both ends than in the middle, the two ſides being compreſſed like the body of a violin, fig. 22.

A cleft or divided Leaf (*Fiſſum*) is divided by linear ſinuations and ſtrait margins; from the number of the diviſions they are termed a two, three, or many pointed leaf, fig. 23.

A lobated Leaf (*Lobatum*) is one which is divided almoſt to the midrib, into parts which ſtand diſtant from each other, and have convex margins according to the number of theſe parts; it is called bilobed, trilobed, or quadrilobed, &c. fig. 24.

A handed Leaf (*Palmatum*) is one which is divided into ſeveral longitudinal ſegments down to the baſe, where they are united, and reſemble an open hand, fig. 25.

A wing-pointed Leaf (*Pinnatifidum*) is one which is tranſverſly divided into oblong horizontal diviſions, fig. 26.

A lyre-ſhaped Leaf (*Lyratum*) is one which is divided into tranſverſe ſegments, the upper ones being larger than the lower, which are farther aſunder, fig. 27.

A laciniated or jagged Leaf (*Laciniatum*) is one whoſe ſides are variouſly divided into jags, which are again divided without any order, fig. 28.

A ſinuated Leaf (*Sinuatum*) is one which has many ſinuations on its ſides, but is not indented or notched on its edges, fig. 29.

An indented ſinuated Leaf (*Dentato-ſinuatum*) is one like the former, but the ſide lobes are of a linear figure.

A divided Leaf (*Partitum*) is one which is divided into many parts to the baſe, ſo as to appear like many Leaves till cloſely examined. Theſe are called bipartite, tripartite, &c. according to the number of parts, fig. 30.

An entire Leaf (*Integrum*) is one that is undivided, and has ſmooth edges.

Apex tip, is the extremity in which the Leaf terminates; Leaves in reſpect to theſe are termed,

A truncated Leaf (*Truncatum*) is one whoſe ſummit ſeems as though it were cut off by a ſtrait line, in a tranſverſe direction.

A bitten Leaf (*Præmorſum*) is one which is terminated by very blunt unequal cuts, fig. 31.

A blunt Leaf (*Retuſum*) is one whoſe extremity is terminated by an obtuſe ſinus, fig. 32.

A nicked Leaf (*Emarginatum*) is one whoſe extremity is a little notched, fig. 33.

An obtuſe Leaf (*Obtuſum*) is one whoſe point is terminated bluntly, or by a ſegment of a circle, fig. 34.

A ſharp Leaf (*Acutum*) is one whoſe point is terminated in an acute angle, fig. 35.

An acuminated Leaf (*Acuminatum*) is one which is terminated by an awl-ſhaped point, fig. 36.

A pointed obtuſe Leaf (*Obtuſum acumine*) is one whoſe upper part is rounded, but draws to an acute point, fig. 37.

A claſper Leaf (*Cirrhoſum*) is one which terminates with a tendril, fig. 38. as in Glorioſa, Flagellaria, &c.

The margin of a Leaf is the outermoſt boundary of its ſides, excluſive of its diſk or middle, ſo in reſpect to their margin are,

A ſpinous Leaf (*Spinoſum*) is one whoſe edge or border ends with hard ſtiff prickles, fig. 39.

An indented Leaf (*Dentatum*) is one whoſe edge has horizontal points of the ſame conſiſtence with the Leaf, but are ſeparated from each other, fig. 40.

A ſawed Leaf (*Serratum*) is one whoſe edges are ſharply notched like the teeth of a ſaw, which make acute angles bending toward the top, fig. 41.

A backward ſawed Leaf (*Retrorſo-ſerratum*) is one whoſe ſerratures or teeth, are bent toward the baſe of the Leaf.

A double ſawed Leaf (*Duplicato-ſerratum*) is one whoſe edges are ſawed with larger teeth, and the edges of theſe are again ſawed in the ſame manner.

A notched Leaf (*Crenatum*) is one whoſe edges are indented with angles, which neither turn toward the point nor baſe. When theſe indentings terminate obtuſely, it is called obtuſe crenated; when acutely, acute crenated; when the indentures are again indented, it is called double crenated (*Duplicato-crenatum,*) fig. 42.

A bowed or ſerpentine Leaf (*Repandum*) is one whoſe margin has ſeveral obtuſe ſinuſes which are inſcribed with the ſegments of circles, fig. 43.

A cartilaginous or griſly Leaf (*Cartilagineum*) is one whoſe edge is furniſhed with a firm cartilage of a different ſubſtance with the Leaf, fig. 44.

A ciliated Leaf (*Ciliatum*) is one whoſe edge is ſet with parallel hairs, ſo as to reſemble the hairs of the eye-lid, fig. 45.

A torn Leaf (*Laceratum*) is one whoſe edges are cut into ſegments of irregular ſhapes.

A gnawed Leaf (*Eroſum*) is one which is ſinuated, and the ſinuſes have their edges again indented with ſmall obtuſe ſinuations, fig. 46.

A very entire Leaf (*Integerrimum*) is one whoſe margin is entirely free of all notches or indentures.

The ſurface (*Superficies*) is the outſide, or what covers the diſk of the Leaf, and reſpects both the upper and under ſurface, ſo are termed,

A viſcous Leaf (*Viſcidum*) has its ſuperfices covered with a clammy moiſture which is not fluid, but ſticky.

A downy Leaf (*Tomentoſum*) is one whoſe ſurface is covered with a nap of interwoven hairs ſo ſhort and fine, that the eye does not diſtinguiſh them ſingly, though the Leaf is evidently downy both to the ſight and touch, fig. 47.

A woolly Leaf (*Lanatum*) is one whoſe ſurface is covered with a kind of woolly ſubſtance, like a ſpider's web, as in Salvia, Sideritis, &c.

A hairy Leaf (*Piloſum*) has its ſurface furniſhed with long diſtinct hairs, fig. 48.

A rough or ſtinging Leaf (*Hiſpidum*) is one whoſe ſurface is covered with rigid hairs, which either ſting or prick on being touched, fig. 49.

A rough Leaf (*Scabrum*) is one whoſe ſurface has on it ſeveral little irregular prominences.

A prickly Leaf (*Aculeatum*) is one whoſe ſurface is covered with ſtrong ſharp points or thorns, which adhere lightly to the ſurface.

A ſtreaked or channelled Leaf (*Striatum*) is when its ſurface has a number of parallel longitudinal furrows.

A pimpled Leaf (*Papilloſum*) is one whoſe ſurface has many little roundiſh protuberances like nipples or bladders, fig. 50.

A punctuated Leaf (*Punctatum*) is one whoſe ſurface has many hollow points diſperſed over it.

A bright or ſplendent Leaf (*Nitidum*) is one whoſe ſurface is ſmooth and ſhining, as if poliſhed by art.

A plaited Leaf (*Plicatum*) is one which has ſeveral angular riſings and hollows towards its borders, as if folded up, as in Alchimilla, fig. 51.

A waved Leaf (*Undulatum*) is one whoſe ſurface toward the edges riſes and falls convexly like the waves of the ſea.

A curled Leaf (*Criſpum*) is when the circumference of the Leaf grows larger than the diſk will admit, ſo that the whole ſurface is raiſed in waves, fig. 52.

A rough leaf (*Rugoſum*) is one whoſe veins are contracted and ſunk below the diſk, and the intermediate fleſhy parts riſe in irregular forms, ſo as to appear rough, fig. 53.

A hollow or concave Leaf (*Concavum*) is one whoſe margin contracts, ſo is leſs than the middle, and is ſunk down or hollowed.

A veined Leaf (*Venoſum*) is one whoſe veins are branched, and appear to the naked eye.

A convex Leaf (*Convexum*) is one whoſe middle riſes into a protuberant form.

A nervous Leaf (*Nervoſum*) is when the veins are extended lengthways from the baſe toward the ſummit without branching, fig. 54.

A coloured Leaf (*Coloratum*) is one which has other colours than green.

A ſmooth Leaf (*Glabrum*) is one whoſe ſurface is ſmooth, without any inequalities.

The ſubſtance of a Leaf reſpects the conditions of its ſides, in this reſpect Leaves are,

A taper Leaf (*Teres*) is one of a thick ſubſtance, and for the moſt part of a cylindrical form.

A half taper Leaf (*Semicylindraceum*) is one which is of a cylindrical form, flatted on one ſide.

A hollow Leaf (*Tubuloſum*) is one which is hollow like a pipe, as thoſe of the Onion.

A fleſhy Leaf (*Carnoſum*) is one that is ſucculent or full of pulp.

A compreſſed Leaf (*Compreſſum*) is one whoſe marginal ſides are preſſed, ſo that the ſubſtance of the Leaf is larger than the diſk.

A plane Leaf (*Planum*) is one whoſe ſurfaces are every where parallel.

A gibbous Leaf (*Gibbum*) is one which is convex on both ſides, the middle being fuller of pulp.

A depreſſed Leaf (*Depreſſum*) is one whoſe diſk is more depreſſed than the ſides.

A guttered Leaf (*Canaliculatum*) is one which has a longitudinal deep furrow running through the middle of the Leaf, and is almoſt cylindrical, fig. 55.

A double-faced Leaf (*Ancipites*) is one whoſe diſk is convex, and has two prominent longitudinal angles.

A ſword-ſhaped Leaf (*Enſiforme*) is one with thin edges, with a prominent rib running from the baſe to the point in the middle.

A faulchion or ſcymiter-ſhaped Leaf (*Acinaciforme*) is one which is fleſhy and compreſſed, with one of its edges convex and narrow, the other thick and ſtrait, fig. 56.

An ax-ſhaped Leaf (*Dolabriforme*) is one which is roundiſh, obtuſe, and compreſſed, gibbous on the outſide, the inſide ſharp-edged and taper below, fig. 57.

A tongue-ſhaped Leaf (*Linguiforme*) is linear, fleſhy, and obtuſe, convex on the under ſide, and has often cartilaginous edges, fig. 58.

A two-edged Leaf (*Anceps*) is one which has two prominent angles, running lengthways on a convex diſk.

A three-cornered Leaf (*Triquetrum*) has three longitudinal plain ſides like an awl-ſhaped Leaf.

A three-edged Leaf (*Trigonal*) is much like the former, but in this the ribs are ſharp and membranaceous, the ſurface of the Leaf being channelled. When a Leaf has four or five angles, it is called tetragonal and pentagonal, &c.

A furrowed Leaf (*Sulcatum*) is one that has ſeveral ridges running lengthways, which have obtuſe ſinuſus, fig. 59.

A keel-ſhaped Leaf (*Carinatum*) is one that has the under part of the diſk prominent the whole length, and the upper concave like the keel of a boat.

A membranaceous Leaf (*Membranaceum*) is one wholly compoſed of membranes, without any apparent pulp between.

A compound Leaf (*Compoſitum*) in general means one, which is formed of ſeveral ſmall Leaves ſtanding upon one foot-ſtalk, but theſe Leaves are diviſible again to the ſtructure and poſition of the ſmall Leaves.

1ſt, Into ſuch as are properly and diſtinctly called compound Leaves; 2dly, the decompound; 3dly, the ſupradecompound, of each of theſe in its place.

In deſcribing theſe kinds of Leaves, the whole Leaf which is the reſult of the combination, is conſidered as one Leaf, called (*Folium*) and the ſmall leaves which together compoſe it (*Folioli*) or lobes.

A ſimple compound Leaf, is one whoſe ſimple foot-ſtalk bears more than one Leaf.

A jointed one (*Articulatum*) is when one Leaf grows out of the point of another, fig. 60.

A fingered Leaf (*Digitatum*) is one which is compoſed of ſeveral ſmall Leaves joining to one foot-ſtalk at their baſe, ſpreading open like the fingers of a hand, fig. 61.

A two-lobed Leaf (*Binatum*) is one with two ſmall Leaves on one foot-ſtalk, fig. 62.

A three-lobed Leaf (*Ternatum*) is one with three ſmall leaves, which is frequently called a trifoliate Leaf, fig. 63.

A cinquefoil Leaf (*Quinatum*) has five ſmall Leaves on the ſame foot-ſtalk.

A winged Leaf (*Pinnatum*) is one which has many ſmall Leaves, ranged on each ſide a ſingle foot-ſtalk like wings; of theſe there are ſeveral kinds.

An unequal winged Leaf (*Pinnatum cum impare*) is a winged Leaf, terminated by an odd lobe or (*Folioli*) fig. 64.

A claſper-winged Leaf (*Pinnatum cum cirrho*) is a winged Leaf ending with a tendril or claſper, fig. 65.

An abrupt-winged Leaf (*Abruptum*) is a winged Leaf not terminated by an odd lobe or claſper, fig. 66.

An oppoſite-winged Leaf (*Oppoſite pinnatum*) is when the ſmall Leaves or lobes are placed oppoſite on the midrib.

An alternate-winged Leaf (*Alternatim pinnatum*) is when the ſmall Leaves ſtand alternate.

An interrupted-winged Leaf (*Interruptè pinnatum*) is when there are ſmaller lobes intermixed with larger upon the ſame midrib, fig. 67.

A jointed-winged Leaf (*Articulatè pinnatum*) is when the common foot-ſtalk is jointed, fig. 68.

A running-winged Leaf (*Decurſivè pinnatum*) is one whoſe ſmall Leaves run along the foot-ſtalk from one to another, fig. 69.

A conjugated Leaf (*Conjugatum*) is one which has but two ſmall Leaves on the ſame foot-ſtalk.

We next proceed to the decompounded Leaves.

A decompounded Leaf (*Decompoſitum*) is one whoſe foot-ſtalk is once divided, and joins together many ſmall Leaves.

A double conjugated Leaf (*Bigeminatum*) is one whoſe foot-ſtalk divides in forks, and connects four ſmall Leaves on the top, or it is compoſed of two conjugations.

A double trifoliate Leaf (*Biternatum*) is one whoſe foot-ſtalk is divided, and each diviſion ſuſtains three ſmall Leaves, fig. 70.

A double-winged Leaf (*Bipinnatum*) is one whoſe foot-ſtalk is divided, and theſe diviſions have ſmall Leaves ranged on their ſide like wings, fig. 71.

A foot-ſhaped or branched Leaf (*Pedatum*) is one whoſe foot-ſtalk is divided, and has ſome ſmall Leaves placed on the inner ſide, as in Paſſiflora and Arum, fig. 72.

A greater compounded Leaf (*Supra decompoſitum*) is one whoſe foot-ſtalk is many times divided, and each diviſion is garniſhed with ſmall Leaves.

A triternate Leaf (*Triternatum*) is one whoſe foot-ſtalk connects three double trifoliate Leaves.

A triple-winged Leaf (*Tripinnatum*) is one compoſed of ſeveral double-winged Leaves; if theſe are terminated by two ſmall Leaves, they are ſaid to be abrupt, fig. 73. but when they are terminated by an odd one, they are called an irregular, triple, winged Leaf, fig. 74.

We next come to conſider the diſtinctions of Leaves from their place, poſition, inſertion, or their direction, when joined to the other parts of plants.

A ſeed Leaf (*Seminale*) is the firſt Leaf of the plant, and is what former writers called cotyledones; theſe are different in form and ſubſtance from the other Leaves, fig. 75.

A bottom Leaf (*Radicale*) is one whoſe foot-ſtalk riſes immediately from the root.

An upper or ſtalk Leaf (*Caulinum*) is one which grows from the ſtalk of the plant, fig. 76.

An axillary Leaf (*Axillare*) is one which grows from the inſertions of the branches, fig. 77.

A flower Leaf (*Florale*) is one that is inſerted near the flower, and never appears but with it, fig. 78.

A ſtarry Leaf (*Stellate*) fig. 79. or whorled Leaf (*Verticillata*) is when ſeveral Leaves are diſpoſed in whorls round the ſtalk, fig. 80.

Oppoſite Leaves (*Oppoſita*) are when thoſe upon the ſtalks ſtand by pairs on each ſide, fig. 81.

Alternate Leaves (*Alterna*) are when they ſtand alternate above each other, fig. 82.

Sparſed Leaves (*Sparſa*) are ſuch as ſtand without order over the whole plant.

Cluſter Leaves (*Conferta*) are ſuch as come out from the ſide of the branches in cluſters, and are ſo cloſe to one another, that it is not eaſy to diſcover their exact ſituation, fig. 83.

Imbricated Leaves (*Imbricata*) are ſuch as are placed over each other like tiles on a houſe, or the ſcales of fiſhes, fig. 84.

Faſciculated Leaves (*Faſciculata*) are ſuch as grow in cluſters from the ſame point, fig. 85.

Diſticha is when the Leaves are ranged along only upon two ſides of the branches, as in the Fir-tree.

A target or ſhield-ſhaped Leaf (*Peltatum*) is one whoſe foot-ſtalk is fixed to the diſk, and not to the baſe or edge of the Leaf, fig. 86.

Petiolatum is when the foot-ſtalk is inſerted to the baſe of the margin, fig. 87.

Seſſile is when the Leaf ſits cloſe to the ſtalk or branch, and has no foot-ſtalk, fig. 88.

A running Leaf (*Decurrens*) is when the Leaf adheres to the ſtalk or branch, and is extended along the ſtalk from the baſe, ſo as to form a leafy border on each ſide the ſtalk, fig. 89.

Amplexicaule is when the baſe of the Leaf environs or embraces the ſides of the ſtalk entirely, fig. 90.

Semiamplexicaule, is when the baſe of the Leaf reach but half round the ſtalk.

A perfoliate Leaf (*Perfoliatum*) is one which is perforated by the ſtalk or branch, which do not touch the margin, fig. 91.

Connatum, is when the two oppoſite Leaves cohere at their baſe, ſo as to form one body embracing the ſtalk, fig. 92.

Vaginans, is when the baſe of the Leaf forms a kind of cylinder, embracing the ſtalk like a ſheath, as in Corn, Graſs, fig. 93.

The direction of Leaves.

An adverſe Leaf (*Adverſum*) is one whoſe ſides reſpect the meridian and not the heavens, as the Ginger, &c.

To front LEA.

I. Miller Sculp.

G.R. III
BRITISH MUSEUM

An oblique Leaf (*Obliquum*) is when the baſe of the Leaf regards the ſky, and the ſummit the horizon.

An inflexed or incurved Leaf (*Inflexum*) is one which grows in form of a bow, turning its point toward the ſtalk again, fig. 94.

Adpreſſum, is when the diſk of the Leaf approaches near the ſtalk.

An erect Leaf (*Erectum*) is one ſo ſituated as to make a very acute angle with the ſtalk, fig. 95.

Patens, is when the Leaf does not make ſo acute an angle with the ſtalk as the former, and yet does not ſtand horizontal, fig. 96.

An horizontal Leaf (*Horizontale*) is one which ſtands perfectly at right angles with the ſtalk, fig. 97.

A reclined Leaf (*Reclinatum*) is one whoſe ſummit is lower than the baſe, fig. 98.

A rolled Leaf (*Revolutum*) is one whoſe upper part is rolled downward, fig. 99.

A dependent Leaf (*Dependens*) is one whoſe ſummits point to the earth.

A rooting Leaf (*Radicans*) is one which puts out roots.

A floating Leaf (*Natans*) is one which floats on the ſurface of the water, as the Water Lily, &c.

Demerſum, is uſed to expreſs a Leaf ſunk below the ſurface of the water.

Having explained the ſeveral forms of Leaves, by which botaniſts diſtinguiſh them, and alſo their poſition, both in regard to the other parts of the tree, or plant, and that of the earth, we ſhall next proceed to their ſtructure and uſes; for theſe were not deſigned by the wiſe Creator only for ornament, but they are of more important uſe in vegetation, and are as variouſly conſtructed in their ſeveral parts, as their ſeveral uſes for which they are deſigned.

Some plants have very thick fleſhy Leaves, whoſe pulpy ſubſtance is always moiſt; theſe are ſuch plants as naturally grow upon dry barren rocky places, and for the moſt part are natives of warm countries; and as they perſpire very little in compariſon of moſt other plants, they are adapted to grow in ſuch places where they can receive very little nouriſhment from the earth. Moſt of the Leaves of theſe plants have a thin compact ſkin over their ſurface, with very ſmall minute pores, whereby the deſcending moiſture is thrown off, which, if admitted into the ſubſtance of the Leaves, or ſtalks, would in a very ſhort time cauſe a mortification, and deſtroy the plant.

The Leaves of all thoſe trees and ſhrubs which continue their verdure all the year, have alſo a thin compact ſkin or cover over their ſurfaces, as is eaſily diſcovered by macerating them in water, in order to ſeparate the parenchyma from the veſſels of the leaves, which cannot be effected in any of theſe Evergreens, till the thin parchment-like cover is taken off; theſe trees and ſhrubs are found, by experiment, to imbibe and perſpire but little in the ſame ſpace of time, when compared with the deciduous trees and ſhrubs; and it is principally owing to this cloſe covering, as alſo to the ſmall proportion of moiſture contained in their veſſels, that they retain their verdure, and continue through the winter on the trees. The nutritive juices of theſe plants always abound more or leſs with an oily or terebinthinous quality, which ſecures them from the injury of froſt, ſo that many of theſe evergreen trees are adapted to grow in the coldeſt parts of the habitable world.

In all the Leaves of trees and plants which I have examined, there are two orders of veins or nerves, one belonging to each ſurface; and I have generally obſerved, that the lower lamina or under ſide of the Leaf, had the ramifications larger, and were capable of admitting a liquid to paſs through them, which thoſe of the upper ſurface would not; theſe two orders of veins are inoſculated at ſeveral places, but not ſo cloſely connected, but that they may be eaſily ſeparated, after they have been macerated in water a proper time, for ſome Leaves require a much longer time than others, to render the parenchyma ſoft enough to ſeparate eaſily from the veins without tearing them.

Theſe two laminæ, or orders of veins, are ſuppoſed to be deſtined for different purpoſes; the upper lamina is thought to be air-veſſels, or trachæ, through which the perſpiring matter is protruded, and by which the air is inſpired; that theſe are pores through which that ſubſtance paſſes, which is thrown out of the plants, is pretty evident; for the clammy ſubſtance which is commonly called honey-dew, is always found ſticking to the upper ſurface of Leaves, from whence many have ſuppoſed that this ſubſtance fell from above, and lodged upon the Leaves in the night. This is the Manna which is collected from Aſh-trees in Calabria, and from the Alhagi in Perſia, &c. and is no other than the nutritive juices, or a ſubſtance ſeparated from that, which iſſues from the pores of the Leaves, and is concreted on the ſurface of the Leaves by the cold air; but whenever this is found in quantity upon the Leaves, it is a ſure ſign of a diſeaſed plant.

The lower lamina of veins are ſuppoſed to be deſtined for another purpoſe, which is that of receiving, preparing, and conveying the moiſture imbibed from the riſing vapours of the earth, by which trees and plants are greatly nouriſhed; and for this uſe we ſee how differently the two ſurfaces are formed; the upper one is commonly ſmooth and lucid, and the under is frequently covered with hairs, or a ſoft down, the better to ſtop and detain the riſing vapours, and tranſmit them to the inner veſſels; and where the ſtructure of the Leaves are different, it is found by experience, that their functions alter; for thoſe Leaves, whoſe upper ſurfaces are garniſhed with down or hairs, are found to be the receivers and conveyers of the moiſture, and not the under ones, as in the other plants.

If the ſurfaces of theſe Leaves are altered, by reverſing the branches on which they grow, the plants are ſtopped in their growth, until the foot-ſtalks are turned, and the Leaves recover their former poſition. This ſhews how neceſſary it is to ſupport all thoſe weak ſhoots of plants, which are naturally diſpoſed for upright growth, and that either twine about the neighbouring trees for ſupport, or that put out claſpers, by which they take hold of whatever trees or plants grow near them, and are thereby ſupported; and, on the contrary, how abſurd is that practice of tying up the ſhoots of thoſe plants which are naturally diſpoſed to trail upon the ground; for, in both theſe caſes, nature is reverſed, and conſequently the growth of both ſorts of plants is greatly retarded.

This is one of the great functions for which the Leaves of trees and plants are deſigned; but, beſides this, there are others of equal importance to the well-being of plants and fruits; the firſt is that of the foot-ſtalks of Leaves nouriſhing and preparing the buds of the future ſhoots, which are always formed at the baſe of theſe foot-ſtalks, and during the continuance of the Leaves in perfect health, theſe buds increaſe in their magnitude, and, in the deciduous trees, are brought to maturity before the foot-ſtalks ſeparate from the buds in autumn; but if by accident the Leaves are blighted, or if the entire ſurface of the Leaves are cut off, and the foot-ſtalks are left remaining, yet the buds will decay, or not arrive to their proper ſize, for want of that nouriſhment which is conveyed to them from the Leaves; ſo that whenever trees are diveſted of their Leaves, or thoſe Leaves are cut, or otherwiſe impaired, though it may in either caſe happen when the buds may be nearly formed; yet if it is before the foot-ſtalks ſeparate naturally from the branches, the future ſhoots will be weakened in proportion to the time when this is done; therefore, as from all the experiments which have been made in order to know how ſerviceable the Leaves of trees and plants are to their well-being, it has been found, that where the plants have been diveſted of their Leaves, or their Leaves have been eaten, or cut, during their growth, the plants have been remarkably weakened thereby. This ſhould teach us not to pull, or cut off the Leaves of trees, or plants, on any account, while they retain their verdure or are in health. As alſo how abſurd that common practice is, of feeding down Wheat in the winter and ſpring with ſheep; for by ſo doing, the ſtalks are rendered very weak, and the ears are in proportion ſhorter; nor are the grains of Corn ſo plump and well nouriſhed, as that which is not fed down upon the ſame ground: this is a fact which I can aſſert from many years experience; for when Corn or Graſs is fed down cloſe to the root, the ſucceeding blades will be much finer than if the firſt Leaves had been left remaining; which is evident from all ſheep paſtures, where the Graſs is much finer and ſhorter than in other places; as alſo upon lawns and bowling-greens, where the Graſs is often mowed, the blades will be rendered finer in proportion to the frequency of mowing it, yet the ſpecies of Graſs is the ſame with that on the richeſt paſtures; ſo that although this may be a deſirable thing for lawns, &c. in gardens, yet where regard is had to the produce, this ſhould be avoided.

Beſides theſe, there are other uſes for which Leaves are deſigned, one of which is that of ſhading the buds for the future ſhoots from the ſun, which would exhale and dry up all their moiſture, as alſo the ſhading of the young fruit, which is abſolutely neceſſary during the time of their growth; for I have ſuſpended the Leaves of trees which were growing againſt walls, ſo as to expoſe the fruit to the ſun, and not taken any of them off the branches, yet I have always found thoſe fruits ſo expoſed, have been greatly ſtinted in their growth, and have never arrived to near the ſize of others above and below them on the ſame branches, nor were they ſo well taſted, or replete with juice.

In making this experiment, I was as careful as poſſible not to reverſe the ſurfaces of the Leaves, having been thoroughly convinced, from many repeated experiments, how prejudicial that is to all plants; but notwithſtanding this precaution, the event was as before-mentioned.

Another principal uſe of the Leaves is to throw off by tranſpiration, what is unneceſſary for the growth of the plants, anſwering to the diſcharge made by ſweat in animal bodies; and as plants receive and tranſpire much more, in equal time than large animals, ſo it appears how neceſſary the Leaves are to preſerve the plants in perfect health; for it has been found by the moſt exact calculations, made from repeated experiments, that a plant of the Sun-flower receives and perſpires, in twenty-four hours, ſeventeen times more than a man.

As naturaliſts have generally aſcribed a four-fold uſe to Leaves, I ſhall beg leave to mention them here, and then ſhall give an account of the moſt accurate experiments which have been made to aſcertain the truth of their hypotheſes.

1. Chiefly, that they do in the ſpring time receive the crude humours into themſelves, divide them very minutely, and move them ſtrongly in the utricles, and perhaps draw in from the air what is neceſſary, though unknown to us, and carry back great plenty of elaborate juice to the plant.

2. That there may be a tranſpiration of what is unprofitable, anſwering to the diſcharge made by ſweat; for ſometimes thoſe excretory veſſels of the Leaves are ſo overcharged by the great plenty of diſtending humour [juice,] that they burſt in the middle, and let go the more ſubtile parts; nor is it ſeldom, that, in a hot ſeaſon, great plenty of juices are this way diſcharged and imbibed. Thus Manna is found to exſude [ſweat forth] from the Leaves of certain trees, if a cold night ſhould follow a hot day; and the ſame thing frequently happens in divers other plants and trees, as we learn from the bees flying to the Lime-tree, that they may gather that gumous ſubſtance from their Leaves; and it is from the ſurfaces of the Leaves, as well as from the flowers, thoſe animals collect their honey; but if the heat ſhould be leſs, all the ſuperfluous humours, except thoſe which, perhaps, are tranſmitted by inſenſible tranſpiration thro' the arterial veſſels, exhaling naturally, are ſeen to return into the trunk.

3. That the bibulous veſſels, dried by the diurnal heat, and for this reaſon to be compared to veins, may imbibe, in the night-time eſpecially, thoſe watery parts, which, among others, lie hid in the air under the form of a very thin dew, and ſo make amends for the loſs made by the arteries, by the new moiſture received.

4. Laſtly, the Leaf ſerves chiefly for this purpoſe, that it may keep and nouriſh the eye, or gem, until the gem, by degrees growing out to a greater bulk, preſſes together the veſſels of the foot-ſtalk, from whence the humour is by little and little ſtopped in the Leaf, till it cannot any more return to the foot-ſtalk; which, by the ceaſing of the afflux and reflux of the nutritive juice, grows putrid, whence a conſumption being cauſed, the Leaf dies, and falls off, which is the chief cauſe of the falling of the Leaves in autumn.

The Rev. Dr. Hales, in his excellent Treatiſe of Vegetable Statics, ſpeaking of the perſpiration of plants, gives an account of the following experiments, viz.

That in July or Auguſt he cut off ſeveral branches of Apple-trees, Cherry-trees, Pear-trees, and Apricot-trees, two of a ſort; they were of ſeveral ſizes, from three to ſix feet long, with proportional lateral branches, and the tranſverſe cut of the largeſt part of the ſtems was about an inch diameter.

That he ſtripped off the Leaves of one bough of each ſort, and then ſet their ſtems in ſeveral glaſſes, pouring in known quantities of water.

The boughs with Leaves on them imbibed ſome fifteen ounces, ſome twenty, twenty-five, or thirty, in twelve hours day, more or leſs, in proportion to the quantity of Leaves they had, and when he weighed them at night, they were lighter than in the morning. While thoſe without Leaves imbibed but one ounce, and were heavier in the evening than in the morning, they having perſpired little.

The quantity imbibed by thoſe with Leaves decreaſed very much every day, the ſap-veſſels being probably ſhrunk at the tranſverſe cut, and too much ſaturate with water, to let any more paſs, ſo that uſually in four or five days the Leaves faded and withered much.

He adds, that he repeated the ſame experiments with Elm branches, Oak, Oſier, Willow, Sallow, Aſpen, Currant, Gooſeberry, and Filbert branches, but none of theſe imbibed ſo much as the foregoing, and ſeveral ſorts of Evergreens very much leſs.

He adds alſo another experiment: That on the 15th of Auguſt, he cut off a large Pippin with two inches ſtem, and its twelve adjoining Leaves: that he ſet the ſtem in a little phial of water, which imbibed and perſpired in three days one third of an ounce.

And that at the ſame time he cut off from the ſame tree another bearing twig of the ſame length, with twelve Leaves, no Apple on it, which imbibed in the ſame three days near three-fourths of an ounce.

That about the ſame time, he ſet in a phial of water a ſhort ſtem of the ſame tree, with two large Apples on it, without leaves, and they imbibed near three-fourths of an ounce in two days.

So in this experiment, the Apples and Leaves imbibed four-fifths of an ounce, the Leaves alone near three-fifths, but the two large Apples imbibed and perſpired but one third part ſo much as the twelve Leaves, then the one Apple imbibed the one-ſixth part of what was imbibed by the twelve Leaves; therefore two Leaves imbibe and perſpire as much as one Apple; whence their perſpirations ſeem to be proportionable to their ſurfaces, the ſurface of the Apple being nearly equal to the ſum of the upper and under ſurfaces of the two Leaves.

Whence it is probable that the uſe of theſe Leaves (which are placed juſt where the fruit joins to the tree) is to bring nouriſhment to the fruit.

And accordingly he obſerves, that the Leaves next adjoining to the bloſſoms are in the ſpring very much expanded, when the other Leaves on barren ſhoots are but beginning to ſhoot, and that all Peach Leaves are very large before the bloſſom goes off.

And that, in Apples and Pears, the Leaves are one-third or half grown, before the bloſſom opens, ſo provident is nature in making timely proviſion for the nouriſhing the yet embryo fruit.

He alſo adds another experiment: he ſtripped the Leaves of an Apple-tree branch, and then fixed the great end of the ſtem in the gage, it raiſed the mercury $2 + \frac{1}{2}$ inches, but it ſoon ſubſided, for want of the plentiful perſpiration of the Leaves, ſo that the air came in almoſt as faſt as the branch imbibed water.

And as a farther proof of the influence of the Leaves in raiſing the ſap, he alſo made the following experiment.

On the ſixth of Auguſt, he cut off a large Ruſſet Pippin, with a ſtalk $1 + \frac{1}{2}$ inch long, and twelve adjoining Leaves growing to it.

He cemented the ſtalk faſt in the upper end of a tube, which tube was ſix inches long, and one-fourth diameter; as the ſtalk imbibed the water, it raiſed the mercury four inches high.

That he fixed another Apple of the ſame ſize in the ſame manner, but firſt pulled off the Leaves, and it raiſed the mercury but one inch; that in the ſame manner he fixed a like-bearing twig, with twelve Leaves on it, but no Apple, and it raiſed the mercury three inches.

He then took a like-bearing twig, without either Leaves or Apple, and it raiſed the mercury one-fourth of an inch.

So a twig, with an Apple and Leaves, raiſed the mercury four inches; one with Leaves, only three inches; one with an Apple without Leaves, only one inch.

A Quince, which had two Leaves juſt at the twig's inſertion, raiſed the mercury $2 + \frac{1}{2}$ inches, and held it up a conſiderable time.

A ſprig of Mint, fixed in the ſame manner, raiſed the mercury $3 + \frac{1}{2}$ inches, = to 4 feet 5 inches height of water.

Theſe, and many more experiments of the Rev. Dr. Hales, that curious enquirer into the cauſes, ſtate, and progreſs of vegetation, evidently ſhew the great perſpiration of the Leaves of plants, and their great uſe in raiſing the ſap, and other functions of vegetable nature; to whoſe excellent treatiſe before-mentioned, I refer the curious enquirer.

I ſhall add, That nature has directed us as to the true diſtance we ought to train the branches of trees againſt walls or eſpaliers, which ſhould always be in proportion to the ſize of their Leaves; for if we regard her progreſs in the great varieties of trees, which are within our obſervation, we ſhall always find their branches grow diſtant from each other in proportion to the breadth of their Leaves; and it was upon this account that the Romans ſo much admired the Platanus, becauſe the Leaves, being large, afforded them a kindly ſhade in ſummer, but in winter, when they are deſtitute of Leaves, their branches growing at a great diſtance, eaſily admitted the beams of the ſun.

I ſhall next beg leave to mention a few, out of the many experiments which have been made by Monſ. Bonnet, of Geneva, to prove that moſt Leaves imbibe the moiſture of the air on their under ſurface, and not from their upper: they are as follow:

He gathered the Leaves of ſixteen ſorts of herbaceous plants when fully grown; of each he put ſeveral Leaves upon the ſurface of water in glaſs vaſes, ſome were poſited with their upper ſurface, and others with their under ſurface upon the water; theſe were adjuſted exactly to the ſurface of the water, with great care not to let any moiſture reach their oppoſite ſurfaces, and the ſame care was taken to prevent their foot-ſtalks from receiving any moiſture. The glaſſes in which theſe Leaves were thus placed, were kept in a cloſet, where the air was very temperate; and as the water in the glaſſes evaporated, there was from time to time a ſupply of freſh, which was added with a ſyringe, ſo that the Leaves were not diſturbed. The Leaves were taken from the following plants; the Plantain, the Mullein, the Wake Robin, the great Mallow, the Nettle, the Marvel of Peru, the Kidney-bean, the Sun-flower, the Cabbage, the Balm, the Cock's-comb, the purple-leaved Amaranth, Spinach, and the ſmaller Mallow.

Six of theſe ſorts he found continued green a long time, and theſe were with different ſurfaces upon the water; they were of the following ſorts, the Wake Robin, the Kidney-bean, the Sun-flower, the Cabbage, the Spinach, and ſmall Mallow; among the others the following ſorts were found to draw the moiſture better with their upper ſurface than their under, the Plantain, the Mullein, the great Mallow, the Nettle, the Cock's-comb, and the purple Amaranth.

The Leaves of the Nettle whoſe under ſurface was upon the water, were decayed in three weeks, whereas thoſe whoſe upper ſurface was next the water continued two months.

The Leaves of Mullein, whoſe under ſurface was next the water, did not continue freſh more than five or ſix days, but thoſe whoſe upper ſurface was next the water laſted five weeks.

The Leaves of the purple Amaranth, whoſe upper ſurface was next the water, continued freſh three months, whereas thoſe whoſe under ſurface was next the water, were decayed in a week.

The Leaves of the Marvel of Peru and the Balm, appeared to have the advantage, whoſe under ſurfaces were next the water.

The Leaves of Wake Robin and of the Cock's-comb, whoſe foot-ſtalks only were put into the water, continued freſh a longer time than thoſe which were placed with either ſurface next the water.

The Leaves of the Great Mallow, the Nettle, the Sun-flower, the Marvel of Peru, and Spinach, whoſe foot-ſtalks were plunged into the water, continued freſh a ſhorter time than thoſe which had either of their ſurfaces next the water.

The Leaves of the Mullein, of Plantain, and Amaranth, which received the water at their foot-ſtalk, continued freſh much longer than thoſe, whoſe under ſurface was next the water.

It is not difficult to explain the reaſon of this fact, for the orifices of the ſap-veſſels in the foot-ſtalk, are much larger than thoſe of either ſurface, ſo that the moiſture inſinuates in greater quantities, and with more eaſe, the firſt than by the ſecond way.

After this the ſame gentleman made experiments on the Leaves of ſixteen ſorts of trees and ſhrubs of the following ſorts, the Lilac, the Pear-tree, the Vine, the Aſpen, the Laurel, the Cherry-tree, the Plumb-tree, the Horſe Cheſnut, the White Mulberry, the Lime-tree, the Poplar, the Apricot, the Walnut, the Filbert, the Oak, and the Creeper.

Among theſe ſpecies, he found that the Lilac and the Aſpen imbibed the moiſture on their upper ſurface, equally with the under ſurface; but in all the other ſorts, the under ſurface imbibed it in much greater quantities than the oppoſite. The difference was very remarkable in the Leaves of the White Mulberry, for thoſe whoſe upper ſurface was laid upon the water, faded in five days, whereas the other whoſe under ſurface was next the water, preſerved their verdure near ſix months.

The Vine, the Poplar, and Walnut-tree are very remarkable inſtances, how little diſpoſed the upper ſurfaces of the Leaves of ligneous plants are to imbibe the moiſture; for thoſe of theſe three ſorts, whoſe upper ſurfaces were applied to the water, decayed almoſt as ſoon as thoſe which had no nouriſhment.

In all the experiments made by this curious gentleman upon the various Leaves of trees and herbs, it is remarkable, that all thoſe Leaves which imbibed the moiſture by their upper ſurface, were ſuch as had that ſurface covered with either hairs or down; and on the contrary, where the under ſurface was garniſhed with either hairs or down, the moiſture was imbibed by that ſurface. He likewiſe mentions many experiments made by himſelf, and alſo by Monſ. du Hamel de Monceau, of the Royal Academy of Sciences at Paris, in rubbing the Leaves over with varniſh, oil, wax, and honey, to ſee the effect of theſe upon various Leaves, ſome of which were rubbed over on both ſurfaces, others only upon one; ſome only a part of the ſurface, others the edges of the Leaves were rubbed over, and in ſome only the foot-ſtalks of the Leaves were rubbed with theſe. They likewiſe anointed the trunks of ſome trees and ſhrubs, and left the Leaves and branches in their natural ſtate.

The reſult of theſe experiments was, that where the Leaves were anointed on both ſurfaces with varniſh, they decayed preſently; and where they were anointed with the other things, in proportion as thoſe were moſt penetrating, ſo the Leaves continued a ſhorter time than the others; and where one ſurface only was anointed, they continued much longer than thoſe which were anointed on both; and where the pedicle only was anointed, they continued ſtill longer; but the anointing of the trunks, made no ſenſible alteration, excepting in very hot weather; when they both imagine, that the anointing them was of ſervice, by hindering the too great tranſpiration which might weaken the trees; for they obſerved, that thoſe trees which were varniſhed, ſuffered leſs from the violent heat, than the trees which were left in their natural ſtate.

Monſ. Bonnet alſo obſerved, that thoſe Leaves which were varniſhed, the tender parts of the Leaves were deſtroyed by it, and the tough fibres only were left remaining.

As it would ſwell this work much beyond its intended bulk, were I to mention more of theſe curious experiments, I ſhall refer the curious to his book, where they will find a great number of the moſt accurate and well conducted experiments related, to aſcertain the uſes of the Leaves of plants in vegetation.

The before-mentioned Rev. Dr. Hales, in his Treatiſe of Vegetation, ſays, it is plain from many experiments and obſervations he had before mentioned, that Leaves are very ſerviceable in this work of vegetation, by being inſtrumental in bringing nouriſhment from the lower parts, within the reach of the attraction of the growing fruit, which, like young animals, is furniſhed with proper inſtruments to ſuck it thence; but the Leaves ſeem alſo deſigned for many other noble and important ſervices; for nature admirably adapts her inſtruments, ſo as to be at the ſame time ſerviceable to many good purpoſes.

Thus the Leaves, in which are many excretory ducts in vegetables, ſeparate and carry off the redundant watery fluid, which, by being long detained, would turn rancid, and prejudicial to the plant, leaving the more nutritive parts to coaleſce; part of which nouriſhment, we have good reaſon to think, is conveyed into vegetables through the Leaves, which plentifully imbibe the dew which contain ſalt, ſulphur, &c.

For the air is full of acid and ſulphureous particles, which, when they abound much, do, by the action and reaction between them and the elaſtic air, cauſe that ſultry heat which uſually ends in lightning and thunder; and theſe new combinations of air, ſulphur, and acid ſpirit, which are conſtantly forming in the air, are doubtleſs very ſerviceable in promoting the work of vegetation; when, being imbibed by the Leaves, they may not improbably be the materials, out of which the more ſubtile and refined principles of vegetables are formed; for ſo fine a fluid as the air ſeems to be a more proper medium, wherein to prepare and combine the more exalted principles of vegetables, than the groſſer watery fluid of the ſap: and for the ſame reaſon it is likely that the moſt refined and active principles of animals are alſo prepared in the air, and thence conveyed through the lungs into the blood; and that there is plenty of theſe ſulphureo-aereal particles in the Leaves, is evident from the ſulphureous exſudations that are found in the edges of Leaves, of which bees are obſerved to make their waxen cells, as well as of the duſt of flowers. And that wax abounds with ſulphur, is plain from its burning freely, &c.

We may therefore reaſonably conclude, that one great uſe of Leaves is what has been long ſuſpected by many, viz. to perform, in ſome meaſure, the ſame office for the ſupport of the vegetable life, as the lungs of animals do for the ſupport of animal life; plants, very probably, drawing through their Leaves ſome part of their nouriſhment from the air.

LEDUM. Raii Syn. 1—142. Lin. Gen. Plant. 483. Marſh Ciſtus, or wild Roſemary.

The Characters are,

The flower has a ſmall empalement of one leaf, indented in five parts. It hath five oval, concave, ſpreading petals, and ten ſlender ſtamina the length of the petals, which ſpread open, terminated by oblong ſummits, and a roundiſh germen ſupporting a ſlender ſtyle, crowned by an obtuſe ſtigma. The germen afterward becomes a roundiſh capſule with five cells, opening at the baſe in five parts, and filled with ſmall, narrow, acute-pointed ſeeds.

This genus of plants is by Dr. Linnæus ranged in the firſt ſection of his tenth claſs, intitled Decandria Monogynia, which includes thoſe plants whoſe flowers have ten ſtamina and one ſtyle.

We have but one Species of this genus, viz.

Ledum (*Paluſtre*) foliis linearibus ſubtus hirſutis, floribus corymboſis. Flor. Suec. 341. *Ledum with very narrow leaves, hairy on their under ſide, and flowers growing in a corymbus.* Roſmarinum ſylveſtre minus noſtras. Park. Hiſt. 76. *Our ſmall wild Roſemary.*

This plant grows naturally upon moſſes and bogs in many parts of Yorkſhire, Cheſhire, and Lancaſhire, where it riſes with a ſlender ſhrubby ſtalk about two feet high, dividing into many ſlender branches, which are garniſhed with narrow leaves not much unlike thoſe of Heath. The flowers are produced in ſmall cluſters at the end of the branches, which are ſhaped like thoſe of the Strawberry-tree, but ſpread open wider at the top. Theſe are of a reddiſh colour, and appear in May, and in the natural places of their growth, are ſucceeded by ſeed-veſſels filled with ſmall ſeeds, which ripen in the autumn.

It is with great difficulty this plant is kept in a garden, for as it naturally grows upon bogs, ſo unleſs the plants have ſome ſuch ſoil and a ſhady ſituation, they will not thrive. The plants muſt be procured from the places of their growth, and taken up with good roots, otherwiſe they will not live. They cannot be propagated in gardens, but in the moſſes their roots ſpread and propagate pretty freely.

LEEKS. See Porrum.

LEGUMES, or **LEGUMENS,** are a ſpecies of plants which are called pulſe, ſuch as Peas, Beans, &c. and are ſo called, becauſe they may be gathered by the hand without cutting. Mr. Ray reckons all thoſe plants which have a papilionaceous flower, among the Legumes; but the French comprehend moſt ſorts of eſculent plants, under this general title of Legumes.

LEGUMINOUS, of or belonging to pulſe.

LEMNA. Lin. Gen. 1038. Lens Paluſtris, Duck-Meat. This is a very common plant, growing upon ſtanding waters in moſt parts of England; where, if it is not diſturbed, it will ſoon cover the whole ſurface.

LEMON-TREE. See Limon.

LENS. See Ervum.

LENTISCUS. See Pistacia.

LEONTICE. Lin. Gen. Plant. 423. Leontopetalon. Tourn. Cor. 49. tab. 484. Lion's Leaf.

The Characters are,

The empalement of the flower is made up of ſix very narrow leaves, which are alternately ſmaller and drop off. The flower has ſix oval acute petals, which are twice the length of the empalement, and ſix nectariums which are fixed by ſmall foot-ſtalks to the baſe of the petals. It has ſix ſhort ſlender ſtamina, terminated by erect ſummits. In the center is placed an oblong oval germen, ſupporting a ſhort taper ſtyle, inſerted obliquely to the germen, crowned by a ſimple ſtigma. The germen afterward becomes a globular ſwollen berry a little ſucculent, with one cell, incloſing two or three globular ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's ſixth claſs, which includes thoſe plants whoſe flowers have ſix ſtamina and one ſtyle.

The Species are,

1. Leontice (*Chryſogonum*) foliis pinnatis, petiolo communi ſimplici. Hort. Cliff. 122. *Lion's Leaf, with winged leaves having one common ſingle foot-ſtalk.* Leontopetalon foliis coſtæ ſimplici innaſcentibus. Tourn. Cor. 49. *Lion's Leaf with a ſingle foot-ſtalk to the leaves.*

2. Leontice (*Leontopetalum*) foliis decompoſitis, petiolo communi trifido. Hort. Cliff. 122. *Lion's Leaf with decompounded leaves, and a common trifid foot-ſtalk.* Leontopetalon foliis coſtæ ramoſæ innaſcentibus. Tourn. Cor. 49. *Lion's Leaf with a branching foot-ſtalk to the leaves.*

Theſe plants both grow naturally in the iſlands of the Archipelago, and alſo in the Corn fields about Aleppo, where they flower ſoon after Chriſtmas. They have large tuberous roots about the ſize of thoſe of Cyclamen, covered with a dark brown bark; the leaves ariſe upon ſlender foot-ſtalks immediately from their roots, which grow about ſix inches high; that of the firſt ſort is ſingle, having many ſmall folioli ranged along the midrib, but the footſtalks of the ſecond ſort are branched into three ſmaller; upon each of theſe are ranged ſeveral folioli or ſmall leaves, in the ſame form as the winged leaves. The flowers ſit upon naked foot-ſtalks, thoſe of the firſt ſort ſuſtain many yellow flowers, but the flowers of the ſecond are ſmaller and of a paler colour. Theſe in their native country appear ſoon after Chriſtmas, but in England they do not flower till the beginning of April, and are never ſucceeded by ſeeds here.

Both theſe plants are propagated by ſeeds, which require to be ſown ſoon after they are ripe, otherwiſe they ſeldom ſucceed; but as they are brought from diſtant countries, they ſhould be preſerved in ſand to be ſent to England. I received a few of the ſeeds from the Duke D'Ayen, which were ſent him from Aleppo, put up in ſand, and theſe came up better than any of thoſe which came over dry; for of ſeveral parcels of theſe ſeeds which I have ſown of both kinds for three years ſucceſſively, I had not more than two plants ariſe.

The plants are very difficult to preſerve in England, for the roots will not thrive in pots; and when they are planted in the full ground, the froſt frequently deſtroys them in winter, eſpecially where the roots are young. Of late years the winters have proved ſo very unfavourable, as to kill all the young roots which I had raiſed in the Chelſea garden: but before the ſevere winter in 1740, I had ſome of the roots which were planted in a ſouth-weſt border that flowered ſeveral years, and without any ſhelter ſurvived the winters; but although I covered many of thoſe roots which I had lately raiſed, yet I could not preſerve them.

The leaves of theſe plants decay about Midſummer, and the roots remain in an inactive ſtate till the following ſpring, at which time the flowers and leaves come up nearly at the ſame time.

When the ſeeds are procured from abroad, the beſt way is to ſow them as ſoon as they arrive, and cover them with glaſſes in the winter to protect them from froſt; and in the ſpring, when the plants begin to appear, they muſt have the free air admitted to them at all times when the weather is mild, otherwiſe they are very ſubject to draw up tall with weak ſtems, and their roots do not increaſe in their bulk. If the plants are not too cloſe, it will be beſt to let them remain in the place unremoved till the ſecond year; but where they are too cloſe, part of the roots may be taken up in October, and tranſplanted cloſe to a warm wall, being very careful not to diſturb the roots which are left ſtanding; and in November, before the hard froſt ſets in, it will be a good way to lay ſome old tanners bark over the ſurface of the ground, three or four inches thick, to prevent the froſt from penetrating to the roots; but this ſhould be moſt of it taken off in March, before the roots begin to puſh out their leaves; and if this is removed in part ſoon after the hard froſt is over in February, and another part three weeks or a month after, it will be better than taking it all off at the ſame time; and if a thin covering of the tan is left at the laſt over the ſurface of the ground, it will prevent the drying winds of the ſpring from drying the ground, which will be of great ſervice to the roots. Theſe roots ſhould have a dry looſe ſoil, and muſt be ſeldom removed; but when that is done, October is the beſt time, for then the roots are inactive.

LEONTODON. Lin. Gen. Plant. 817. Dens leonis. Tourn. Inſt. R. H. 468. Dandelion; in French, *Dent de Lion.*

There are four or five ſpecies of this genus, which grow naturally in the fields either in England or France, ſo are ſeldom cultivated in gardens; but as ſome people in the ſpring gather the roots out of the fields, and blanch them in their gardens for a ſallad herb, ſo I have mentioned the genus, but ſhall forbear ſaying any thing more of them, than that they are very bad weeds both in gardens and fields; ſo ſhould be rooted out before their ſeeds are ripe, otherwiſe they will ſpread to a great diſtance, as they have down adhering to them, by which they are wafted about by the wind.

LEONTOPODIUM. See Plantago.

LEONURUS. Tourn. Inſt. R. H. 187. tab. 87. Phlomis. Lin. Gen. Plant. 642. [Λεώνουρος, of Λέων, a lion, and οὐρὰ, a tail, becauſe the creſt of this flower ſeems to reſemble the tail of a lion.] Lion's Tail.

The Characters are,

The flower has a tubulous, five-cornered, permanent empalement of one leaf; the flowers have one petal, of the lip or ringent kind; the upper lip is long, cylindrical, hairy, and entire; the lower is ſhort, reflexed, and cut into three parts. It hath four ſtamina ſituated under the lower lip, two of which are ſhorter than the other; theſe are terminated by oblong compreſſed ſummits. In the bottom of the tube are ſituated four germen ſupporting a ſlender ſtyle, ſituated with the ſtamina, crowned by a bifid acute ſtigma. The germen afterward become four oblong angular ſeeds, ſitting in the empalement.

This genus of plants is ranged in the ſecond ſection of Tournefort's fourth claſs, which includes the herbs with a lip flower of one leaf, whoſe upper lip is hollowed like a ſpoon. Dr. Linnæus has joined the ſpecies of this genus to the Phlomis, and has applied this title to the Cardiaca, from which he ſeparates theſe plants, becauſe they have no punctures on their ſummits. Theſe he ranges in the firſt ſection of his fourteenth claſs, which includes the plants with a ringent (or grinning) flower, that have two long and two ſhorter ſtamina, and naked ſeeds ſucceeding, ſitting in the empalement.

The Characters are,

1. Leonurus (*Africana*) foliis lanceolatis, obtuſe ſerratis. Hort. Cliff. 312. *Lion's Tail with ſpear-ſhaped leaves which are bluntly ſawed.* Leonurus perennis Africanus, ſideritidis folio, flore Phœnicio majore. Breyn. Cent. 1. 171. *Perennial African Lion's Tail with an Ironwort leaf, and a larger ſcarlet flower.*

2. Leonurus (*Nepetæfolia*) foliis ovatis, calycibus decagonis, ſeptem dentatis, inæqualibus. Hort. Cliff. 312. *Lion's Tail with oval leaves, an empalement having ten corners, and ſeven unequal indentures.* Leonurus minor capitis Bonæ Spei, vulgò. Boerh. Ind. alt. 180. *Small Lion's Tail of the Cape of Good Hope.*

The firſt ſort is a native of Ethiopia, but has been long cultivated in the Engliſh gardens. This riſes with a ſhrubby ſtalk ſeven or eight feet high, ſending out ſeveral branches from the ſide, which are four-cornered; theſe are garniſhed with oblong narrow leaves, acutely indented on their edges; they are about three inches long, and half an inch broad, hairy on their upper ſide, and veined on their under, ſtanding oppoſite. The flowers are produced in whorls round the branches, each of the branches having two or three of theſe whorls toward their ends, ſitting very cloſe to the branches; they are of the lip kind, ſhaped ſomewhat like thoſe of the Dead Nettle, but their creſts are much longer and covered with ſhort hairs; they are of a golden colour, ſo make a fine appearance. The flowers commonly appear in October and November, and ſometimes continue till the middle of December, but are not ſucceeded by ſeeds here.

There is a variety of this ſort with variegated leaves, which is by ſome admired; but as this ſeldom produces ſo large whorls of flowers as the plain ſort, it is not ſo generally eſteemed.

The ſecond ſort is mentioned by ſeveral authors as an annual plant; they alſo ſuppoſe it to be a native of America, and believe it was brought from Surinam to Holland; but it is undoubtedly a native of the Cape of Good Hope, from whence I have two or three times received the ſeeds; and the late Dr. Boerhaave aſſured me, that he frequently received the ſeeds from that country, as alſo a painting of the plant, ſo that he made no doubt of the plant growing naturally there.

This riſes with a ſquare ſhrubby ſtalk about three feet high, ſending out ſeveral four-cornered branches, which are garniſhed with oval crenated leaves, rough on their upper ſide like the Dead Nettle, but veined on the under, which is of a pale green: theſe are placed oppoſite by pairs, as are alſo their branches. The flowers come out in whorls round the branches, in like manner as the former, but are not ſo long nor ſo deep coloured; they appear at the ſame ſeaſon with the firſt, and continue as long in beauty.

Both theſe ſorts are propagated by cuttings in Europe, for they do not produce any ſeeds here. If the cuttings are planted in July, after the plants have been ſo long expoſed to the open air as to harden the ſhoots, they will take root very freely. They ſhould be planted in a loamy border to an eaſt aſpect, and if they are covered cloſely with a bell or hand-glaſs to exclude the air, and ſhaded from the ſun, it will forward their putting out roots; but when they begin to ſhoot, the glaſſes ſhould be raiſed to admit the free air, to prevent their drawing up weak, and by degrees they muſt be expoſed to the open air. As ſoon as they have taken good root they muſt be taken up, and each planted in a ſeparate pot filled with ſoft loamy earth, and placed in the ſhade till they have taken new root; then they may be removed to a ſheltered ſituation, where they may remain till October, when they muſt be removed into the green-houſe, and afterward treated as the Myrtle, and other hardy green-houſe plants, obſerving to water the firſt ſort plentifully.

LEPIDIUM. Tourn. Inſt. R. H. 215. tab. 103. Lin. Gen. Plant. 718. Dittander, or Pepperwort.

The Characters are,

The empalement of the flower is compoſed of four oval concave leaves, which fall off. The flower has four oval petals placed in form of a croſs, which are much larger than the empalement, and ſix awl-ſhaped ſtamina the length of the empalement, two of which are ſhorter than the other, terminated by ſingle ſummits. In the center is ſituated a heart-ſhaped germen, ſupporting a ſingle ſtyle, crowned by an obtuſe ſtigma. The germen afterward turns to a ſpear-ſhaped ſeed-veſſel with two cells, divided by an intermediate partition, containing oblong ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's fifteenth claſs, intitled Tetradynamia ſiliculoſa, the flower having four long and two ſhorter ſtamina, and the ſeeds being included in ſhort pods.

The Species are,

1. LEPIDIUM (*Latifolium*) foliis ovato-lanceolatis integris ſerratis. Hort. Cliff. 330. *Dittander with entire, oval, ſpear-ſhaped leaves, which are ſawed.* Lepidium latifolium. C. B. P. 97. *Broad-leaved Dittander.*
2. LEPIDIUM (*Arvenſe*) foliis lanceolatis amplexicaulibus dentatis. Hort. Cliff. 331. *Dittander with ſpear-ſhaped indented leaves which embrace the ſtalks.* Lepidium humile, incanum arvenſe. Tourn. Inſt. R. H. 216. *Low hoary Dittander of the fields.*
3. LEPIDIUM (*Chalepenſe*) foliis ſagittatis ſeſſilibus dentatis. Amœn. Acad. 4. p. 321. *Dittander with arrow-ſhaped indented leaves ſitting cloſe to the ſtalks.* Lepidium humile minus incanum, Alepicum. Tourn. Inſt. 216. *Low Dittander of Aleppo with leſs hoary leaves.*
4. LEPIDIUM (*Iberis*) floribus diandris tetrapetalis, foliis inferioribus lanceolatis ſerratis, ſuperioribus linearibus integerrimis. Flor. Leyd. Prod. 334. *Dittander with flowers having four petals and two ſtamina, whoſe under leaves are ſpear-ſhaped and ſawed, and the upper narrow and entire.* Lepidium gramineo folio ſive, Iberis. Tourn. Inſt. 216. *Dittander with a Graſs leaf, or Iberis.*
5. LEPIDIUM (*Perfoliatum*) foliis caulinis pinnato-multifidis, ramiferis cordatis, amplexicaulibus integris. Hort. Cliff. 331. *Dittander with lower leaves wing-pointed, and thoſe on the branches heart-ſhaped, entire, and embracing the ſtalks.* Thlaſpi verum Dioſcoridis. 1 Zan. Hiſt. 193. *The true Mithridate Muſtard of Dioſcorides.*
6. LEPIDIUM (*Virginicum*) floribus ſubtriandris tetrapetalis, foliis linearibus pinnatis. Lin. Gen. Plant. 645. *Dittander with flowers having four petals, chiefly with three ſtamina, and very narrow winged leaves.* Iberis humilior annua Virginiana ramoſior. Mor. Hiſt. 2. p. 311. *Lower, annual, branching Sciatica Creſs of Virginia.*
7. LEPIDIUM (*Lyratum*) foliis lyratis criſpis. Lin. Sp. Plant. 644. *Dittander with curled lyre-ſhaped leaves.* Lepidium Orientale naſturtii criſpi folio. Tourn. Cor. 15. *Eaſtern Dittander with a leaf like curled Creſs.*
8. LEPIDIUM (*Nudicaule*) ſcapo nudo ſimpliciſſimo, floribus tetrandris. Lœfl. It. 155. *Dittander with a ſingle naked ſtalk, and flowers with four ſtamina.* Naſturtium minimum vernum, foliis tantum circa radicem. Magn. Montp. 187.
9. LEPIDIUM (*Petræum*) foliis pinnatis integerrimis, petalis emarginatis calyce minoribus. Flor. Suec. *Dittander with entire winged leaves, and indented petals to the flowers which are ſmaller than the empalement.* Naſturtium pumilum vernum. C. B. P. 105.
10. LEPIDIUM (*Sativum*) floribus tetradynamis, foliis oblongis multifidis. Vir. Cliff. 63. *Dittander with ſix ſtamina in the flowers, and oblong leaves with many points.* Naſturtium hortenſe. *Garden Creſs.*

12. LEPIDIUM (*Ruderale*) floribus diandris apetalis, foliis radicalibus dentato-pinnatis, ramiferis linearibus integerrimis. Flor. Suec. 534. *Dittander with two ſtamina in the flowers, fugacious petals, the bottom leaves indented, and thoſe on the branches linear and entire.* Naſturtium ſylveſtre Oſyridis folio. C. B. P. 105.
13. LEPIDIUM (*Bonarienſe*) floribus diandris tetrapetalis, foliis omnibus pinnato-multifidis. Lin. Sp. 901. *Dittander with two ſtamina and four petals to the flowers, and all the leaves wing-pointed.* Thlaſpi Bonarienſe multiciſſum flore inviſibili. Hort. Elth. 286.

The firſt ſort grows naturally in moiſt places in many parts of England, ſo is now ſeldom cultivated in gardens. It hath ſmall, white, creeping roots, by which it multiplies very faſt, ſo as to render it difficult to eradicate the plant, after it has grown long in any place; the lower leaves are oval, ſpear-ſhaped, about three inches long, and one and a half broad toward the baſe, ſawed upon the edges, having long footſtalks. The ſtalks riſe two feet high, they are ſmooth, and ſend out many ſide branches; the leaves upon the ſtalks are longer, narrower, and more acute-pointed than the lower, and are not ſawed on their edges. The flowers grow in cloſe bunches toward the top of the branches, which come out from the ſide; they are ſmall, and are compoſed of four ſmall white petals, which appear in June and July, and the ſeeds ripen in the autumn. The whole plant has a hot biting taſte like Pepper, and the leaves have been often uſed by the country people to give a reliſh to their viands inſtead of Pepper, from whence it had the appellation of Poor Man's Pepper.

This plant is eaſily propagated, for every piece of the root will grow and multiply wherever it is planted, ſo will become troubleſome to root out after growing for ſome time in a garden. The leaves of this plant bruiſed and mixed with hog's lard, and applied as a cataplaſm to the hip, help the ſciatica; and chewed in the mouth, cauſe a great defluxion of rheum, ſo is ſaid to help ſcrophulous tumours in the throat.

The ſecond ſort grows naturally in Auſtria and Italy; this hath a fleſhy fibrous root, from whence ariſe ſeveral weak ſtalks about a foot and a half high, which are garniſhed with ſpear-ſhaped leaves, three inches long and one and a half broad, deeply cut in upon the edges; theſe are ſmooth, a little hoary, and embrace the ſtalks with their baſe; the flowers are ſmall, white, and grow in looſe bunches at the end of the branches. They flower from June till the beginning of September, and the ſeeds ripen in the autumn.

This is a perennial plant, which propagates very faſt by its roots, and is ſeldom admitted into gardens.

The third ſort grows naturally about Aleppo; this hath creeping roots, which extend to a great diſtance, ſo will ſoon ſpread over a large piece of ground. The leaves of this are longer and narrower than thoſe of the former, and are leſs hoary; the flowers grow in looſe bunches at the end of the branches; they are ſmall and white like thoſe of the firſt. This is a hardy perennial plant, which propagates by its creeping roots in as great plenty as either of the former.

The fourth ſort grows naturally in the ſouth of France, Italy, and Sicily, but is preſerved in ſome Engliſh gardens for variety. This hath a long fleſhy root, which runs deep into the ground, and ſends out many oblong leaves, which are ſawed on their edges, and ſpread flat on the ground; the ſtalks are ſlender, ſtiff, and branch out horizontally on every ſide; they riſe about two feet high, and are garniſhed with very narrow entire leaves. The flowers come out in cloſe ſmall cluſters at the ends of the branches; they are white, and appear in June and July, and the ſeeds ripen in the autumn. If the ſeeds are permitted to ſcatter, the plants will come up early in the ſpring, and require no other care but to keep them clean from weeds; the roots will abide ſeveral years if they are in a dry ſoil. This plant is alſo commended for its virtues in ſciaticas, if bruiſed and mixed with hog's lard as the firſt, and from its virtues it obtained the title of Sciatica Creſs.

The fifth ſort grows naturally in Perſia and Syria; this is ſuppoſed to be the true Mithridate Muſtard of Dioſcorides. It is an annual plant, whoſe lower leaves are winged, and finely cut into many ſegments; the ſtalks riſe a foot high, dividing into many ſlender branches, which are garniſhed with heart-ſhaped leaves that are entire, and embrace the ſtalks with their baſe. The flowers grow in long looſe ſpikes from the end of the branches; they are ſmall, yellow, and appear in June and July, and the ſeeds ripen in September, ſoon after which the plant decays.

The ſeeds of this plant ſhould be ſown in the autumn, for thoſe which are ſown in the ſpring ſeldom flower the ſame year, and are often killed by the froſt in winter; whereas thoſe which are ſown in the autumn, or the plants that riſe from ſcattered ſeeds, will always flower about Midſummer, and the ſeeds ripen in Auguſt and September following. The plants require no other care but to thin them, and keep them clean from weeds.

The ſixth ſort is an annual plant, which grows naturally in Virginia, and alſo in all the iſlands of the Weſt-Indies, where the inhabitants gather the leaves, and eat them in their ſallads, as we do the Garden Creſs.

The lower leaves of this ſort are three inches long and one broad, ſawed on their edges, and are of a light green, with a biting taſte like Creſs. The ſtalk riſes a foot and a half high, ſending out a great number of ſmall ſide branches, which are garniſhed with narrow leaves regularly ſawed on their edges, ſo as to reſemble winged leaves; theſe ſit cloſe to the branches. The flowers are produced at the end of the branches in looſe ſpikes; they are ſmall and white, and are ſucceeded by roundiſh or heart-ſhaped compreſſed ſeed-veſſels, which have a border round them. It flowers in June and July, and the ſeeds ripen in the autumn; this ſort is eaſily propagated by ſeeds, which may be ſown upon an open bed in April, where the plants are deſigned to remain; and when they come up, they will require no other care but to thin them where they are too cloſe, and keep them conſtantly clean from weeds; or if the ſeeds are permitted to ſcatter in the autumn, the plants will come up very well, and may be treated in the ſame way as the other.

The ſeventh ſort grows naturally in Aſia, and alſo in Spain, from whence I have received the ſeeds. This is a biennial plant; the lower leaves which ſpread on the ground, are near two inches long, and about half an inch broad, indented on both ſides in ſhape of a lyre, and curled on the edges; the ſtalks riſe a foot high, and divide into a great number of ſlender branches, garniſhed with ſmall oblong leaves, which are cut on their ſides, and a little curled on their edges; the ſtalks and leaves are of a gray colour, inclining toward hoarineſs. The flowers are produced in cluſters at the end of the branches; they are very ſmall and white, appearing in July, and are ſucceeded by roundiſh bordered ſeed-veſſels, which are compreſſed, and have two cells each, containing two ſmall oblong ſeeds, which are ripe in the autumn.

This ſort may be propagated by ſeeds in the ſame manner as the former; or if the ſeeds are permitted to ſcatter in the autumn, the plants will come up without care, and ſhould be treated in the ſame way as the former ſort; but this does not flower till the ſecond year, ſo the plants ſhould be left farther aſunder.

The eighth ſort grows naturally about Montpelier. It is a ſmall annual plant, having a few wing-pointed leaves which ſpread on the ſurface of the ground; between which ariſes a naked ſtalk two or three inches high, ſupporting five or ſix ſmall white flowers, each having four petals placed croſswiſe, and four ſtamina placed near the ſtyle; the germen afterward becomes a ſhort capſule, including four or five roundiſh ſeeds.

If the ſeeds of this ſort are ſown in the autumn, the plants will flower in April and their ſeeds ripen in May; which, if permitted to ſcatter, the plants will come up in autumn, and require no other care but to thin them where they are too cloſe, and weed them.

The ninth ſort is alſo a low annual plant, which grows naturally on Putney-heath; the leaves of this are winged and entire, theſe are placed near the ground; the flower-ſtalks riſe two inches high, ſupporting a few white flowers, whoſe petals are leſs than the empalement, and are indented at their points. This flowers in May and June, and if their ſeeds are permitted to ſcatter, the plants will come up as the former.

The tenth ſort is the Garden Creſs, ſo much uſed in winter and ſpring ſallads, and being ſo well known requires no deſcription. There are three varieties of this, one with broad leaves, another with curled leaves, and the common ſort which is uſed; the ſeeds of this ſhould be ſown in drills pretty cloſe, in winter, on moderate hot-beds, but in ſpring and autumn on borders, and will ſoon be fit for uſe; therefore ſhould be cut while young, otherwiſe it will be too rank.

The eleventh ſort is a low ſhrubby plant, garniſhed with entire awl-ſhaped leaves, which are very narrow; theſe are placed alternately on the ſtalks; the foot-ſtalks of the flowers proceed from the wings, and alſo terminate the ſtalks; the flowers are white, and ſhaped like thoſe of the other ſpecies.

This ſort may be propagated by ſeeds or cuttings; the ſeeds ſhould be ſown in the ſpring on a bed of light earth, in the open air; and when the plants are fit to tranſplant, a few of them ſhould be planted in pots, which may be ſheltered in winter under a common frame; for in ſharp winters, thoſe plants which are expoſed in the open air are frequently killed: the remaining plants ſhould be planted in a ſheltered ſituation in a dry rubbiſhing ground, where they will grow ſlowly, ſo will become more ſhrubby, and in leſs danger of ſuffering by cold.

The twelfth ſort is an annual plant, which grows naturally in ſeveral parts of England, ſo is rarely preſerved in gardens, being a plant of no great beauty or uſe; yet I have known it eaten in ſallads, though the taſte is very rank. The plants, when young, have ſome reſemblance to the Swine's Creſs. The ſtalks riſe eight or ten inches high, ſupporting a number of ſmall white flowers, ſhaped like thoſe of the other ſpecies, which are ſucceeded by ſeeds like thoſe of the Garden Creſs, which, if permitted to ſcatter, will abundantly ſupply the place with young plants.

The thirteenth ſort grows naturally in many warm countries, for it has come up in the earth which came from the Braſils, and from ſeveral parts of America, ſo that it may be found in many other parts. The leaves and ſtalks are much like thoſe of the Garden Creſs, but are more divided, and differ in ſmell and taſte from it: the petals of the flowers are ſo ſmall as to be almoſt imperceptible, and there appears but two ſtamina in each.

This ſort is only cultivated in botanic gardens for variety; the ſeeds ſhould be ſown on a moderate hot-bed in the ſpring, and when the plants have obtained ſtrength, they may be tranſplanted on a warm border, where they will flower and perfect their ſeeds.

LEPIDOCARPODENDRON. See PROTEA.

LETTUCE. See LACTUCA.

LEUCANTHEMUM. See ANTHEMIS.

LEUCOJUM. Lin. Gen. Plant. 363. Narciſſo-leucojum. Tourn. Inſt. R. H. 387. tab. 208. [Λευκόϊον, of λευκὸν, white, and Ἴον, a Violet; i. e. White Violet,] Snowdrop; in French, *Perce-neige.*

The CHARACTERS are,

It hath an oblong, obtuſe, compreſſed ſpatha or ſheath, which opens on the ſide. The flower is of the ſpreading bell ſhape, cut into ſix parts, which join at their baſe. It hath ſix ſhort briſtly ſtamina, terminated by oblong, obtuſe, four-cornered ſummits, which are erect. The roundiſh germen is ſituated under the flower, ſupporting a ſtyle which is thick and obtuſe at the top, crowned by an erect briſtly ſtigma. The germen afterward becomes a turbinated capſule with three cells, opening with three valves, and filled with roundiſh ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's ſixth claſs, which includes the plants whoſe flowers have ſix ſtamina and one ſtyle.

The SPECIES are,

1. LEUCOJUM (*Vernum*) ſpathâ uniflorâ, ſtylo clavato. Lin. Sp. Plant. 289. *Snowdrop with a ſheath incloſing one flower, with a key-ſhaped ſtyle.* Narciſſo-leucojum vulgare. Tourn. Inſt. R. H. 387. *Common great Snowdrop.*
2. LEUCOJUM (*Æſtivum*) ſpathâ multiflorâ, ſtylo clavato. Lœfl. Lin. Sp. Plant. 289. *Snowdrop with many flowers in a ſheath, and a key-ſhaped ſtyle.* Narciſſo-leucojum pratenſe multiflorum. Tourn. Inſt. R. H. 387. *Meadow Snowdrop with many flowers, commonly called the tall late Snowdrop.*

The firſt ſort grows naturally in Switzerland and Germany, as alſo upon the mountains near Turin. This hath an oblong bulbous root, ſhaped like that of the Daffodil, but ſmaller; the leaves are flat, of a deep green, four or five in number, broader and longer than thoſe of the ſmall Snowdrop; between theſe ariſe an angular ſtalk near a foot high, which is naked, hollow, and channelled; toward the top comes out a ſheath, which is whitiſh, opening on the ſide, out of which come two or three white flowers, hanging upon ſlender foot-ſtalks; theſe have but one petal, which is cut into ſix parts almoſt to the bottom, which are much larger than thoſe of the ſmall Snowdrop, and the ends of the ſegments of the petal are tipped with green, where they are of a thicker ſubſtance than in any other part. Theſe flowers appear in March, ſoon after thoſe of the ſmall ſort; they have an agreeable ſcent, not much unlike that of the flowers of Hawthorn; after the flower is paſt, the germen which is ſituated below the flower, ſwells to a Pear-ſhaped capſule with three cells, incloſing ſeveral oblong ſeeds.

The leaves of this ſort decay toward the end of May, after which time the roots may be taken up and tranſplanted, for they ſhould not be long kept out of the ground. It is propagated here by offſets, which the roots put out pretty plentifully when they are in a ſituation agreeable for them, and when they are not too often removed. They ſhould have a ſoft, gentle, loamy ſoil, and an expoſure to the eaſt; the roots ſhould be planted ſix inches aſunder, and four or five inches deep, and muſt not be tranſplanted oftener than every third year.

The ſecond ſort is generally known by the title of late, or tall Snowdrop; this grows naturally in the meadows near Piſa in Italy, in Hungary, and alſo near Montpelier.

The root of this ſort is nearly as large as thoſe of the common Daffodil, and are very like them in ſhape; the leaves alſo are not unlike thoſe of the Daffodil, and are more in number than thoſe of the other ſort; they are of a pale green, and keel-ſhaped at the bottom, where they fold over each other, and embrace the ſtalk, which riſes a foot and a half high; at the top is ſituated a ſpatha (or ſheath) which opens on one ſide, and lets out three or four flowers, which hang downward, upon pretty long foot-ſtalks; theſe are cut into ſix oval concave ſegments almoſt to the bottom, and are of a clear white, with a large green tip to each ſegment, which is of a thicker conſiſtence than any other part of the petal; within are ſituated ſix awl-ſhaped ſtamina, with oblong yellow ſummits, ſtanding erect round a very ſlender ſtyle, crowned by an obtuſe ſtigma. Theſe flowers appear the latter end of April or the beginnning of May, and as all flowers in each ſheath do not come out together, but following each other, ſo there is a ſucceſſion of them for three weeks or longer, in cool weather. The flowers are ſucceeded by large triangular ſeed-veſſels, having three cells, each containing two rows of ſeeds. This ſort is generally propagated in England by offſets, for the plants raiſed by ſeeds will not come to flower in leſs than four years; and as the roots put out offſets in plenty, ſo that is the more expeditious method. Theſe roots may be treated in the ſame way as the firſt ſort, and ſhould have a ſoft loamy ſoil, and be expoſed only to the morning ſun, where they will flower ſtronger, and continue longer in beauty, than when they are in an open ſituation, though they will thrive in almoſt any ſoil or ſituation.

LEUCOJUM INCANUM. } See CHEIRANTHUS.
LEUCOJUM LUTEUM. }

LEUCOJUM BULBOSUM. See GALANTHUS.

LEVEL, a mathematical inſtrument ſerving to draw a line parallel to the horizon, not only for various uſes in maſonry, &c. but alſo to meaſure the difference of aſcent and deſcent between ſeveral places, for the conveying of water, draining of fens, &c.

A water Level ſhews the horizontal line, by means of a ſurface of water, or other liquid, founded on this principle, That water always naturally places itſelf level.

The moſt ſimple inſtrument for this uſe is made of a long wooden trough, or canal, whoſe ſides are parallel to its baſe, ſo that, being equally filled with water, the ſurface thereof ſhews the line of Level.

This Level is alſo made with two cups fixed to the two ends of a pipe three or four feet long, about an inch in diameter; by means whereof, the water communicates from the one to the other cup, and this pipe being moveable on its ſtand, by means of a ball and ſocket, when the two cups become equally full of water, the two ſurfaces mark the line of Level.

Inſtead of cups, this inſtrument may be made with two ſhort cylinders of glaſs three or four inches long, faſtened to each end of the pipe with wax or maſtich; then the pipe, being filled either with common or coloured water, will ſhew itſelf through the cylinder, by means of which the line of Level is determined, the height of the water, with reſpect to the center of the earth, being always the ſame in both cylinders. This Level is very commodious in levelling ſmall diſtances.

If you would level any piece of ground that you can ſee from ſide to ſide, or from the middle to any ſide, ſet up your inſtrument in the middle of it, whether it be a water Level, or a ground Level with ſights; place it ſo high, that you may ſee over the higheſt part of the ground half a foot or a foot; then ſet up a ſtake in the middle, ſo that the top may be exactly level with the ſights, and another ſtake on the higheſt ſide, the top of which muſt be level with the middle ſtake; then either turn the Level, or look-back ſight, and ſet up another ſtake on the lower ground level with the two firſt; then you will have three ſtakes ſtanding in a Level.

Then keeping your Level true to the middle ſtake, turn it till it makes right angles with the three ſtakes, and ſet up two ſtakes on each ſide one Level with thoſe three, then you will have five ſtakes in two lines ſet true level.

If the ground be large, you may ſet up two rows more by the Level, but five ſtakes are enough in a ſmall ground.

When this is done, you may lay your Level aſide, and look over the head of one to the head of another, and cauſe the perſon who aſſiſts you to put down ſtakes between two and two, till you have ſet as many ſtakes level in the ground as you think convenient; or you may uſe a rule, which being placed level with the head of the ſtake, you may look over that to the head of the other, and put ſtakes down between you and the other ſtake, to what number you pleaſe.

The ground being thus ſtaked out with all the ſtakes heads level, and half a foot higher than the higheſt ground, in ſome grounds the middle ſtake, and the ſtakes in the croſs line, will be the Level line the ground muſt be brought to; that is, abating the hill, and filling up the low ſide to the Level of the middle. But if the ground be very uneven, then you muſt meaſure over all the ſtakes, and take them middle high for their mean of Level, and, by the rule of three, proportion your ground to that.

As for inſtance: If a valley be ten poles in length, and two feet in depth from the ſtrait line, and there be a hill five poles long; how many feet deep muſt a perſon ſink thoſe five poles to fill up the valley? This queſtion may be reſolved by the inverſe or back rule of three, and will ſtand thus: As 5 to 2, ſo is 10 to 4.

5 —— 2 —— 10
2
5)20(4

So that a perſon muſt go four feet deep in ſuch a hill to make good ſuch a valley.

If you are to abut the top of the hill four feet deep, and two poles from the top of that hill, theſe four feet are to come out.

To perform this, ſet up a ſtake on the top of a hill two or three feet above ground, and another of the ſame height where the depth comes out, ſet down a ſtake three rods from that, till the head comes to be in a line with theſe two, and at that ſtake you muſt be one foot deep.

At ſix poles ſtake down another as before, and there you muſt be two feet deep: then ſtake down another at nine poles, and there you muſt be three feet deep, and you may ſet more ſtakes at equal diſtances, which will direct you ſo as that you cannot go amiſs.

LEVITY is the privation or want of weight in any body, when compared with another which is heavier, in which ſenſe it is oppoſed to gravity.

The ſchoolmen maintain, that there is ſuch a thing as poſitive and abſolute Levity, and impute this to the riſe and emergency of bodies lighter in ſpecie than the fluids wherein they riſe.

But, beſides that the common ſenſe of mankind diſcovers, that Levity is only a relative term, we find that all bodies tend towards the earth, ſome ſlower, and ſome faſter, in all fluids or mediums, whether water, air, &c.

Thus cork is ſaid to be lighter than gold, becauſe under equal dimenſions of bulk the gold will ſink in, and the cork ſwim upon the water.

Archimedes has demonſtrated, That a ſolid body will float any where in a fluid of the ſame ſpecific gravity, and that a lighter body will keep above a heavier.

The reaſon of this is, becauſe bodies falling towards the earth, thoſe which have a like number of equal parts, have equal gravity, ſince the gravity of the whole is the ſum of the gravity of all its parts.

Now, two bodies having an equal number of equal parts, if under the ſame dimenſions there are no intervals deſtitute of matter; whence it follows, that as no portion of matter is ſo ſmall, but that body wherein it is contained may be wholly divided into parts equally ſmall, there can be no reaſon for the deſcent of theſe, which will not hold equally for the deſcent of that.

Hence it may be concluded, that thoſe bodies which do not equally gravitate under the ſame dimenſions, do not contain the ſame equal portions of matter, and therefore when we ſee, that a cube of gold ſubſides in water, at the ſame time that an equal bulk of cork ſwims upon it, it is evident, that the gold muſt have a greater number of equal parts of matter under the ſame bulk than the cork, or the cork muſt have a greater number of vacuities than the gold, and that there are alſo in the water a greater number of vacuities than in the gold.

Hence we have a clear idea both of denſity or gravity, and of Levity, and know, that in a ſtrict ſenſe the latter cannot be accounted any thing poſitive, but a mere negation, or abſence of body, which determines that body to be lighter than another which contains more matter.

LICHEN. Liverwort.

There being two ſorts of this plant which are uſed in medicine, and one of thoſe being accounted a ſovereign remedy for the bite of mad dogs, I thought it would not be improper to mention them here, though they are plants which cannot be propagated by any method, except by paring up the turf of Graſs whereon they grow, and laying it down on ſome moiſt ſhady place, where, if the turf takes root, and thrives, the plants will ſpread and do well.

The two SORTS are,

1. LICHEN (*Petræus*) petræus latifolius, ſive Hepatica fontana. C. B. P. *Common broad-leaved Liverwort.*
2. LICHEN (*Officinarum*) terreſtris cinereus. Raii Syn. *Aſh-coloured Ground Liverwort.*

The firſt ſort grows on the ſides of wells, and in moiſt ſhady places, not only on the ground, but on ſtones, bricks, or wood. Of this there are ſeveral varieties, which are diſtinguiſhed by the curious in botany; but as they are plants of no uſe, I ſhall not enumerate them.

The ſecond ſort (which is uſed to cure the bite of mad dogs) grows on commons and open heaths, where the Graſs is ſhort, and the ground almoſt bare, in moſt parts of England, eſpecially on declivities, and on the ſides of pits. This ſpreads on the ſurface of the ground, and, when in perfection, is of an Aſh-colour, but as it grows old, it alters, and becomes of a dark colour. This is often carried into gardens with the turf which is laid for walks and ſlopes, and where the ſoil is moiſt and cool, it will ſpread, and be difficult to deſtroy, ſo that it renders the Graſs unſightly; but this is the only method yet known to have it grow in gardens, where it is deſired.

This is eſteemed a ſovereign remedy for the bite of mad dogs, and hath been for many years uſed with great ſucceſs. It was communicated to the Royal Society by Mr. George Dampier, whoſe uncle had long uſed this plant, to cure the bite of mad dogs on men and animals, with infallible ſucceſs. The method of taking it he has delivered as followeth: "Take of the herb, and dry it either in an oven, by the fire, or in the ſun; then powder it, and paſs it through a fine ſieve; mix this with an equal quantity of fine powdered pepper. The common doſe of this mixture is four ſcruples, which may be taken in warm milk, beer, ale, or broth." He alſo adviſes, that the part bitten be well waſhed, as alſo the clothes of the perſon who was bit, leſt any of the ſnivel, or drivel of the mad dog ſhould remain. If the perſon bitten be full grown, he adviſes, that he be blooded before the medicine is taken, and to uſe the remedy as ſoon after the bite as poſſible, as alſo to repeat the doſe two or three ſeveral mornings faſting.

LIGHT is uſed in various ſenſes: 1. Sometimes it ſignifies that ſenſation which is occaſioned in the mind by the view of luminous bodies.

2. For thoſe properties in thoſe bodies, whereby they are fitted to excite thoſe ſenſations in us.

3. A certain action of the luminous body on the medium between that and the eye, by the means of which the one is ſuppoſed to act on the other, and this is called ſecondary Light, or derived Light, in diſtinction to that of luminous bodies, which is called primary or innate Light.

As to the phænomenon of light, philoſophers have explained it ſeveral ways; Ariſtotle by ſuppoſing ſome bodies to be tranſparent, as air, water, ice, &c. The Carteſians have conſiderably refined upon this notion of Light, and own, that Light, as it exiſts in the luminous body, is nothing elſe but a power or faculty of exciting in us a very clear and vivid ſenſation; and Father Malebranche explains the nature of Light by a ſuppoſed analogy between it and ſound, the latter of which is allowed to be produced by the ſhaking or vibration of the inſenſible parts of the ſonorous body.

But the greateſt diſcoveries into this wonderful phænomenon have been made by Sir Iſaac Newton, that the primary light conſiſts wholly in a certain motion of the particles of the lucid body, whereby they do not propel any fictitious matter ſuppoſed to be lodged in the hidden pores of tranſparent bodies, but throw off from the luminous body certain very ſmall particles, which are emitted every way with great force.

And the ſecondary or derived Light, not in a conatus, but in a real motion of theſe particles receding every way from the luminous body in right lines, and with an incredible velocity.

For it has been demonſtrated by Mr. Reaumur, from the obſervation on the ſatellites of Jupiter, that the progreſs of Light from the ſun to our earth is not above ten minutes, and therefore, ſince the earth is at leaſt 10,000 of its own diameters diſtant from the ſun, Light muſt run 10,000 of thoſe diameters in a minute, which is above 100,000 miles in a ſecond.

And if a bullet, moving with the ſame celerity with which it leaves the muzzle of a cannon, requires twenty-five years to paſs from the earth to the ſun, as Mr. Huygens has computed; then the velocity of Light will be to that of a cannon ball, as twenty-five years is to ten minutes, which is above 10,000 to 1: ſo that the particles of Light move above a million of times ſwifter than a cannon ball, from which rapidity of motion very ſtrange effects may be produced; but Sir Iſaac Newton has ſhewn, paſt contradiction, that the Light of the ſun is near ſeven minutes in its paſſage to the earth, which is the ſpace of 50,000,000, a velocity 10,000,000 times greater than that wherewith a ball flies out of the mouth of a cannon.

Sir Iſaac Newton alſo obſerves, that bodies and Light act mutually on one another: bodies on Light, in emitting, reflexing, refracting, and inflecting it, and Light on bodies, by heating them, and putting their parts into a vibrating motion, wherein heat principally conſiſts; for he obſerves, that all fixed bodies, when heated beyond a certain degree, emit Light and ſhine, which ſhining, &c. appears to be owing to the vibrating motion of the parts, and all bodies abounding in earthy and ſulphureous particles, if they be ſufficiently agitated emit Light, which way ſoever the agitation be effected.

The ſame great author obſerves, that there are but three affections of Light wherein the rays differ, viz. refrangibility, reflexibility, and colour; and thoſe rays which agree in refrangibility, agree alſo in the other two, whence they may be well defined homogeneal. Again, the colours exhibited by homogeneal Light, he calls homogeneal colours, and thoſe produced by heterogeneal Light, heterogeneal colours; from which definitions he advances ſeveral propoſitions:

1. That the ſun's Light conſiſts of rays differing by indefinite degrees of refrangibility.

2. That rays, which differ in refrangibility, when parted from one another, do proportionably differ in the colours which they exhibit.

3. That there are as many ſimple and homogeneal colours, as there are degrees of refrangibility, for to every degree of refrangibility belongs a different colour.

4. Whiteneſs, in all reſpects, like that of the ſun's immediate Light, and of all the uſual objects of our ſenſes, cannot be compounded of ſimple colours, without an indefinite variety of them, for to ſuch a compoſition there are required rays endued with all the indefinite degrees of refrangibility, which infer as many ſimple colours.

5. The rays of Light do not act one on another in paſſing through the ſame medium.

6. The rays of Light do not ſuffer any alteration of their qualities from refraction, nor from the adjacent quieſcent medium.

7. There can be no homogeneal colours produced out of Light by refraction, which are not commixed in it before, ſince refraction changes not the qualities of the rays, but only ſeparates thoſe that have divers qualities by means of their different refrangibility.

8. The ſun's Light is an aggregate of homogeneal colours, whence homogeneal colours may be called primitive or original.

Hence proceeds the whole theory of colours in plants and flowers.

Thoſe parts, v. g. which are the moſt refrangible, conſtitute Violet colour, the dimmeſt and moſt languid of all colours.

And, on the contrary, thoſe particles that are the leaſt refrangible, conſtitute a ray or a red colour, which is the brighteſt and moſt vivid of all colours; the other particles being diſtinguiſhed into little rays, according to their reſpective magnitudes and degrees of refrangibility, excite intermediate vibrations, and ſo occaſion the ſenſations of the intermediate colours. See Sir Iſaac Newton's Doctrine of Colours.

Perhaps theſe obſervations of Light may to ſome perſons ſeem foreign to the ſubject matter of this book, yet, if thoroughly underſtood might probably be found very uſeful. The learned and curious enquirer into the buſineſs of vegetation, the Rev. Dr.

Hales, in his treatiſe on that head, does, upon the query put by Sir Iſaac Newton [" Are not groſs bodies and Light convertible into one another? And " may not bodies receive much of their activity " from the particles of Light which enter their compoſition? The change of bodies into Light, and " of Light into bodies, is very conformable to the " courſe of nature, which ſeems delighted with tranſmutations,"] add this query, " And may not " Light alſo, by freely entering the expanded ſurfaces of leaves and flowers, contribute much to the " ennobling the principles of vegetables?"

That Light has been found to be of infinite ſervice to the growth of vegetables, has been fully proved by many experiments: 1. By painting the walls of the inſide of a green-houſe black, whereby there will be no reflected rays of Light, when the weather becomes ſo cold, as that the ſhutters to the windows have been obliged to be kept ſhut a few days, the leaves of thoſe plants which have been placed therein have dropped off.

And plants which have been placed in dark rooms, have been found to do the ſame. The earthing up plants to blanch them, whereby they become tender, and better for uſe; yet if theſe are not uſed, when properly blanched, will ſoon decay: the like will happen if plants are covered cloſe, ſo as no Light can come to them, they will ſoon grow pale and ſicken, and afterward decay.

How much the fine racy flavour of fruits is owing to Light is hard to ſay, but from a few experiments it appears, moſt of their rich juices are beholden to Light for their excellence; therefore we may truly aver, that Light is as neceſſary to promote vegetation as for animal œconomy.

LIGUSTICUM. Tourn. Inſt. R. H. 323. tab. 171. Lin. Gen. Plant. 308. [takes its name of Liguria, becauſe this plant, in old time, grew in greateſt plenty near a river of Genoa, called Liguria.] Lovage; in French, *Livêche.*

The CHARACTERS are,

It hath an umbellated flower. The general umbel is compoſed of ſeveral ſmaller, which are alſo compoſed of other yet ſmaller. The general umbel has an involucrum compoſed of ſeven unequal leaves. The perianthium of the flower is indented in five parts, ſitting upon the germen. The flower hath five equal petals, which are inflexed at their points, and keel-ſhaped within. It hath five hairy ſtamina, which are ſhorter than the petals, terminated by ſimple ſummits. The germen, which is ſituated under the flower, ſupports two ſimple ſtyles, crowned by ſimple ſtigmas. The germen afterward turns to an oblong fruit, divided into two parts, which is angular and channelled, containing two oblong ſmooth ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's fifth claſs, which contains thoſe plants whoſe flowers have five ſtamina and two ſtyles.

The SPECIES are,

1. LIGUSTICUM (*Leviſticum*) foliis multiplicibus, foliolis ſupernè inciſis. Hort. Cliff. 97. *Lovage with many leaves, whoſe lobes are cut outward toward the top.* Leviſticum vulgare. Mor. Hiſt. 3. p. 275. *Common Lovage.*
2. LIGUSTICUM (*Scoticum*) foliis biternatis. Lin. Sp. Plant. 250. *Lovage with double trifoliate leaves* Liguſticum Scoticum Apii folio. Tourn. Inſt. R. H. 324. *Scotch Lovage with a Smallage leaf.*
3. LIGUSTICUM (*Auſtriacum*) foliis bipinnatis, foliolis confluentibus inciſis integerrimis. Lin. Sp. 360. *Lovage with double winged leaves, whoſe lobes run together, and have entire ſegments.* Liguſticum cicutæ folio glabrum. Tourn. Inſt. R. H. 323. *Lovage with a ſmooth Hemlock leaf.*
4. LIGUSTICUM (*Lucidum*) foliis pinnatifidis, foliolis linearibus planis. *Lovage with wing-pointed leaves, whoſe lobes are very narrow and plain.* Liguſticum Pyrenaicum, fœniculi folio lucidum. Tourn. Inſt. 324. *Lovage of the Pyrenees, with a ſhining Fennel leaf.*
5. LIGUSTICUM (*Peloponnaſiacum*) foliis multiplicato-pinnatis, foliolis pinnatim inciſis. Lin. Sp. 36. *Lovage with leaves many times winged, and lobes cut like wings.* Cicutaria latifolia fœtida. C. B. P. 161. *Broad-leaved, ſtinking, Baſtard Hemlock.*

The firſt ſort is the common Lovage of the ſhops; this was formerly cultivated in the kitchen-gardens as an eſculent herb, but has been long diſuſed as ſuch in England. It grows naturally upon the Appenines, and alſo near the river Liguria not far from Genoa; this hath a ſtrong, fleſhy, perennial root, which ſtrikes deep into the ground, and is compoſed of many ſtrong fleſhy fibres covered with a brown ſkin, and has a ſtrong, hot, aromatic ſmell and taſte. The leaves are large, winged, and compoſed of many large lobes ſhaped like thoſe of Smallage, but are larger, and of a deeper green. The lobes toward the top are cut into acute ſegments. The ſtalks riſe to the height of ſix or ſeven feet; they are large and channelled, dividing into ſeveral branches, each being terminated by a large umbel of yellow flowers, which are ſucceeded by oblong ſtriated ſeeds. It flowers in June and July, and the ſeeds ripen in autumn.

This is eaſily propagated by ſeeds, which ſhould be ſown in autumn ſoon after they are ripe; for when they are kept out of the ground till ſpring, they ſeldom grow the firſt year; when the plants come up and are fit to remove, they may be tranſplanted into a moiſt rich border, at about three feet diſtance from each other; and after they have taken new root, they will require no other care but to keep them clean from weeds. The roots will abide many years, and where the ſeeds are permitted to ſcatter, the plants will come up without care.

The roots, leaves, and ſeeds of Lovage, are heating and drying; they warm and comfort the ſtomach, expel wind, and provoke urine.

The ſecond ſort grows naturally near the ſea in many parts of Scotland; this hath a biennial root, but of much leſs ſize than the former; the leaves are compoſed of broader and ſhorter lobes, each leaf having two or three trifoliate leaves, whoſe lobes are indented on their edges. The ſtalk riſes about a foot high, ſuſtaining a ſmall umbel of yellow flowers on the top, ſhaped like thoſe of the former; theſe appear in June, and are ſucceeded by oblong channelled ſeeds, which ripen in autumn. This plant may be cultivated in the ſame manner as the former.

The third ſort grows naturally on the Alps; this is a perennial plant. The ſtalks riſe about two feet high, and at every joint are bent alternately, firſt to one ſide, then to the oppoſite; at every joint they are garniſhed with doubly winged leaves, compoſed of ſmall lobes which run into each other, and juſt above each leaf comes out a ſide branch; theſe, as alſo the principal ſtalks, are terminated by umbels of white flowers, which appear in June, and are ſucceeded by oblong channelled ſeeds, which ripen in autumn.

The fourth ſort grows naturally on the Pyrenean Mountains; this hath a biennial root. The leaves are doubly winged. The lobes are very narrow, and finely divided. The ſtalks are ſtrong, and riſe a foot and a half high, garniſhed with ſhining winged leaves, and are terminated by pretty large umbels of whitiſh flowers, which appear in June, and the ſeeds ripen in September.

The fifth ſort grows naturally on the Peloponeſian Mountains; this hath a very thick fleſhy root like that of Parſnep, which ſtrikes deep in the ground. The leaves are very large, being compoſed of many winged leaves, whoſe lobes are cut into acute points; theſe are of a deep green, and, when bruiſed, emit a fœtid odour. The ſtalks riſe three or four feet high; they are very large and hollow, like thoſe of Hemlock, and ſuſtain at their top large umbels of yellowiſh flowers, in ſhape of a corymbus; theſe appear in June, and are ſucceeded by oblong channelled ſeeds which ripen in autumn.

This has by ſome perſons been thought to be the Hemlock of the antients, their conjectures being founded upon the plant anſwering in many particulars to the deſcription, and alſo from the poiſonous quality of this together with its fœtid ſcent; and as this grows naturally in many parts of Aſia, ſo they have been induced to believe it might be the ſame plant.

All theſe plants are preſerved in botanic gardens for the ſake of variety, but are ſeldom cultivated any where elſe; they riſe eaſily from ſeeds, which ſhould be ſown in autumn, and the plants afterward treated in the ſame way as the firſt; they love a moiſt ſoil and a ſhady ſituation.

LIGUSTRUM. Tourn. Inſt. R. H. 596. tab. 367. Lin. Gen. Plant. 18. Privet; in French, *Troene*.

The Characters are,

The flower has a ſmall tubular empalement, cut at the top into four obtuſe ſegments. It hath one funnel-ſhaped petal, with a cylindrical tube cut into four oval ſegments at the top, which ſpread open. It hath two ſtamina which ſtand oppoſite, terminated by erect ſummits which are the length of the tube of the petal, and one roundiſh germen ſupporting a ſhort ſtyle, crowned by an obtuſe bifid ſtigma. The germen afterward turns to a ſmooth round berry with one cell, incloſing two oblong ſeeds, flat on one ſide, but convex on the other.

This genus of plants is ranged in the firſt ſection of Linnæus's ſecond claſs, which includes thoſe plants whoſe flowers have two ſtamina and one ſtyle.

The Species are,

1. Liguſtrum (*Vulgare*) foliis lanceolato-ovatis obtuſis. *Privet with ſpear-ſhaped, oval, obtuſe leaves.* Liguſtrum Germanicum. C. B. P. 475. *The common Privet.*
2. Liguſtrum (*Italicum*) foliis lanceolatis acutis. *Privet with ſpear-ſhaped leaves.* Liguſtrum foliis majoribus & magis acuminatis toto anno folia retinens. Pluk. Alm. 217. *Privet with larger and more acute-pointed leaves, which continue all the year, commonly called the Italian ever-green Privet.*

The firſt ſort grows common in the hedges in moſt parts of England, where it riſes fifteen or ſixteen feet high, with a woody ſtem, covered with a ſmooth gray bark, ſending out many lateral branches which are garniſhed with ſpear-ſhaped, oval, ſmooth leaves, ending with obtuſe points; they are placed by pairs oppoſite, ſitting cloſe to the branches, and are of a dark green. The flowers are produced in thick ſpikes at the end of the branches; they are white, with one tubular petal cut at the top into four parts, which ſpread open. Theſe come out in June, and are ſucceeded by ſmall round black berries, which ripen in the autumn; each of theſe contain two ſeeds. The leaves of this ſort frequently remain green till after Chriſtmas, when they alter their colour and fall off.

There are two varieties of this ſort, one whoſe leaves are variegated with white, and the other hath leaves variegated with yellow; but in order to preſerve theſe varieties, they ſhould be planted in poor land; for if they are in a rich ſoil, they will grow vigorous and ſoon become plain.

The other ſort grows naturally in Italy; this riſes with a ſtronger ſtalk than the former, the branches are leſs pliable and grow more erect; their bark is of a lighter colour; the leaves are much larger, and end in acute points; they are alſo of a brighter green, and continue upon the ſhrubs in verdure, till they are thruſt off by the young leaves in the ſpring, as the Phillyrea and moſt other Evergreens do; ſo that it is undoubtedly a diſtinct ſort, though many have ſuppoſed they were the ſame. The flowers of this are rather larger than thoſe of the common ſort, and are not often ſucceeded by berries in this country.

The leaves and flowers of the firſt ſort are uſed in medicine; they are reckoned to be cooling, drying, and reſtringent, good for ulcers and inflammations of the mouth and throat, bleeding of the gums, and relaxation of the uvula.

This ſhrub is frequently cultivated in the nurſeries near London, to furniſh the ſmall gardens and balconies in the city, it being one of the few plants which will thrive in the ſmoke of London; but although it will live ſome years in the cloſe part of the town, yet it ſeldom produces flowers there after the firſt year, unleſs it is in ſome open places, where there is a free air. In the country, the leaves of this plant will continue green great part of the winter. It flowers in June, and the berries ripen in autumn, which generally hang upon the branches till Chriſtmas.

The Italian ſort is now generally preferred to the common ſort for planting in gardens, the leaves being larger and continuing green all the year, renders it more valuable; and being ſo hardy as to reſiſt the greateſt cold in this country, it may be planted in any ſituation where the common ſort will thrive. I have frequently planted it under the dropping of large trees, where I find it will thrive better than moſt other ſhrubs.

I cannot but think this ſort which is the moſt common in Italy, is the Liguſtrum mentioned by Virgil in the ſecond Eclogue: and my reaſon for it is, that as the flowers of this ſhrub are of a pure white, but fall off very ſoon, they are by no means proper to gather for garlands, &c. and the berries being of a fine black colour, and continuing long upon the plants, make a fine appearance. To confirm that theſe berries were gathered for uſe, we find in ſeveral authors of undoubted credit, that they were uſed in dyeing, as alſo that the beſt ink was made of theſe berries.

Beſides, is it not much more reaſonable to ſuppoſe, that Virgil would rather draw his compariſon from the flowers and fruit of the ſame plant, when he is warning the youth not to truſt to his beauty, than to mention two different plants, as has been generally ſuppoſed? for here are the white flowers of the Privet appearing early in the ſpring, which is an alluſion to youth; but theſe are of ſhort duration, ſoon falling away; whereas the berries, which may be applied to mature age, are of long continuance, and are gathered for uſe.

Theſe plants are eaſily propagated by laying down their tender ſhoots in autumn, which in one year's time will be rooted enough to tranſplant; when they may be removed to the places where they are deſigned to remain, or planted in a nurſery for two or three years, where they may be trained for the purpoſes deſigned.

They are alſo propagated by ſuckers, which theſe plants ſend forth in great plenty; but theſe are too apt to put out a great number of ſuckers from their roots, ſo are not eaſily kept within bounds; nor do the plants riſe ſo high as thoſe which are propagated by layers, therefore this method ſhould be preferred.

They may alſo be propagated by cuttings, which, if planted in the autumn on a ſhady border and in a loamy ſoil, will take root very freely, and may be afterward treated in the ſame way as the layers.

But the ſtrongeſt and beſt plants, are thoſe which are raiſed from ſeeds; indeed, this is a much more tedious method than the other, ſo is ſeldom practiſed, for the ſeeds generally lie a year in the ground before they vegetate; therefore, whoever would propagate the plants in this method, ſhould gather the berries when ripe, and put them into a pot with ſand between them, and bury the pot in the ground, as is practiſed for Holly berries and Haws; and after they have laid a year in the ground, take them up in the autumn, and ſow them on a border expoſed to the eaſt, where the plants will come up the following ſpring, and theſe will make great progreſs after they have gotten ſome ſtrength, ſo will grow upright, and not ſend out ſuckers like the other.

Formerly theſe plants were greatly in uſe for hedges, but ſince ſo many others of great beauty have been introduced, which are much preferable to theſe for ſuch purpoſes, they have been entirely rejected, the trouble of keeping them in order being very great; nor are the hedges made with them ever ſo thick and handſome, as thoſe made with divers other plants.

The two variegated kinds are pretty varieties amongſt other ſtriped ſhrubs. Theſe may be propagated by budding, or inarching them upon the plain ſort, as alſo by laying down their branches; but as they ſeldom ſhoot ſo faſt, as to produce any branches proper for layers, the other method is chiefly uſed. The ſilver ſtriped ſort is ſomewhat tenderer than the plain, but will endure the open air, if planted in a dry ſoil and in a warm ſituation.

LILAC. See Syringa.

LILIASTRUM. See Hemerocallis.

LILIO-ASPHODELUS. See Hemerocallis and Crinum.

LILIO-FRITILLARIA. See Fritillaria.

LILIO-HYACINTHUS. See Scilla.

LILIO-NARCISSUS. See Amaryllis.

LILIUM. Tourn. Inſt. R. H. 369. tab. 191. Lin. Gen. Plant. 371. [takes its name of λεῖος, ſmooth, poliſhed, becauſe its leaves are, as it were, poliſhed; or of λειρὸν, which ſignifies the ſame thing,] the Lily; in French, *Lis.*

The Characters are,

The flower has no empalement; it hath ſix petals, which are narrow at their baſe, but are broad, obtuſe, and reflexed at their points. The flower is of the open bell-ſhape, the petals are thick, obtuſe, and keel-ſhaped; on their back each petal has a narrow longitudinal nectarium at their baſe. It hath ſix ſtamina which are erect and ſhorter than the petals, terminated by oblong proſtrate ſummits, with a cylindrical oblong germen having ſix furrows, ſupporting a cylindrical ſtyle the length of the petals, crowned by a thick triangular ſtigma. The germen afterward becomes an oblong capſule with ſix rough furrows hollowed at the top, having three cells which are filled with flat half round ſeeds, lying above each other in a double order.

This genus of plants is ranged in the firſt ſection of Linnæus's ſixth claſs, which includes thoſe plants whoſe flowers have ſix ſtamina and one ſtyle.

The Species are,

1. Lilium (*Candidum*) foliis ſparſis, corollis campanulatis erectis, intus glabris. Hort. Cliff. 120. *Lily with ſparſed leaves, and a bell-ſhaped erect flower which is ſmooth within.* Lilium album, flore erecto & vulgare. C. B. P. 76. *Common white Lily with an erect flower.*
2. Lilium (*Peregrinum*) foliis ſparſis, corollis campanulatis cernuis, petalis baſi anguſtioribus. *Lily with ſparſed leaves, and a bell-ſhaped nodding flower, whoſe petals are narrower at their baſe.* Lilium album, floribus dependentibus, ſive peregrinum. C. B. P. 76. *White foreign Lily with pendent flowers.*
3. Lilium (*Bulbiferum*) foliis ſparſis, corollis campanulatis erectis, intus ſcabris. Hort. Cliff. 120. *Lily with ſparſed leaves, and an erect bell-ſhaped flower, rough within.* Lilium purpureo-croceum majus. C. B. P. 76. *Greater Lily with a purple Saffron-coloured flower, commonly called Orange Lily.*
4. Lilium (*Humile*) humile, foliis linearibus ſparſis, corollis campanulatis erectis, caule bulbifero. *Dwarf Lily with narrow ſparſed leaves, erect bell-ſhaped flowers, and a ſtalk bearing bulbs.* Lilium bulbiferum minus. C. B. P. 77. *Smaller bulb-bearing Lily, by ſome called the fiery Lily.*
5. Lilium (*Pomponium*) foliis ſparſis ſubulatis, floribus reflexis, corollis revolutis. Hort. Cliff. 120. *Lily with awl-ſhaped ſparſed leaves and reflexed flowers, whoſe petals are turned backward.* Lilium rubrum anguſtifolium. C. B. P. 78. *Narrow-leaved red Lily or Martagon.*
6. Lilium (*Anguſtifolium*) foliis linearibus ſparſis, pedunculis longiſſimis. *Lily with narrow ſparſed leaves, and very long foot-ſtalks to the flowers.* Lilium brevi & gramineo folio. C. B. P. 79. *Lily with a ſhort Graſs leaf, commonly called Martagon of Pompony.*
7. Lilium (*Chalcedonicum*) foliis ſparſis lanceolatis, floribus reflexis, corollis revolutis. Hort. Cliff. 120. *Lily with ſparſed ſpear-ſhaped leaves, and reflexed flowers whoſe petals turn backward.* Lilium Byzantinum miniatum. C. B. P. 78. *Lily of Byzantium with a carmine flower, commonly called the ſcarlet Martagon.*
8. Lilium (*Superbum*) foliis ſparſis lanceolatis, floribus pyramidatis reflexis, corollis revolutis. *Lily with ſparſed ſpear-ſhaped leaves, and pyramidal reflexed flowers, whoſe petals turn backward.* Martagon multis & magnis floribus luteis alios ſuperans. Suvert. Icon. Pl. 57. *The great yellow Martagon.*
9. Lilium (*Martagon*) foliis verticillatis, floribus reflexis, corollis revolutis. Hort. Cliff. 120. *Lily with leaves growing in whorls, and reflexed flowers whoſe petals turn backward.* Lilium floribus reflexis montanum. C. B. P. 77. *Mountain Lily with reflexed flowers, commonly called purple Martagon.*
10. Lilium (*Hirſutum*) foliis verticillatis hirſutis, floribus reflexis, corollis revolutis. *Lily with hairy leaves growing in whorls, and reflexed flowers whoſe petals turn backward.* Lilium floribus reflexis alterum lanugine hirſutum. C. B. P. 718. *Another Lily with reflexed flowers which is hairy and downy, commonly called the red Martagon.*
11. Lilium (*Canadenſe*) foliis verticillatis, floribus reflexis corollis campanulatis. Lin. Sp. Plant. 303. *Lily with leaves growing in whorls, and reflexed bell-ſhaped flowers.* Lilium, ſc. martagon Canadenſe maculatum. Mor. Hiſt. 2. p. 408. *Lily, or Martagon of Canada with ſpotted flowers.*
12. Lilium (*Campſchatenſe*) foliis verticillatis, floribus erectis, corollis campanulatis. Amœn. Acad. 2. p. 348. *Lily with leaves growing in whorls, and an erect bell-ſhaped flower.*
13. Lilium (*Philadelphicum*) foliis verticillatis brevibus, corollis campanulatis, unguibus petalorum anguſtioribus, floribus erectis. Icon. tab. 165. *Lily with very ſhort leaves growing in whorls, and bell-ſhaped flowers whoſe petals are very narrow at their baſe.*

There is a greater variety of Martagons than are here mentioned, but as they are ſuppoſed to be only accidental ariſing from culture, ſo I thought it would be to little purpoſe to inſert them here; therefore I ſhall only give their common titles hereafter.

The common white Lily is ſo well known as to need no deſcription; this grows naturally in Paleſtine and Syria, but has been long cultivated in all the gardens of Europe. It is ſo hardy that no froſt ever injures the roots in England, and it propagates ſo faſt by offſets from the roots, that it is become ſo common as to be little regarded, though there is great beauty in the flowers, and they emit an agreeable odour. Of this ſort there are the following varieties:

11. The white Lily ſtriped with purple.
The white Lily with variegated leaves.
The white Lily with double flowers.

Theſe are varieties which have accidentally riſen from culture; the ſort with variegated flowers has not been in England much more than thirty-five years, but is now very common in moſt of the gardens, and is by ſome perſons eſteemed for the variety of its purple ſtripes; but as the pure white of the flower is ſtained by the purple, ſo as to appear of a dull colour, therefore many prefer the common white Lily.

The ſort with variegated leaves is chiefly valued for its appearance in winter and ſpring, for as the leaves come up early in the autumn, which ſpread themſelves flat on the ground, and being finely edged with broad yellow ſtripes, they make a pretty appearance during the winter and ſpring months. The flowers are the ſame as thoſe of the common ſort, but appear earlier in ſummer, which may be occaſioned by the roots being weaker than thoſe of the plain ſort, for all variegated plants are weaker than thoſe which are plain.

The white Lily with double flowers is leſs valuable than either of the other, becauſe their flowers never open well, unleſs they are covered with glaſſes to ſhelter them from the rain and dew, ſo often rot without expanding. Theſe flowers have none of the agreeable odour which the ſingle ſort is valued for, even when they open the faireſt; for as by the multiplicity of petals in the flowers, the parts of generation are deſtroyed, ſo there is a want of the fecundating powder from whence the odour is ſent out.

The roots, leaves, and flowers of the common white Lily are uſed in medicine; the roots are frequently uſed to ſoften, ripen, and digeſt tumours and hard ſwellings. Matthiolus ſays, that the diſtilled water of the flowers, is properly and ſucceſsfully given to women in hard labour; and the diſtilled water of the leaves is of great uſe in diſtempers of the lungs.

The white Lily with dependent flowers, was originally brought from Conſtantinople. This is by ſome ſuppoſed to be only a variety of the common ſort, but is undoubtedly a diſtinct ſpecies; the ſtalk is much ſlenderer than the common, the leaves are narrower and fewer in number; the flowers are not quite ſo large, and the petals are more contracted at their baſe; theſe always hang downward, whereas thoſe of the common ſort grow erect. The ſtalks of this kind ſometimes are very broad and flat, and appear as if two or three were joined together; when this happens, they ſuſtain from ſixty to a hundred flowers, and ſometimes more; this has occaſioned many to think it a different ſort, who have mentioned this with broad ſtalks and many flowers as a diſtinct ſpecies, though it is accidental, for the ſame root ſcarce ever produces the ſame two years.

Theſe ſorts are eaſily propagated by offsets, which the roots ſend out in ſo great plenty, as to make it neceſſary to take them off every other, or at moſt every third year, to prevent their weakening the principal roots. The time for removing the roots is at the end of Auguſt, ſoon after the ſtalks decay; for if they are left longer in the ground, they will ſoon put out new fibres and leaves, when it will be improper to remove them, becauſe that will prevent their flowering the following ſummer. They will thrive in almoſt any ſoil or ſituation, and as they grow tall and ſpread, ſo they muſt be allowed room; therefore in ſmall gardens they take up too much ſpace, but in large borders they are very ornamental.

The common Orange or red Lily, is as well known in the Engliſh gardens as the white Lily, and has been as long cultivated here. This grows naturally in Auſtria and ſome parts of Italy. This ſort multiplies very faſt by offsets from the roots, and is now ſo common, as to be almoſt rejected; however, in large gardens theſe ſhould not be wanting, for they make a good appearance when in flower, if they are properly diſpoſed. Of this ſort there are the following varieties;

The Orange Lily with double flowers.
The Orange Lily with variegated leaves.
The ſmaller Orange Lily.

Theſe varieties have been obtained by culture, and are preſerved in the gardens of floriſts. They all flower in June and July, and their ſtalks decay in September, when the roots may be tranſplanted, and their offsets taken off, which ſhould be done once in two or three years, otherwiſe their bunches will be too large, and the flower-ſtalks weak. This doth not put out new leaves till toward ſpring, ſo that the roots may be tranſplanted at any time after the ſtalks decay till near Chriſtmas. It will thrive in any ſoil or ſituation, but will be ſtrongeſt in a ſoft gentle loam not too moiſt.

The bulb-bearing fiery Lily ſeldom riſes much more than half the height of the former; the leaves are narrower, the flowers are ſmaller, and of a brighter flame colour; they are few in number, and ſtand more erect. Theſe come out a month before the common ſort, and the ſtalks put out bulbs at moſt of the joints, which, if taken off, when the ſtalks decay, and planted, will produce plants, ſo that it may be propagated in plenty. There are ſeveral varieties of this, which are mentioned as diſtinct ſpecies, but are ſuppoſed to have been produced by culture. Theſe are,

The greater broad-leaved bulb-bearing Lily.
The many-flowered bulb-bearing Lily.
The ſmall bulb-bearing Lily.
The hairy bulb-bearing Lily.

All theſe ſorts of Lilies will thrive under the ſhade of trees, ſo may be introduced in plantations, and on the borders of woods, where they will have a good effect during the time they are in flower.

There is a great variety of the Martagon Lily; theſe differ from the common Lilies, in having their petals reflexed backward in form of a Turk's turbant, from whence many give them the title of Turk's Cap. In the gardens of the floriſts, particularly thoſe in Holland, they make a great variety of theſe flowers, amounting to the number of thirty or upward; but in the Engliſh gardens, I have not obſerved more than half that number, and moſt of theſe are accidental, for thoſe before enumerated, are all that I think may be ſuppoſed ſpecifically different. However, for the ſake of ſuch as are curious in collecting theſe ſorts of flowers, I ſhall here mention all thoſe varieties which are to be found in the Engliſh gardens.

The common Martagon with double flowers.
The white Martagon.
The double white Martagon.
The white ſpotted Martagon.
The Imperial Martagon.
The early ſcarlet Martagon.
The Conſtantinople Vermillion Martagon.

The common Martagon with red flowers, which is the fifth ſort before enumerated, has very narrow leaves, growing without order. The ſtalk riſes near three feet high, ſuſtaining at the top eight or ten bright red flowers, which ſtand at a diſtance from each other. Theſe appear in June, and the ſtalks decay in Auguſt, ſoon after which time the roots may be tranſplanted.

The ſixth ſort is called Martagon of Pompony; the ſtalks of this riſe higher than thoſe of the former, the leaves are ſhorter, and ſet cloſer upon the ſtalks; each of theſe ſtalks ſuſtain from fifteen to thirty flowers, of a very bright red, approaching to ſcarlet. The foot-ſtalks of the flowers are very long, ſo that the head of flowers ſpreads out very wide; theſe hang downward, but their petals are reflexed quite back. This flowers ſoon after the fifth ſort.

The ſeventh ſort is commonly known by the title of Scarlet Martagon; this riſes with a ſtalk from three to four feet high; the leaves are much broader than thoſe of the former ſorts, and appear as if they were edged with white; they are placed very cloſely upon the ſtalks, but without any order. The flowers are produced at the top of the ſtalk; they are of a bright ſcarlet, and are ſeldom more than five or ſix in number. This flowers late in July, and in cool ſeaſons will continue in beauty great part of Auguſt.

The eighth ſort riſes with a ſtrong ſtalk from four to five feet high, garniſhed with leaves as broad as thoſe of the laſt mentioned, which ſtand without order; the flowers are produced in form of a pyramid, on the upper part of the ſtalk. When the roots of this kind are ſtrong, they produce forty or fifty flowers upon each ſtalk; they are large, of a yellow colour, ſpotted with dark ſpots, ſo make a fine appearance; but the flowers have ſo diſagreeable ſtrong ſcent, that few perſons can endure to be near them, which has occaſioned their being thrown out of moſt Engliſh gardens. This flowers the latter end of June.

The ninth ſort is frequently called the Purple Martagon, though in moſt of the old gardens it is known ſimply by the title of Turk's Cap. This riſes with a ſtrong ſtalk from three to four feet high, garniſhed by pretty broad leaves, which ſtand in whorls round the ſtalk, at certain diſtances. The flowers are of a dark purpliſh colour, with ſome ſpots of black; they are produced in looſe ſpikes on the top of the ſtalks. This flowers in June; the flowers of this ſort have a very diſagreeable odour when near, but it is not ſo offenſive as the former ſort.

The tenth ſort is very like the former, but the leaves are narrower; the whorls ſtand farther aſunder, the leaves and ſtalks are ſomewhat hairy, and the buds of the flowers are covered with a ſoft down: the flowers are of a brighter colour with few ſpots, and come out earlier in the ſummer, though the ſtalks appear much later above ground. This flowers early in June, and the ſtalks decay in Auguſt.

The eleventh ſort is commonly called the Canada Martagon, as it was firſt brought to Europe from thence, but it grows naturally in moſt parts of North America. The roots of this are oblong and large, made up of ſcales like the other ſorts; the ſtalks riſe from four to five feet high, garniſhed with oblong pointed leaves placed in whorls round the ſtalk. The flowers are produced toward the top of the ſtalk; they are large, of a yellow colour, ſpotted with black, which are ſhaped like the flowers of the Orange Lily; the petals of them are not turned backward ſo much as thoſe of the other ſorts of Martagon. This flowers the beginning of Auguſt, and when the roots are large, the ſtalks have a good number of flowers, ſo make a fine appearance. There are two varieties of this, one with larger and deeper coloured flowers than the other, but they are ſuppoſed to have accidentally come from ſeeds.

The twelfth ſort grows naturally in North America, and is alſo mentioned to grow at Campſchatſki. This hath erect flowers ſhaped like thoſe of the Canada Martagon, but the petals of this are oval, not narrowed at their baſe as are thoſe, and ſit cloſe to the foot-ſtalk; the flowers are of a deeper colour, and not ſo much ſpotted as the other ſort. It flowers in July, and the ſtalks decay in the autumn.

This ſort is at preſent rare in England, being in very few gardens. It was ſent me a few years ago from Maryland, but after it had flowered the root periſhed.

The thirteenth ſort was ſent me from Penſylvania by Mr. John Bartram, who found it growing naturally in that country. The root of this is ſmaller than thoſe of the other ſorts; it is ſcaly and white; in the ſpring it ſends out one upright ſtalk near a foot and a half high; the leaves come out in whorls round the ſtalks, at diſtances; they are ſhort, pretty broad, and have obtuſe points. The ſtalk is terminated by two flowers which ſtand erect, upon ſhort ſeparate foot-ſtalks; they are ſhaped like the flowers of the bulb-bearing fiery Lily, but the petals are narrower at their baſe, ſo that there are ſpaces between each, but upward they enlarge and join, forming a ſort of open bell-ſhaped flower; their petals are ſpear-ſhaped, ſo are contracted at the top, where they terminate in acute points. The flowers are of a bright purple colour, marked with ſeveral dark purple ſpots toward their baſe. In the center of the flower is ſituated a ſix-cornered germen, ſupporting a ſtrong ſtyle, crowned by a three-cornered ſtigma; round this are ſituated ſix awl-ſhaped ſtamina, terminated by oblong proſtrate ſummits; theſe are a little ſhorter than the ſtyle. The germen afterward turns to an oblong capſule with three angles, blunt at the top, divided into three cells, filled with flat ſeeds lying over each other. It flowers in July, and the ſeeds ripen the latter end of September.

This ſort is at preſent very rare in the Engliſh gardens, but as it has ripened ſeeds the laſt ſeaſon here, ſo it may in a few years become very common. As this ſort grows in a ſmall compaſs, and the flowers have no ill ſcent, it is proper furniture for the borders of ſmall gardens. The ſtalks of this decay ſoon after the ſeeds are ripe, when it will be a proper time to remove the roots, for theſe do not put out new fibres till after Chriſtmas. The roots of this kind do not put out many offſets, ſo that unleſs it is propagated by ſeeds, it cannot be increaſed in any plenty.

All the ſorts of Martagon may be propagated by offſets from the roots, in the ſame way as the common Lily, which ſome of the ſorts produce in as great plenty; but there are others which ſend out very few offſets, which occaſion their preſent ſcarcity. The roots of all the ſorts of Martagon may be ſafely taken up when their ſtalks decay; and if there is a neceſſity for keeping the roots out of the ground, if they are wrapped in dry Moſs, they will keep perfectly well for two months; ſo that if the roots are to be tranſported to a diſtant place, this precaution of wrapping them up is neceſſary; but where they are to be planted in the ſame garden, there will be no occaſion for this, eſpecially if they are not kept too long out of the ground; for if the place is ready to receive the roots, they ſhould be planted the beginning of October; ſo if the roots are put in a dry cool place, they will keep very good without any further care; but if the ground is not ready to receive them till later in the year, then it will be proper to cover the roots with dry ſand, or wrap them in Moſs to exclude the air, which, if they are much expoſed to, will cauſe their ſcales to ſhrink, which weakens the roots, often cauſing a mouldineſs, and is ſometimes the occaſion of their rotting.

Theſe roots ſhould be planted five or ſix inches deep in the ground, eſpecially if the ſoil is light and dry; but where the ground is moiſt, it will be proper to raiſe the borders in which theſe are to be planted, five or ſix inches above the level of the ſurface of the ground; for if the water riſes ſo high in winter as to come near the roots, it will cauſe them to rot; and where the ſoil is naturally ſtiff and ſubject to bind, there ſhould be a good quantity of ſea-coal aſhes or rough ſand, well mixed in the border, to ſeparate the parts, and prevent the ground from binding in the ſpring, otherwiſe the roots will not ſend up very ſtrong ſtalks, nor will they make ſo good increaſe.

As the Canada Martagon, the Martagon of Pompony, and the laſt ſort, are ſomewhat tenderer than the others, ſo if in very ſevere winters the ſurface of the ground over them is covered with old tanners bark or ſea-coal aſhes, it will be a good way to ſecure them from being injured by the froſt; and in the ſpring the covering may be removed, before the roots ſhoot up their ſtalks.

The tall growing ſorts of theſe are only proper for large gardens, ſo they may be intermixed with the white and Orange Lilies, the tall growing Iriſes, and other flowers of the ſame growth; where, if they are not too much crowded, and are properly diſpoſed, they will make a good appearance; and as they flower one after another, ſo they may be diſpoſed according to their ſeaſons of flowering. There are ſome of the common Martagons hardy enough to thrive under the ſhade of trees, ſo they may be diſpoſed in wilderneſs quarters, with the common ſort of Lilies, where they will have a good effect.

The roots of all theſe kinds muſt never be tranſplanted after they have made any ſhoots, for that will ſo much weaken them (if it does not entirely kill them) as not to be recovered in leſs than two or three years, as I have experienced to my coſt; for being obliged to remove a fine collection of theſe roots early in the ſpring, I loſt a great part of them, and the others were long recovering their ſtrength.

All the ſorts of Lilies and Martagons may be propagated by ſowing their ſeeds, by which method ſome new varieties may be obtained, provided the ſeeds are ſaved from the beſt ſorts; eſpecially the Martagons, which are more inclinable to vary than the other Lilies. The manner of ſowing them is as follows:

You muſt be provided with ſome ſquare boxes about ſix inches deep, which ſhould have holes bored in their bottoms to let the wet paſs off: theſe boxes ſhould be filled with freſh light ſandy earth, and in the beginning of October, ſoon after the ſeeds are ripe, you muſt ſow them thereon pretty thick, covering them over with light ſifted earth about half an inch; then place the boxes where they may have the morning ſun only, obſerving if the ſeaſon ſhould prove dry, to refreſh them often with water, as alſo to pull out all weeds which may be produced. In this ſituation the boxes ſhould remain until the beginning of November, when you muſt remove them where they may have as much ſun as poſſible, as alſo be ſcreened from the cold north and eaſt winds during the winter ſeaſon; but in the ſpring of the year, about the beginning of April, you muſt remove the boxes into their former poſition; for now the young plants will appear above ground, which are impatient of too much heat; beſides, the earth in the boxes will dry too faſt at this ſeaſon, if expoſed to the full ſun at noon. You muſt alſo obſerve at this ſeaſon to keep them entirely clear from weeds, as alſo to refreſh them gently with water, if the ſeaſon ſhould prove dry, but this muſt be done ſparingly and with caution. In this place you ſhould let the boxes remain until the beginning of Auguſt; at which time you ſhould prepare ſome beds of the above mentioned freſh light earth, which muſt be levelled very even; then take the earth out of the boxes, together with the ſmall bulbs, and ſtrew it equally over the beds, covering it over about half an inch thick with fine ſifted earth; and if the ſeaſon ſhould prove very hot and dry, you would do well to ſhade the beds in the middle of the day from the great heat of the ſun, and refreſh them now and then with water.

You muſt alſo obſerve to keep them entirely clear from weeds, and if the following winter ſhould prove very cold, you muſt cover the beds with Peas-haulm, or ſome other light covering, to keep out the froſt, which would prejudice the roots, if ſuffered to enter deep into the ground (eſpecially while they are ſo young:) but you muſt never let the covering remain on in mild weather, which would alſo be very injurious to them.

The end of February, or the beginning of March, when the hard froſts are over, you ſhould gently clear off the earth upon the ſurface of the beds (which, during the winter ſeaſon, will often have contracted a moſſineſs;) and ſift a little freſh earth equally over the beds, which will greatly encourage the roots; but in doing this, you muſt be very careful not to ſtir the ground ſo deep as to diſturb or injure the roots; nor ſhould you defer doing it too late, leſt the ſhoots ſhould be coming up, which, by this operation might be broken and greatly hurt; and as the ſeaſon advances, you muſt be careful to clear them from weeds, and in dry weather to water them gently, but they ſhould not have it in great plenty; and in very hot days, if you ſhade them from the ſun, it will be of great ſervice to them; but this need not be done till the latter end of April or the beginning of May, when the ſeaſon is ſometimes very hot and dry.

When their leaves are quite decayed, you ſhould ſtir the ſurface of the beds again (but do not go too deep) which will prevent the weeds from growing very faſt, and be of ſervice to the roots; and in September you muſt ſift ſome more freſh earth over the beds about half an inch thick, and in winter and ſpring you muſt manage them as was directed for the preceding year.

In September following theſe roots will require to be tranſplanted to a greater diſtance, when you muſt prepare ſome beds of the ſame freſh light earth as was before directed, making them level; then take up the roots and tranſplant them into the beds, placing them about eight inches aſunder, obſerving to put the roots with their buds uppermoſt, and about four inches below the ſurface.

This work ſhould be done when the weather is moiſt, for if the roots are tranſplanted in a very dry ſeaſon, and there doth not happen rain ſoon after, they will take a mouldineſs which many times rots them.

You muſt alſo obſerve, as was before directed, to keep the beds entirely clear from weeds; and in winter, if the froſt ſhould be very ſevere, you muſt cover them with Peas-haulm or decayed tan, to prevent the roots from being injured thereby; and in the ſpring you ſhould take off the covering, alſo the earth from the ſurface of the beds, as before, laying ſome freſh thereon, and ſo continue the ſummer and winter's work, as before.

The ſecond year after being planted in theſe beds, the ſtrongeſt roots will begin to flower; at which time, if you obſerve any peculiar varieties, you ſhould put down a ſtick by each of theſe roots to mark them; which may be taken up when their leaves are decayed, and removed into the borders of the flower-garden, or tranſplanted into other beds at a greater diſtance, to encourage them to flower ſtrong. But you cannot be ſo good a judge which of thoſe will be good by their firſt flowers, therefore you ſhould never reject any of them until they have flowered two years; for many times, ſome of theſe flowers will make but a mean appearance the firſt year, and afterwards become fair handſome flowers when they have obtained ſtrength; ſo that you ſhould ſuffer all ſuch, of whoſe worth you are not aſſured, to remain undiſturbed two years, that you may be aſcertained which of them are worth preſerving; theſe ſhould be removed into the flower-garden at a proper ſeaſon, but the ordinary ones may be rejected, or planted in ſhady outer walks, where, though they are mean flowers, they will appear well enough.

LILIUM CONVALLIUM. See CONVALLARIA.

LILIUM PERSICUM. See FRITILLARIA.

LILIUM SUPERBUM. See GLORIOSA.

LIME-TREE. See TILIA.

LIMODORUM. Flor. Virg. 110. Lin. Gen. Plant. 904. Helleborine. Tourn. Inſt. R. H. 436. tab. 249. Baſtard Hellebore.

The CHARACTERS are,

It hath a ſingle naked flower-ſtalk, ariſing immediately from the root. The flowers have no empalement, but a ſpatha (or ſheath) ſituated below them. The flower is compoſed of five oval petals, which are diſſimilar. The ſide petals ſpread open, but the two upper are connected together; the lower one is keel-ſhaped, ſo that it has much the appearance of a butterfly flower. Within the petals is ſituated a concave nectarium of one leaf, which is as long as the petals. It has two ſtamina, which are as long as the petals, terminated by two oval ſummits. It hath a column-ſhaped germen ſituated under the flower, which is as long as the petals, ſupporting a ſlender ſtyle, faſtened to the ſtamina, crowned by a funnel-ſhaped ſtigma. The column-ſhaped germen afterward turns to a capſule of the ſame form, opening with three valves, having one cell, in which are lodged four or five roundiſh ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's twentieth claſs, which includes thoſe plants whoſe flowers have but two ſtamina, which are connected with the ſtyle.

We have but one SPECIES of this genus at preſent in England, viz.

LIMODORUM (*Tuberoſum*) foliis longis anguſtis ſulcatis & acuminatis, pedunculis longiſſimis. *Limodorum with long narrow leaves ending in acute points, and a very long foot-ſtalk to the flower.* Helleborine Americana, radice tuberoſâ, foliis longis anguſtis, caule nudo, floribus ex rubro pallidè-purpuraſcentibus. Martyn. Cent. 1. Pl. 50. Icon. tab. 165. *American Baſtard Hellebore with a tuberoſe root, long narrow leaves, a naked ſtalk, and flowers of a red and pale purpliſh colour.*

This plant grows naturally in Jamaica, eſpecially on the north ſide of that iſland, from whence many of the roots were ſent me by the late Dr. Houſtoun, with the following title, Helleborine purpurea, tuberoſâ radice. Plum. Cat. 9. ſo that it is the ſame plant with Plumier's. It alſo grows naturally in the French Iſlands of America. The roots of this were afterward brought me from the Bahama Iſlands, where it was found growing naturally; and it was ſince ſent me from Penſylvania, by Mr. John Bartram, who found it growing naturally in that country.

The root of this plant is ſhaped like that of the true Saffron Crocus, but the outer cover is of a darker brown colour; from this comes out two or three leaves, according to the ſize and ſtrength of the root; theſe are nine or ten inches long, and near three quarters of an inch broad in the middle, being contracted toward both ends, terminating with long acute points, folding over each other at their baſe; they have five longitudinal furrows, like the firſt leaves of young Palms; theſe leaves come out in the ſpring, and frequently decay the following winter; but when the plants are kept in a warm ſtove, they are not very long deſtitute of leaves. The flower-ſtalk ariſes immediately from the root, on one ſide of the leaves; this is naked, ſmooth, and of a purpliſh colour toward the top. It is near a foot and a half high, and terminated by a looſe ſpike of purpliſh red flowers, ſtanding upon ſhort foot-ſtalks; they are compoſed of five or ſix petals, the two upper are connected together, forming a ſort of helmet, the two ſide petals expand like the wings of a butterfly flower, and the lower forms a ſort of keel. In the center of the petals is ſituated a column-ſhaped germen, which riſes from the baſe of the petals, ſupporting a ſlender ſtyle, to which adhere two ſtamina, terminated by oval ſummits, as the ſtyle is by a funnel-ſhaped ſtigma; after the flowers are faded, the germen becomes a three-cornered column-ſhaped capſule, with one cell, opening with three valves, containing ſeveral roundiſh ſeeds, but theſe ſeeds are rarely produced in England.

This plant is not conſtant to any particular ſeaſon of flowering; for ſometimes it has flowered in April and May, and in other years it has not flowered till September or October; but the moſt uſual time of its flowering is in June and July, when the flowers appear early in the ſpring; they are ſucceeded by ſeed-veſſels, which ſometimes ripen in this country.

There are ſeveral other ſpecies of this genus mentioned by Father Plumier, but I have only ſeen one more than this here mentioned, which had oval obtuſe leaves, furrowed in the ſame manner as the leaves of this ſort, but were of a thicker conſiſtence; the flowers of this I have not yet ſeen. The root was ſent me from Maryland, where it grew naturally in a thicket.

The ſort here deſcribed is too tender to thrive in the open air in England, and although with care it may be preſerved in a warm green-houſe, yet it ſeldom flowers in ſuch a ſituation; ſo that to have it in perfection, it is neceſſary to keep it in the tan-bed in the ſtove in winter; and if in ſummer the pots are plunged in a tan-bed under a deep frame, the plants will thrive, and flower as ſtrong as in their native ſoil.

It is propagated by offſets from the root, which are ſent out pretty freely when the plants are in vigour; theſe ſhould be taken off, and the roots tranſplanted when they are the moſt deſtitute of leaves. The roots ſhould have a ſoft loamy ſoil, and muſt have but little water, eſpecially in winter.

LIMODORUM. See Orchis.

LIMON. Tourn. Inſt. R. H. 621. Citrus. Lin. Gen. Plant. 807. [ſo called of Λειμῶν, a meadow, becauſe the leaves of this tree are of a green colour, as is likewiſe the fruit before it comes to maturity.] The Lemon-tree; in French, *Limonier*.

The Characters are,

The flower is compoſed of five oblong thick petals, which are a little concave, ſpreading open; theſe ſit in a ſmall empalement of one leaf, indented at five parts at the top. It hath about ten or twelve ſtamina, which are joined in three or four bodies, which are terminated by oblong ſummits. It hath an oval germen, ſupporting a cylindrical ſtyle the length of the ſtamina, crowned by a globular ſummit. The germen afterward becomes an oval fruit with a fleſhy rind, incloſing a thin pulpy fruit with ſeveral cells, each having two hard ſeeds.

This genus of plants is ranged in the ſixth ſection of Tournefort's twenty-firſt claſs, which includes the trees and ſhrubs with a Roſe-ſhaped flower, whoſe pointal becomes a fleſhy fruit with hard dry ſeeds. Dr. Linnæus has joined the Citron, Orange, and Lemon together, making them only different ſpecies of the ſame genus; but if we admit of the fruit being a characteriſtic note to diſtinguiſh the genus, the Limon cannot be joined with the Orange, for the Orange has a globular fruit, compreſſed at both ends, but the Limon has an oval fruit, prominent at the top, and the latter hath not ſo many cells as the former. It is placed in the ſecond ſection of Linnæus's eighteenth claſs, which includes the plants whoſe flowers have about twenty ſtamina joined in ſeveral bodies.

The Species are,

1. Limon (*Vulgaris*) foliis ovato-lanceolatis acuminatis, ſubſerratis. *Limon-tree with oval, ſpear-ſhaped, acute-pointed leaves, which are little ſawed.* Limon vulgaris. Ferr. Heſp. 193. *The common Limon.*
2. Limon (*Spinoſum*) foliis ovatis integris, ramis ſubſpinoſis. *Limon with oval entire leaves, and branches which are ſomewhat ſpiny.* Limon acris. Ferr. Heſp. 331. *The ſour Limon, commonly called Lime.*
3. Limon (*Racemoſum*) foliis ovato-lanceolatis ſubſerratis, fructu conglomerato. *Limon with oval ſpear-ſhaped leaves, which are ſomewhat ſawed, and fruit growing in cluſters.* Limon fructu racemoſo. Tourn. Inſt. R. H. 621. *Limon with fruit growing in bunches.*

There are great varieties of this fruit, which are preſerved in ſome of the Italian gardens, and in both the Indies there are ſeveral which have not yet been introduced to the European gardens; but theſe, like Apples and Pears, may be multiplied without end from ſeeds, therefore I ſhall only mention the moſt remarkable varieties which are to be found in the Engliſh gardens at preſent, as it would be to little purpoſe to enumerate all thoſe which are mentioned in the foreign catalogues.

The Limon-tree with variegated leaves.
The ſweet Limon.
The Pear-ſhaped Limon.
The imperial Limon.
The Limon called Adam's Apple.
The furrowed Limon.
The childing Limon.
The Limon with double flowers.

The common Limon and the ſweet Limon are brought to England from Spain and Portugal in great plenty, but the fruit of the latter are not much eſteemed. The Lime is not often brought to England, nor is that fruit much cultivated in Europe, but in the Weſt-Indies it is preferred to the Limon, the juice being reckoned wholeſomer, and the acid is more agreeable to the palate; there are ſeveral varieties of this fruit in the Weſt-Indies, ſome of which have a ſweet juice, but thoſe are not greatly eſteemed; and as the inhabitants of thoſe iſlands do not propagate theſe fruits by grafting or budding, being contented with ſowing their ſeeds, ſo there is no doubt but a great variety of them may be found by any perſon who is curious in diſtinguiſhing them.

As I have never known the common Limon ever vary to the Lime, when raiſed from ſeeds, nor the Lime vary to the Limon, I ſuppoſe they are ſpecifically different, for I have frequently raiſed both from ſeeds, and have always found them continue their difference in leaf and branch, for I never waited to ſee their fruit, as they were only deſigned for ſtocks, to bud other ſorts into them.

The Pear-ſhaped Limon is a ſmall fruit with very little juice, ſo is not much propagated any where; the curious, who have room and convenience for keeping many of theſe trees, may preſerve a plant or two of this ſort for the ſake of variety.

The fruit of the Imperial Limon is ſometimes brought to England from Italy, but I do not remember to have ſeen any of this ſort imported from Spain or Portugal, ſo that I ſuppoſe they are not much propagated in either of theſe countries; for the inhabitants of both thoſe fine countries are ſo very incurious, eſpecially in horticulture, as to truſt almoſt entirely to nature, that the products of their gardens are inferior both in numbers and quality, to many other parts of Europe, where the climate is much leſs favourable for theſe productions. And in the article we are now upon, there are many ſtrong inſtances of the ſlothfulneſs, or incurioſity of the Portugueze particularly, for they had many of the moſt curious ſorts of Orange, Limon, and Citron-trees, brought from the Indies to Portugal formerly, which ſeemed to thrive almoſt as well there, as in their native ſoil, and yet they have not been propagated; there are a few trees of theſe ſorts ſtill remaining in ſome neglected gardens near Liſbon, almoſt unnoticed by the inhabitants. As there are alſo ſeveral curious trees and plants, which were formerly introduced from both Indies, ſome of which thrive and produce fruit amidſt the wild buſhes and weeds, with which thoſe gardens are ſpread over.

All theſe ſorts are propagated by budding or inarching them either on ſtocks of Lemons or Citrons, produced from ſeeds, but they will not ſo readily unite on Orange ſtocks, for which reaſon the Citrons are preferable to either Oranges or Lemons for ſtocks, as they readily join with either ſort, and being of larger growth, cauſe the buds of the other ſorts to ſhoot much ſtronger than if they were on ſtocks of their own kind. The method of raiſing theſe ſtocks, and the manner of budding them, being already exhibited under the article of AURANTIUM, it would be ſuperfluous to repeat it here.

The culture of the Lemon being the ſame with that of the Orange-tree, it would be needleſs to repeat it here; therefore I ſhall only obſerve, that the common Lemons are ſomewhat hardier than the Oranges, and will bring their fruit to maturity with us better than they will do, and require to have a greater ſhare of freſh air in winter; for which reaſon, they ſhould always be placed nearer to the doors or windows of the green-houſe; and in ſome curious gardens, theſe trees have been planted againſt walls, where, by covering them with glaſſes in winter, and protecting them from ſevere froſt, they have produced plenty of large fruit: as theſe trees do generally produce ſtronger ſhoots, they require more water to be given them than the Orange; but as to the tender ſorts, they muſt be treated with a little more care, otherwiſe their fruit will fall in winter, and come to nothing; theſe things being fully exhibited before, I refer the reader (as I hinted) to the article AURANTIUM, where their culture is fully ſet forth.

LIMONIUM. Tourn. Inſt. R. H. 341. tab. 177. Statice. Lin. Gen. Plant. 348. [takes its name of Λειμὼν, a marſh, as growing in marſhes.] Sea Lavender.

The CHARACTERS are,

The flowers have an imbricated perianthium, riſing one above another. The flower is funnel-ſhaped, compoſed of five petals, which are narrow at their baſe, but are broad and ſpreading at the top. It hath five awl-ſhaped ſtamina which are ſhorter than the petals, crowned by proſtrate ſummits. It hath a ſmall germen, ſupporting five ſlender ſtyles, crowned by pointed ſtigmas. The empalement of the flower afterward becomes a capſule, ſhut cloſe at the neck, but expanded above where the ſeeds are lodged.

This genus of plants is ranged in the ſecond ſection of Tournefort's eighth claſs, which includes the herbs with a Clove Gilliflower flower, whoſe pointal becomes the ſeed incloſed in the empalement. Dr. Linnæus has joined this genus to the Statice of Tournefort, and places it in the fifth ſection of his fifth claſs, which contains the plants whoſe flowers have five ſtamina and five ſtyles. As the flowers of this genus are ranged one above another in form of ſpikes, and thoſe of the Statice are collected in globuar heads, they may, without impropriety, be kept ſeparate; and as there are ſeveral ſpecies of each genus, therefore I have the rather been inclined ſo to do, than by joining them, to ſwell the genus.

The SPECIES are,

1. LIMONIUM (*Vulgare*) foliis ovato-lanceolatis, caule tereti nudo paniculato. *Sea Lavender with oval ſpear-ſhaped leaves, and a taper paniculated ſtalk.* Limonium maritimum majus. C. B. P. 192. *Common great Sea Lavender.*
2. LIMONINM (*Narbonenſe*) foliis oblongo-ovatis, caule paniculato patulo, ſpicis florum brevioribus. *Sea Lavender with oblong oval leaves, a ſpreading paniculated ſtalk, and ſhorter ſpikes of flowers.* Limonium maritimum majus alterum ſerotinum Narbonenſe. H. R. Par. *Another large late flowering Sea Lavender of Narbonne.*
3. LIMONIUM (*oleæfolium*) foliis ovatis obtuſis, petiolis decurrentibus, caule paniculato, ſpicis florum erectioribus. *Sea Lavender with oval obtuſe leaves, running foot-ſtalks, a paniculated ſtalk, and more upright ſpikes of flowers.* Limonium maritimum minus, oleæ folio. C. B. P. 192. *Small Sea Lavender, with an Olive leaf.*
4. LIMONIUM (*Humile*) foliis lanceolatis, caule humile patulo, ſpicis florum tenuioribus. *Sea Lavender with ſpear-ſhaped leaves, a low ſpreading ſtalk, and ſlender ſpikes of flowers.* Limonium Anglicum minus, caulibus ramoſioribus, floribus in ſpicis rariùs ſitis. Raii Hiſt. 217. *Leſſer Engliſh Sea Lavender, with more branched ſtalks, and flowers ſeldom growing in a ſpike.*
5. LIMONIUM (*Tartaricum*) foliis lineari-lanceolatis, caule ramoſo patulo, floribus diſtantibus uno verſu diſpoſitis. *Sea Lavender with narrow ſpear-ſhaped leaves, a branching ſpreading ſtalk, and flowers placed aſunder on one ſide the ſtalk.* Limonium Orientale, plantaginis folio, floribus umbellatis. T. Cor. *Oriental Sea Lavender with Plantain leaves, and flowers growing in an umbel.*
6. LIMONIUM (*Sinuatum*) foliis radicalibus alternatim pinnato-ſinuatis, caulinis ternis triquetris ſubulatis decurrentibus. *Sea Lavender with the lower leaves alternately ſinuated like wings, and thoſe upon the ſtalks three-cornered, awl-ſhaped, and running along the foot-ſtalk.* Limonium peregrinum, foliis aſplenii. C. B. P. *Foreign Sea Lavender with Spleenwort leaves.*
7. LIMONIUM (*Siculum*) caule fruticoſo patulo, foliis lineari lanceolatis craſſis, floribus ſolitariis diſtantibus. *Sea Lavender with a ſpreading ſhrubby ſtalk, narrow, thick, ſpear-ſhaped leaves, and flowers growing ſingly at a diſtance from each other.* Limonium Siculum lignoſum, gallas ferens, & non ferens. Bocc. Rar. *Woody Sicilian Sea Lavender, ſometimes producing galls, at other times not.*
8. LIMONIUM (*Africanum*) foliis inferioribus lanceolatis hirſutis ſerratis caulinis ternis linearibus acutis decurrentibus. *Sea Lavender with ſpear-ſhaped lower leaves which are hairy and ſawed, but growing by threes on the ſtalks, narrow, acute-pointed, and running along the ſtalk.* Limonium Africanum caule alato, foliis integris hirſutis, petalo pallidè flavo calyce amœnè purpureo. Martyn. Cent. 48. tab. 48. *African Sea Lavender with a winged ſtalk, entire hairy leaves, pale yellow petals to the flower, and a beautiful purple empalement.*
9. LIMONIUM (*Reticulatum*) foliis cuneiformibus, caule erecto paniculato, ramis inferioribus ſterilibus nudis. *Sea Lavender with wedge-ſhaped leaves, an upright paniculated ſtalk, and the under branches ſterile and naked.* Limonium minus flagellis tortuoſis. Bocc. Muſ. *Small Sea Lavender with twiſted ſhoots.*
10. LIMONIUM (*Cordatum*) caule nudo paniculato, foliis ſpathulatis retuſis. *Sea Lavender with a paniculated naked ſtalk, and ſpatule-ſhaped blunt leaves.* Limonium maritimum minus, foliolis cordatis. C. B. P. *Small Sea Lavender with little leaves, which are heart-ſhaped.*
11. LIMONIUM (*Echoideum*) caule nudo paniculato, tereti, foliis tuberculatis. *Sea Lavender with a naked, taper, paniculated ſtalk, and leaves ſet with tubercles.* Limonium minus annuum, bullatis foliis vel echioides. Bot. Monſp. *Small annual Sea Lavender with ſtudded leaves.*
12. LIMONIUM (*Fruticoſum*) caule erecto fruticoſo, foliis lineari-lanceolatis obtuſis, floribus alternis. *Sea Lavender with an upright ſhrubby ſtalk, narrow ſpear-ſhaped leaves, ending in obtuſe points, and flowers ranged alternately.* Limonium Egyptiacum fruticoſum, foliis lanceolatis obtuſis. *Shrubby Egyptian Sea Lavender with blunt ſpear-ſhaped leaves.*

The firſt ſort grows naturally in the marſhes which are flowed by the ſea, in ſeveral parts of England. The roots of this plant are thick, of a reddiſh colour, and an aſtringent taſte, ſending out many ſtrong fibres, which ſtrike deep in the ground; and from the upper part of the root comes out ſeveral oval ſpear-ſhaped leaves, from four to five inches long, and more than two inches broad in the middle; they are ſmooth, of a pretty thick conſiſtence, and of a dark green. The ſtalks riſe upward of a foot high, is naked of leaves, divided into many branches, which are again divided into ſmaller toward the top; theſe are terminated by ſlender ſpikes of pale blue flowers, ranged on one ſide the ſtalk above each other, coming out of narrow covers like ſheaths; theſe appear in July, and are ſucceeded by oblong ſeeds, which are incloſed in the empalement, ripening in autumn.

The ſecond ſort grows naturally in the ſouth of France on the ſea-coaſt. The leaves of this ſort are of an oblong oval form; they are ſix inches long, and three broad, ſmooth, entire, and of a deep green. The ſtalk riſes fifteen or ſixteen inches high, dividing into ſeveral ſpreading branches, which are divided again into ſmaller, and are terminated by ſeveral ſhort ſpikes of pale blue flowers, ranged on one ſide the foot-ſtalk. This ſort ſeldom flowers till the end of Auguſt, ſo never produces any good ſeeds in England.

The third ſort grows naturally in Narbonne and Provence; this hath ſmall, oval, obtuſe leaves, about two inches long, and one broad, with pretty long foot-ſtalks, which are bordered, or winged with part of the leaves, which runs cloſe to, and partly embrace the upper part of the root; theſe are of a lighter green than either of the former. The ſtalk riſes a foot and a half high, ſending out branches alternately on each ſide; the lower ones being long, the others gradually diminiſhing to the top, ſo as to form a looſe kind of pyramid: theſe all point upward, and toward their ends ſend out ſpikes of pale blue flowers, which are erect. This ſort flowers late in Auguſt, ſo never perfects ſeeds in England.

The fourth ſort grows naturally in England. It was firſt diſcovered on the ſea banks near Walton, in Eſſex, afterward near Malden, in the ſame county, and ſince at the mouth of the river that runs from Chicheſter, in Suſſex. The leaves of this ſort are ſpear-ſhaped, about three inches long, and one broad in the middle, leſſening gradually to both ends. The ſtalk riſes four or five inches high, dividing into many ſpreading branches, which are very thick ſet with ſhort ſpikes of whitiſh blue flowers. Theſe appear in Auguſt, and the ſeeds ripen in October.

The fifth ſort was diſcovered by Dr. Tournefort in the Levant, from whence he ſent the ſeeds to the Royal Garden at Paris, where they grew, and have produced ſeeds many years, which have been communicated to many of the curious gardens in Europe. The ſeeds of this ſort were ſent me from the Dardanelles, where the plants grow in plenty. The leaves of this ſort are about four inches long, and three quarters of an inch broad in the middle, diminiſhing gradually to both ends. The ſtalks riſe about five or ſix inches high, dividing into ſeveral ſpreading branches, which are again divided into ſmaller; theſe are terminated by ſpikes of pale blue flowers, ranged on one ſide the foot-ſtalk; the whole, when growing, being ſpread wide, has ſomewhat the appearance of an umbel of flowers. This ſort flowers in Auguſt, ſo never ripens ſeeds here.

The ſixth ſort grows naturally in Sicily and Paleſtine; this is a biennial plant. The lower leaves which ſpread on the ground, are indented almoſt to the middle rib; theſe indentures are alternate and blunt. The ſtalks riſe a foot and a half high, dividing upward into ſeveral branches, garniſhed at each joint with three narrow leaves ſitting cloſe to the ſtalks, from whoſe baſe proceeds a leafy membrane, or wing, which runs along on both ſides the ſtalk; theſe are rough, and a little hairy. The ſtalks are terminated by panicles of flowers, which ſit upon winged foot-ſtalks, each ſuſtaining three or four flowers of a light blue colour, which continue long without fading. This ſort flowers in July and Auguſt, but unleſs the ſummer is very warm and dry, the ſeeds do not ripen in England.

The ſeventh ſort grows naturally in Sicily; this hath a ſhrubby ſtalk, which riſes about two feet high, dividing into ſeveral ligneous branches, which ſpread out on every ſide; the lower part of theſe are cloſely garniſhed with gray leaves, like thoſe of the Sea Purſlain, and are of a thick conſiſtence. The branches are terminated by panicles of blue flowers, having one funnel-ſhaped petal, which come out ſingly at a diſtance from each other, having long tubes, but divide into five ſegments upward, which ſpread open. This flowers from June till autumn, but never produces ſeeds in England: there is a variety of this, which bears galls like thoſe upon the Oak, which grows naturally in Sicily, but I do not know if it is a different ſpecies, for thoſe plants which are in the Engliſh gardens have no appearance of any.

The eighth ſort was raiſed in the Chelſea garden, from ſeeds which were brought me from Africa; this is a biennial plant, which dies ſoon after it has produced flowers and ſeeds. The lower leaves are but few in number; they are ſpear-ſhaped, hairy, and ſlightly ſawed on their edges, about two inches long, and half an inch broad. The ſtalk riſes about fifteen inches high, which at each joint is garniſhed with three narrow leaves, ending in acute points; from the baſe of theſe leaves is continued a leafy membrane, or wing, running along the ſtalk on each ſide; theſe ſtalks branch out but little, and are terminated by ſhort panicles of flowers, whoſe foot-ſtalks are not winged as in the former; each foot-ſtalk ſuſtains two or three flowers of a bright blue colour, out of the middle of which ariſes another ſmall flower of a pale yellow colour. This ſort flowered in July and Auguſt, 1757, but did not ripen ſeeds.

The ninth ſort grows naturally in Sicily, and was found growing on the border of the ſea in Norfolk, by Mr. Henry Scott, a gardener, and has ſince been found in plenty in Lincolnſhire, by —— Banks, Eſq; The lower leaves of this ſort are narrow at their baſe, but enlarge upward, where they are broad, and rounded at the top, in ſhape of a wedge. The ſtalks are ſlender and ſtiff, riſing from ſeven to fourteen inches high, ſending out many ſlender ſide branches; all thoſe which proceed from the lower part of the ſtalk are barren, having no flowers; but toward the top they have ſhort panicles of whitiſh flowers, which are ſmall, and ſit three or four together upon one foot-ſtalk. This ſort flowers in July and Auguſt.

The tenth ſort grows naturally near the ſea, about Marſeilles and Leghorn; this hath many thick fleſhy leaves, which are ſhaped like a ſpatula, growing near the root, and ſpread on the ground; they are ſmooth, and of a grayiſh colour. The ſtalks are naked, and riſe about ſix inches high, dividing toward the top into many ſmaller branches, which are terminated by ſhort crooked panicles of ſmall flowers, of a pale red colour. This ſort flowers in Auguſt, but never produces ſeeds in this country.

The eleventh ſort grows naturally about Montpelier and in Italy; this is an annual plant, with long narrow leaves, which are ſet with rough tubercles like the leaves of Viper's Bugloſs. The ſtalks riſe about eight inches high, dividing into two or three ſmall branches, which are terminated by reflexed ſhort ſpikes of pale blue flowers; theſe come out late in Auguſt, and the ſeeds are ſeldom perfected in England.

The twelfth ſort grows naturally in Egypt, from whence the ſeeds were ſent to the Royal Garden at Paris, part of which were ſent me by Dr. Bernard de Juſſieu, which grew in the Chelſea garden, where there are ſeveral plants, which have produced flowers many years. This riſes with an upright ſhrubby ſtalk to the height of eight or ten feet, divided upward into many branches, garniſhed with narrow ſpear-ſhaped leaves, placed without order; they are of a thick conſiſtence, and of a gray colour, ſitting cloſe to the branches. The flowers are produced at the end of the branches in looſe panicles, ſtanding alternate on each ſide the ſtalk, one above another, with intervals between them; they have pretty long tubes, which enlarge upward, where they are cut into five obtuſe ſegments, which ſpread open; theſe are of a bright ſky blue, but fade to a purple before they fall off. The flowers begin to appear in July, and there is a ſucceſſion of them till winter.

The firſt, ſecond, third, fourth, fifth, and eighth ſorts, are abiding plants, which will thrive in the open air in England; ſuch of theſe as grow naturally in England, may be eaſily procured from the places where they grow; theſe plants may be tranſplanted at almoſt any time of the year, provided they are carefully taken up, preſerving ſome earth to their roots, and in hot weather to ſhade them till they have taken new root; after which time they will require no other culture but to keep the ground clean from weeds, and in the ſpring to ſtir up the ground between them to looſen it. As theſe plants do not require much culture, nor do they take up much room, ſo a few of each ſort may be allowed to have a place in gardens, where there is room, for the ſake of variety. Theſe plants do not propagate very faſt in gardens, ſo the roots need not be removed oftener than every third or fourth year, at which time they may be ſlipped to increaſe them; the beſt time for this is in the autumn, that the plants may be well rooted before the ſpring, otherwiſe they will not flower very ſtrong the following ſummer. They ſhould be planted in a loamy ſoil, on an eaſt aſpected border, where they may enjoy the morning ſun, but ſcreened from the great heat in the middle of the day; in ſuch a ſituation the roots will continue ſeveral years, and flower as well as in their native ſoil.

Theſe plants may alſo be propagated by ſeeds, ſo that ſuch of them as do not grow naturally in England, may be obtained by procuring their ſeeds from abroad. Theſe ſhould be ſown upon a border expoſed to the morning ſun, and on a ſoft loamy ſoil, early in the ſpring, for the ſeeds lie a conſiderable time in the ground before the plant comes up; therefore the ground muſt be kept entirely clean from weeds, and if the ſeaſon ſhould prove very dry, the border ſhould be watered two or three times a week, otherwiſe the ſeeds will lie a whole year before they vegetate; when the plants come up, they muſt be kept clean from weeds, and in very dry weather watered, and in the autumn they may be tranſplanted where they are deſigned to remain.

The ſixth and eighth ſorts are biennial plants, which rarely perfect their ſeeds in England, ſo that unleſs freſh ſeeds can be procured from warm countries, where they ripen well, it will be very difficult to continue the ſorts. If the ſeeds of theſe can be obtained time enough to ſow them in the autumn, the plants will come up the following ſpring; but when they are ſown in the ſpring, they ſeldom grow the ſame year. Theſe ſeeds ſhould be ſown on a border of loamy earth, not ſtiff or moiſt, and expoſed to the ſouth; but when the ſun is warm, the border ſhould be ſhaded with mats, to prevent the earth from drying too faſt. When the plants come up, they muſt be kept clean from weeds; and if they are too cloſe, ſome of them ſhould be carefully taken out as ſoon as they are fit to remove, and planted in ſmall pots, placing them in the ſhade till they have taken new root; then they may be placed where they may enjoy the morning ſun till autumn, when they ſhould be put into a hot-bed frame, where they may be ſcreened from hard froſt, but enjoy the free air in mild weather; and thoſe plants which are left in the border where they were ſown, muſt be covered with mats in hard froſt; for though they will often live through the winter in mild ſeaſons, yet hard froſt will always deſtroy them. The following ſummer the plants will flower, and if the ſeaſon proves warm and dry, they will ripen ſeeds, and the roots ſoon after decay.

The ſeventh and twelfth ſorts are ſhrubby plants, which are too tender to live through the winter in the open air in England, ſo the plants muſt be removed into ſhelter in the autumn, but they only require protection from hard froſt: theſe plants may be placed with Myrtles, Oleanders, and other hardy green-houſe plants, where they often continue to flower great part of winter, and make a pretty variety. Theſe ſorts are eaſily propagated by cuttings, which, if planted in July on a ſhady border, and duly watered, will take root in ſix or ſeven weeks, when they ſhould be taken up and planted into pots filled with light loamy earth, placing them in the ſhade till they have taken root; then they may be expoſed till October, at which time they muſt be removed into ſhelter.

The eleventh ſort is annual, and rarely ripens ſeeds here, ſo theſe muſt be procured from abroad, and ſowed in the ſame way as the ſixth and eighth ſorts.

LINARIA. Tourn. Inſt. R. H. 168. tab. 76. Antirrhinum. Lin. Gen. Plant. 668. [ſo called of Linum, *Lat.* flax, becauſe its leaves reſemble flax.] Toad-flax; in French, *Linaire*.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, divided into five parts almoſt to the bottom. The flower hath one petal, and is of the ringent (or grinning) kind, with an oblong ſwelling tube, having two lips above, with the chaps ſhut. The upper lip is bifid and reflexed on the ſides, the lower lip is trifid and obtuſe. It hath an oblong nectarium, which is awl-ſhaped and prominent behind, and four ſtamina, which are included in the upper lip, two of which are ſhorter than the other, and a roundiſh germen ſupporting a ſingle ſtyle, crowned by an obtuſe ſtigma. The germen afterward turns to a roundiſh obtuſe capſule with two cells, filled with ſmall ſeeds.

This genus of plants is ranged in the fourth ſection of Tournefort's third claſs, which includes the herbs with a tubulous, anomalous, perſonated flower, of one petal. Dr. Linnæus joins this genus, and alſo the Aſarina of Tournefort to the Antirrhinum, and places that genus in the ſecond ſection of his fourteenth claſs, in which are contained the plants whoſe flowers have two long and two ſhort ſtamina, and the ſeeds are included in a capſule. The plants of this genus agree in their general characters with thoſe of the Antirrhinum, or Calve's Snout, except in one particular, which is in the nectarium of the Linaria, which, from the baſe of the petal, ſtretches out like a heel; whereas the flowers of the Antirrhinum, have their nectarium lodged withinſide the baſe of the petal: this being ſo very obvious, and both genera having many ſpecies, I thought it might be eaſier for ſtudents in botany to range them under different genera, than to join them under one.

The SPECIES are,

1. LINARIA (*Vulgaris*) foliis lanceolato-linearibus confertis caule erecto, ſpicis terminalibus ſeſſilibus. *Toad-flax with ſpear-ſhaped linear leaves growing in cluſters, and an upright ſtalk terminated by ſpikes of flowers, ſitting cloſe to the ſtalk.* Linaria vulgaris lutea, flore majore. C. B. P. 212. *Common yellow Toad-flax with a larger flower.*
2. LINARIA (*Triphylla*) foliis ternis ovatis. *Toad-flax with oval leaves placed by threes.* Linaria triphylla minor lutea. C. B. P. 212. *Smaller three-leaved yellow Toad-flax.*
3. LINARIA (*Luſitanica*) foliis quaternis lanceolatis, caule erecto ramoſo, floribus pedunculatis. *Toad-flax with ſpear-ſhaped leaves placed by fours, an upright branching ſtalk, and flowers upon foot-ſtalks.* Linaria latiſſimo folio Luſitanica. H. R. Par. *Broadeſt-leaved Portugal Toad-flax.*
4. LINARIA (*Alpina*) foliis ſubquaternis linearibus caule diffuſo, floribus racemoſis. *Toad-flax with linear leaves placed by fours on the lower part of the ſtalk, a diffuſed ſtalk and branching flowers.* Linaria quadrifolia ſupina. C. B. P. 213. *Low four-leaved Toad-flax.*
5. LINARIA (*Purpurea*) foliis lanceolato-linearibus ſparſis, caule florifero erecto ſpicato. *Toad-flax with ſpear-ſhaped linear leaves, and the flower-ſtalks erect and ſpiked.* Linaria purpurea major odorata. C. B. P. 213. *Greater ſweet-ſcented purple Toad-flax.*
6. LINARIA (*Repens*) foliis linearibus confertis, caule erecto ramoſo, floribus ſpicatis terminalibus. *Toad-flax with linear leaves in cluſters, an erect branching ſtalk, and flowers in ſpikes terminating the ſtalks.* Linaria cærulea, foliis brevioribus & anguſtioribus. Raii Syn. 3. 282. *Blue Toad-flax with ſhorter and narrower leaves.*
7. LINARIA (*Multicaulis*) foliis inferioribus quinis linearibus. *Toad-flax with linear leaves, placed by fives at the lower part of the ſtalks.* Linaria Sicula multicaulis, folio molluginis. Bocc. Rar. 38. *Sicilian Toad-flax with many ſtalks and a Bedſtraw leaf.*

8. Linaria (*Triſtis*) foliis lanceolatis ſparſis, inferioribus oppoſitis, nectariis ſubulatis, floribus ſubſeſſilibus. *Toad-flax with ſpear-ſhaped ſparſed leaves, which on the lower part of the ſtalk are oppoſite, awl-ſhaped nectariums, and flowers ſitting almoſt cloſe.* Linaria Hiſpanica procumbens, foliis uncialibus glaucis, flore flaveſcente pulchrè ſtriato, labiis nigro-purpureis. Act. Phil. N° 412. *Trailing Spaniſh Toad-flax with gray leaves an inch long, yellow flowers beautifully ſtriped, and dark purple lips.*

9. Linaria (*Monſpeſulana*) foliis linearibus confertis, caule nitido paniculato, pedunculis ſpicatis nudis. *Toad-flax with linear leaves in cluſters, a paniculated ſtalk, and flowers in ſpikes on naked foot-ſtalks.* Linaria capillaceo folio, odora. C. B. P. 213. *Sweet Toad-flax with hair-like leaves.*

10. Linaria (*Villoſa*) foliis lanceolatis hirtis alternis, floribus ſpicatis, foliolo calycino ſupremo maximo. *Toad-flax with alternate, hairy, ſpear-ſhaped leaves, flowers in ſpikes, and the upper leaf of the empalement very large.* Linaria latifolia villoſa, laciniis calycinis inæqualibus, flore majore pallido ſtriato rictu aureo. Horteg. Icon. *Broad-leaved hairy Toad-flax, whoſe empalement is unequally cut, and a large pale ſtriped flower with a golden ſnout.*

11. Linaria (*Peliſſeriana*) foliis caulinis linearibus ſparſis, radicalibus rotundis. *Toad-flax with linear leaves placed ſparſedly on the ſtalks, and on the lower leaves round.* Linaria annua purpureo violacea, calcaribus longis, foliis imis rotundioribus. Vaill. Bot. Par. 118. *Annual purple Violet Toad-flax, with long ſpurs and rounder leaves at bottom.*

12. Linaria (*Chalepenſis*) foliis lineari-lanceolatis alternis, floribus racemoſis, calycibus corollâ longioribus. *Toad-flax with linear ſpear-ſhaped leaves placed alternate, branching flowers, and empalements longer than the petals.* Linaria annua anguſtifolia, floſculis albis, longiùs caudatis. Triump. 87. *Narrow-leaved annual Toad-flax, with white flowers having long tails.*

13. Linaria (*Dalmatica*) foliis lanceolatis alternis, caule ſuffruticoſo. *Toad-flax with ſpear-ſhaped alternate leaves, and an under ſhrub ſtalk.* Linaria latifolia Dalmatica, magno flore. C. B. P. 212. *Broad-leaved Toad-flax of Dalmatia with a large flower.*

14. Linaria (*Geniſtifolia*) foliis lanceolatis acuminatis, paniculâ virgatâ. *Toad-flax with ſpear-ſhaped acute-pointed leaves, and a rod-like panicle.* Linaria geniſtæ folio glauco, flore luteo. Par. Bat. App. 9. *Toad-flax with a gray Dyer's Weed leaf and a yellow flower.*

15. Linaria (*Spuria*) foliis ovatis alternis, caule flaccido procumbente. *Toad-flax with oval leaves placed alternate, and a weak trailing ſtalk.* Elatine folio ſubrotundo. C. B. P. 253. *Fluellin with a roundiſh leaf.*

16. Linaria (*Elatina*) foliis haſtatis alternis, caule flaccido procumbente. *Toad-flax with arrow-pointed leaves placed alternate, and a weak trailing ſtalk.* Elatine folio acuminato. C. B. P. 253. *Fluellin with an acute-pointed leaf.*

17. Linaria (*Cymbalaria*) foliis cordatis quinquelobatis alternis glabris. *Toad-flax with heart-ſhaped leaves having five lobes, which are alternate and ſmooth.* Linaria hederaceo folio glabro, ſeu Cymbalaria vulgaris. Tourn. Inſt. R. H. 169. *Toad-flax with a ſmooth Ivy leaf, or common Cymbalaria.*

There are ſeveral other ſpecies of this genus which are well known and deſcribed, which are of leſs note, ſo are very rarely admitted into gardens, for which reaſon I have not enumerated them here.

The firſt of theſe plants grows in great plenty upon the ſides of dry banks in moſt parts of England, and is ſeldom cultivated in gardens; for it is a very troubleſome plant to keep within bounds, the roots being very apt to ſpread under ground, and riſe at a great diſtance from the mother plant, whereby it greatly injures whatever plants ſtand near it. This is one of the plants mentioned in the catalogue of ſimples at the end of the College Diſpenſatory, to be uſed in medicine.

This hath a great number of ſlender white roots, which creep far on every ſide, from which ariſe ſeveral erect branching ſtalks a foot and a half high, garniſhed with narrow gray leaves in cluſters, and terminated by ſpikes of yellow flowers, ſitting cloſe to the ſtalk. The flowers are of one petal, with a long tube, to which is fixed a ſpur or heel, called a nectarium; the fore parts of the flower has the appearance of the mouth of an animal, the under lip is hairy within; the chaps are of a golden colour, but the other parts of the flower are of a pale yellow; theſe are ſucceeded by roundiſh capſules with two cells, filled with flat black ſeeds. It flowers in July and Auguſt, when it makes a pretty appearance, ſo that a few plants might be allowed a place in gardens, were it not for their creeping roots, which ſpread too much, and become troubleſome weeds; therefore the roots ſhould be confined in pots to keep them within bounds.

There is an ointment made of this herb and hog's-lard, which is accounted excellent for the piles, being mixed with the yolk of an egg at the time of uſing it. The plant is reckoned to be aperitive and diuretic, opening obſtructions of the liver and ſpleen, helping the dropſy and jaundice.

The ſecond ſort grows naturally about Valencia and in Sicily; this is an annual plant, which riſes with an upright branching ſtalk near a foot and a half high, garniſhed with oval, ſmooth, gray leaves, placed often by threes, and ſometimes by pairs oppoſite at the joints; the flowers grow in ſhort ſpikes at the top of the ſtalks; they are ſhaped like thoſe of the common ſort, but have not ſo long tubes; they are yellow, with Saffron-coloured chaps. This ſort flowers in July and Auguſt, and the ſeeds ripen in the autumn, and the plants ſoon after decay.

There is a variety of this whoſe flowers have a purple ſtandard and ſpur, which makes a pretty appearance in a garden; but it is generally ſuppoſed to be only an accidental variety which has riſen from ſeeds of the former, for which reaſon I have not enumerated it here; though from many years culture of both ſorts, I have never yet perceived either of them alter. The leaves of this are longer than thoſe of the yellow, but in other reſpects they do not differ.

This ſort may be propagated by ſeeds, or by the roots; the ſeeds ſhould be ſown in the ſpring, on the borders of the flower-garden where they are deſigned to remain; and when the plants come up, they ſhould be thinned where they are too cloſe, and kept clean from weeds, which is all the culture they require. If ſome of the ſeeds are ſown in autumn upon a warm dry border, the plants will live through the winter, unleſs the froſt proves very ſevere; and theſe autumnal plants will grow larger, flower earlier, and from theſe good ſeeds may always be obtained: the firſt ſort is ſeldom admitted into gardens.

The third ſort riſes with upright ſtalks near two feet high, which are garniſhed with ſpear-ſhaped ſmooth leaves, placed ſometimes by fours round the ſtalk, and at others by pairs oppoſite; the ſtalks are terminated by large purple flowers with long ſpurs, ſtanding upon foot-ſtalks. This flowers in July, but ſeldom ripens ſeeds in England; it grows naturally in Portugal and Spain.

This ſort is tenderer than the laſt, ſo ſhould be planted in a dry ſoil and a warm ſituation, otherwiſe the plants are often deſtroyed in winter. This plant is propagated by ſeeds in the ſame manner as the former, as alſo by parting the roots; but it is adviſeable always to keep ſome of theſe plants in pots, that they may be removed into ſhelter in winter, otherwiſe in hard froſts they will be killed.

The fourth ſort grows naturally about Verona, from whence I received the ſeeds. This is a perennial plant, from whoſe roots ariſe ſeveral diffuſed ſtalks about eight inches long, garniſhed with narrow, ſhort, gray leaves, placed by fours round the ſtalks at bottom, but upward they are oppoſite; the ſtalks are terminated by ſhort branching tufts of pale yellow flowers with golden chaps. This ſort flowers in June, and in warm ſeaſons ſometimes the ſeeds will ripen here in the autumn.

The fifth ſort grows naturally in the ſouth of France and Italy; this hath a perennial root, ſending out many ſtalks; thoſe of them which ſupport the flowers are erect, and near three feet high, but the other ſtalks are weaker, and hang looſely on every ſide the plants; theſe are garniſhed with long, narrow, ſpear-ſhaped leaves placed ſparſedly; they are ſmooth, and of a gray colour. The ſtalks are terminated by long looſe ſpikes of blue flowers, which appear in June, July, and Auguſt, and the ſeeds ripen in the autumn, which, if permitted to ſcatter, will produce plenty of young plants without any further care.

The ſixth ſort grows naturally about Henley in Oxfordſhire, and alſo in ſome parts of Hertfordſhire. This hath a perennial root, from which ariſe ſeveral ſtalks near two feet high, which branch out on every ſide, and are garniſhed with narrow leaves growing in cluſters toward the bottom, but upward they are ſometimes by pairs, and at others ſingle. The flowers are produced in looſe ſpikes at the end of the ſtalks; they are of a pale blue colour, which appear in June and July, and the ſeeds ripen in the autumn; which, if permitted to ſcatter, will produce plenty of plants. When the ſeeds happen to fall upon old walls, the plants will grow there and continue longer than thoſe planted in the ground.

I received a ſpecimen of this ſort from abroad, by the title of Linaria arvenſis cærulea. C. B. P.

The ſeventh ſort grows naturally in Sicily; this is an annual plant, from whoſe root ariſes many ſtalks which are very ſlender and about a foot high, which on their lower part are garniſhed with five very narrow leaves at each joint, but upward they are ſometimes by pairs, and at others they are ſingle: the ſtalks are divided into many ſmall branches, which are garniſhed with ſmall yellow flowers, coming out ſingle at diſtances from each other; theſe are ſhaped like thoſe of the other ſpecies. The flowers appear in July, and the ſeeds ripen in the autumn. There are two varieties of this, one with a deep yellow, and the other a ſulphur-coloured flower.

This is propagated by ſeeds in the ſame manner as the ſecond ſort; if the ſeeds are permitted to ſcatter, the plants will come up without care, and if they are kept clean from weeds, will produce their flowers early in the ſummer.

The eighth ſort grows naturally on the rocks about Gibraltar, from whence the late Sir Charles Wager brought the ſeeds, which were ſown in his curious garden at Parſon's Green near Fulham, where they ſucceeded, and from thence many curious gardens were furniſhed with the plants. This has a perennial root, from which come out many ſlender ſucculent ſtalks about eight or nine inches long, which are weak and hang down on every ſide the root; they are garniſhed with ſhort, narrow, ſpear-ſhaped leaves, of a gray colour, and ſucculent, ſtanding without order; they are about one inch long, and a fifth part of an inch broad. The flowers are produced at the end of the ſtalks in ſmall bunches; they are yellow, marked with purple ſtripes, and the chaps of the flower, as alſo the ſpur, are of a dark purple colour; the flowers ſit cloſe upon the top of the ſtalk. They appear in June and July, but do not produce ſeeds in England.

This plant is eaſily propagated by planting cuttings in any of the ſummer months, which, if watered and ſhaded, will ſoon take root, and may be afterwards planted in pots, filled with freſh, light, undunged earth, in which they will ſucceed much better than in a richer ſoil; for if they are planted in a fine rich earth, it cauſes them to grow very faſt for a ſhort time, but they ſeldom fail to rot ſoon after. Theſe muſt be removed into ſhelter in winter, where they muſt have as much free air as poſſible in mild weather, and be only protected from ſevere cold; ſo that if the pots are placed under a hot-bed frame, the plants will ſucceed better than in a green-houſe, where they are apt to draw too much, which will cauſe them to decay.

The ninth ſort grows naturally in Wales, particularly near Penryn. This hath a perennial root, from which ariſe many branching ſtalks near two feet high, garniſhed with very narrow leaves growing in cluſters, which are of a grayiſh colour. The flowers are produced in looſe ſpikes at the end of the branches; they are of a pale blue colour, and ſmell ſweet. Theſe appear in June, and there is often a ſucceſſion of flowers on the plants till winter. The ſeeds ripen in the autumn, which, if permitted to ſcatter, will furniſh a ſupply of young plants without any further care. If the ſeeds of this ſort get on a wall, the plants will come up, and continue there a much longer time than when they are planted in the ground.

The tenth ſort grows naturally in Spain; the ſeeds of it were ſent me by Dr. Hortega from Madrid. This is an annual plant, which riſes with a ſingle ſtalk about a foot and a half high, garniſhed with hairy ſpear-ſhaped leaves, ſitting cloſe to the ſtalk, which are placed alternate. The flowers grow on the top of the ſtalks in looſe ſpikes; they are of a pale yellow colour, with a few dark ſtripes, and the chaps are of a gold colour; the upper ſegment of the empalement is much larger than the lower. The flowers of this ſort are as large as thoſe of the common ſort; they appear in July, and the ſeeds will in warm ſeaſons ripen in autumn in England.

The ſeeds of this ſort ſhould be ſown in the ſpring, upon a border of light earth where the plants are deſigned to remain; and when the plants come up, they muſt be treated in the ſame way as thoſe of the ſecond ſort.

The eleventh ſort grows naturally in France; this is an annual plant, having round leaves at the root; the ſtalks are ſlender, branching, and riſe a foot high, garniſhed with very narrow leaves at each joint. The flowers are produced in looſe ſpikes at the end of the branches; they are of a bright blue colour, and appear in July; the ſeeds ripen in the autumn, at which time they ſhould be ſown; for thoſe which are ſown in the ſpring frequently lie in the ground till the ſpring following, before the plants appear. When the plants come up, they muſt be thinned where they are too cloſe, and kept clean from weeds, which is all the culture they require.

The twelfth ſort grows naturally in Sicily; this is an annual plant, which riſes with a branching ſtalk two feet high, garniſhed with very narrow ſpear-ſhaped leaves placed alternately. The flowers are produced ſingly all along the branches the greateſt part of their length; they are ſmall, white, and have very long tails or ſpurs. This flowers in July, and the ſeeds ripen in the autumn. If the ſeeds of this ſort are permitted to ſcatter, the plants will come up and ſucceed better than if ſown with care, and require no other culture but to keep them clean from weeds.

The thirteenth ſort grows naturally in Crete, and alſo in Dalmatia. This riſes with a ſtrong ligneous ſtalk three feet high, garniſhed with ſmooth ſpear-ſhaped leaves placed alternate, ſitting cloſe to the ſtalk. The flowers are produced at the end of the branches in ſhort looſe ſpikes; they are of a deep yellow colour, and much larger than thoſe of the common ſort, ſtanding upon ſhort foot-ſtalks. This ſort flowers in July, but the ſeeds very rarely ripen in England, ſo that the plants are ſeldom ſeen in any gardens here. It is propagated by ſeeds, which ſhould be ſown early in the ſpring upon a border of light earth; and when the plants come up and are fit to remove, ſome of them ſhould be planted in pots filled with light ſandy earth, and placed in the ſhade till they have taken new root; then they may be expoſed with other hardy exotic plants till the end of October, when they ſhould be put into a common hot-bed frame, where they may be protected from hard froſt; but in mild weather they ſhould enjoy the free air, for theſe plants only require to be protected from hard froſt, for in mild winters they will live abroad without ſhelter, if they are upon a dry ſoil; therefore a part of the plants may be planted on a warm border of poor ſandy ſoil, where they will live through our common winters very well; and thoſe plants which grow in rubbiſh and are ſtinted, will endure much more cold than the others.

The fourteenth ſort grows naturally in Siberia; this is a biennial plant, which riſes with an upright branching ſtalk from three to four feet high, garniſhed with ſpear-ſhaped leaves, ending in acute points, of a grayiſh colour; theſe are placed alternate. The flowers are produced at the end of the branches, in looſe panicles; they are of a bright yellow colour, and ſhaped like thoſe of the other ſorts. This flowers in June and July, and the ſeeds ripen in the autumn, which, if permitted to ſcatter, the plants will come up the following ſpring, and require no other care but to thin them where they are too cloſe, and keep them clear from weeds. The plants always decay after they have ripened their ſeeds, therefore there ſhould be a ſupply of young ones annually raiſed.

The fifteenth ſort grows naturally amongſt Wheat and Rye, in ſeveral parts of England. It is an annual plant with weak trailing ſtalks, which ſpread on the ground, and are a foot and a half long; they are hairy, and garniſhed with oval leaves, placed alternately; from the ſetting on of the foot-ſtalks of the leaves; at each joint comes out one flower, ſhaped like thoſe of the other ſpecies. The upper lip is yellow, and the under is purple; theſe appear in June and July, and the ſeeds ripen in autumn, which ſhould be then ſown, or permitted to ſcatter; for if it is ſown in the ſpring, it ſeldom grows the ſame year, for it is rarely ſeen among ſpring-ſown Corn, in thoſe lands where it commonly grows.

This plant is uſed in medicine, and is eſteemed vulnerary, and good for old cancerous ſores and ulcers; it is accounted good for hæmorrhages of all ſorts.

The ſixteenth ſort differs from the fifteenth, in nothing but the ſhape of the leaves, which in this are ſhaped like the point of an arrow, and thoſe of the other are oval; this is more commonly found in England than the other.

The ſeventeenth ſort was brought from Italy to England, where it now grows in as great plenty in the neighbourhood of London, as if it was in its native country, growing from the joints of walls, whereever the ſeeds happen to ſcatter. It is a perenial plant, which will thrive in any ſoil or ſituation, ſo that where it is once eſtabliſhed, it will be difficult to root out, for the ſeeds will get into any joints of walls, or the decayed parts of pales, as alſo in the hollow of trees, where they grow and propagate plentifully; for the ſtalks put out roots at their joints, ſo ſpread themſelves to a great diſtance. It flowers all the ſummer, and the ſeeds ripen in ſucceſſion. It is never cultivated in gardens, but is ſuppoſed to be an excellent wound herb.

LINGUA CERVINA. Hart's Tongue.

Theſe plants commonly grow out from the joints of old walls and buildings, where they are moiſt and ſhady, and alſo upon ſhady moiſt banks, but are ſeldom cultivated in gardens. There is a very great variety of theſe plants, both in the Eaſt and Weſt-Indies, but there are very few ſpecies of them in Europe; all the hardy ſorts may be propagated by parting their roots, and ſhould have a moiſt ſoil and ſhady ſituation.

LINUM. Tourn. Inſt. R. H. 339. tab. 170. Lin. Gen. Plant. 349. Flax; in French, *Lin*.

The CHARACTERS are,

The flower hath a permanent empalement, compoſed of five ſmall, ſpear-ſhaped, acute leaves. It is compoſed of five large oblong petals, which are narrow at their baſe, but broader upward, and ſpread open. It hath five awl-ſhaped erect ſtamina, terminated by arrow-ſhaped ſummits. In the center is ſituated an oval germen, ſupporting five ſlender ſtyles, crowned by reflexed ſtigmas. The germen afterward turns to a globular capſule with ten cells, opening with five valves; in each cell is lodged one oval, plain, ſmooth ſeed, with an acute point.

This genus of plants is ranged in the fifth ſection of Linnæus's fifth claſs, intitled Pentandria Pentagynia, which contains thoſe plants whoſe flowers have five ſtamina and five ſtyles.

The SPECIES are,

1. LINUM (*Uſitatiſſimum*) calycibus capſuliſque mucronatis petalis crenatis, foliis lanceolatis alternis caule ſubſolitario. Lin. Sp. Plant. 277. *Flax with empalements, and capſules ending in acute points, crenated petals to the flower, ſpear-ſhaped alternate leaves, and the ſtalks commonly ſingle.* Linum ſativum. C. B. P. 214. *Manured Flax.*

2. LINUM (*Humile*) calycibus capſuliſque mucronatis, petalis emarginatis, foliis lanceolatis alternis, caule ramoſo. *Flax with ſharp-pointed empalements and capſules, the petals of the flower indented, ſpear-ſhaped alternate leaves, and a branching ſtalk.* Linum ſativum humilius flore majore. Bobart. Boerh. Ind. alt. 1. p. 284. *Low manured Flax with a larger flower.*

3. LINUM (*Narbonenſe*) calycibus acuminatis, foliis lanceolatis ſparſis ſtrictis ſcabris acuminatis, caule tereti baſi ramoſo. Lin. Sp. Plant. 278. *Flax with acute-pointed empalements, rough ſpear-ſhaped leaves placed without order, ending in acute points, and a taper ſtalk branching at the baſe.* Linum ſylveſtre, cæruleum, folio acuto. C. B. P. 107. *Wild blue Flax with an acute leaf.*

4. LINUM (*Tenuifolium*) calycibus acuminatis, foliis ſparſis linearibus ſetaceis retrorſum ſcabris. Lin. Sp. Plant. 278. *Flax with acute-pointed empalements, and narrow briſtly leaves placed without order, which are rough on their outſide.* Linum ſylveſtre anguſtifolium, floribus dilutè purpuraſcentibus vel carneis. C. B. P. 214. *Narrow-leaved wild Flax, with a pale purpliſh or fleſh-coloured flower.*

5. LINUM (*Anglicum*) calycibus capſuliſque acuminatis, caule ſubnudo ſcabro, foliis acuminatis. *Flax with acute-pointed empalements, an almoſt naked rough ſtalk, and acute-pointed leaves.* Linum perenne, majus, cæruleum, capitulo majore. Mor. Hiſt. 2. 573. *Greater blue perennial Flax with larger heads.*

6. LINUM (*Perenne*) calycibus capſuliſque obtuſis, foliis alternis lanceolatis acutis, caulibus ramoſiſſimis. Plat. 166. *Flax with obtuſe empalements and capſules, alternate, ſpear-ſhaped, acute leaves, and very branching ſtalks, commonly called Siberian perennial Flax.*

7. LINUM (*Hiſpanicum*) calycibus acutis, foliis lineari-lanceolatis ſparſis, caule paniculato procumbente. *Flax with acute empalements, linear ſpear-ſhaped leaves placed without order, and a paniculated ſtalk.*

8. LINUM (*Bienne*) calycibus patulis acuminatis, foliis linearibus alternis, caule ramoſo. *Flax with ſpreading acute-pointed empalements, linear alternate leaves, and a branching ſtalk.*

9. LINUM (*Hirſutum*) calycibus hirſutis acuminatis ſeſſilibus alternis, caule corymboſo. Lin. Sp. Plant. 277. *Flax with hairy acute-pointed empalements, placed alternate cloſe to the ſtalks, whoſe flowers are formed in a corymbus.* Linum ſylveſtre, latifolium, hirſutum cæruleum. C. B. P. 339. *Broad-leaved, hairy, wild Flax, with a blue flower.*

10. LINUM (*Strictum*) calycibus foliiſque lanceolatis ſtrictis mucronatis, margine ſcabris. Lin. Sp. Plant. 279. *Flax with ſpear-ſhaped leaves, and empalements which end in acute points, and have rough edges.* Paſſerina Lobelii. J. B. 3. p. 454.

11. LINUM (*Fruticoſum*) calycibus acutis, petalis integris, foliis inferioribus linearibus faſciculatis, ſuperioribus alternis, caule ſuffruticoſo. *Flax with acute empalements, entire petals to the flower, linear under leaves growing in cluſters, the upper ones alternate, and a ſhrubby ſtalk.* Linum ſylveſtre acutis foliis fruticans. Barrel. Icon. 1008. *Wild Flax with a ſhrubby ſtalk and acute leaves.*

12. LINUM (*Nodiflorum*) foliis lanceolatis alternis, floribus alternis ſeſſilibus caule ſimplici. *Flax with ſpear-ſhaped leaves placed alternate, flowers growing alternate, and cloſe to the ſtalks, which are ſingle.* Linum luteum ad ſingula genicula floridum. C. B. P. 214. *Yellow Flax with ſingle flowers growing from the joints.*

13. Linum (*Catharticum*) foliis oppoſitis ovato-lanceolatis, caule dichotomo, corollis acutis. Hort. Cliff. 372. *Flax with ſpear-ſhaped leaves placed oppoſite, a ſtalk divided by pairs, and acute petals to the flower.* Linum pratenſe, floſculis exiguis. C. B. P. 214. *Meadow Flax with ſmall flowers, commonly called Mountain Flax.*

14. Linum (*Maritimum*) calycibus ovatis acutis muticis, foliis lanceolatis inferioribus oppoſitis. Lin. Sp. Plant. 280. *Flax with oval, acute, chaffy empalements, and ſpear-ſhaped leaves, the lower of which grow oppoſite.* Linum maritimum luteum. C. B. P. 214. *Yellow maritime Flax.*

The firſt ſort is the Flax which is cultivated in moſt parts of Europe, but particularly in the northern parts; this is an annual plant, which uſually riſes with a ſlender unbranched ſtalk a foot and a half high, garniſhed with narrow ſpear-ſhaped leaves placed alternate, ending in acute points, and are of a gray colour. The flowers are produced on the top of the ſtalks, each ſtalk ſuſtaining four or five blue flowers, compoſed of five petals, which are narrow at their baſe, but broad at the top, where they are ſlightly crenated. The empalement of the flower is cut into five parts, which end in acute points. The flowers appear in June, and are ſucceeded by roundiſh capſules which have ten cells, opening with five valves, which are terminated by acute points; each cell contains one ſmooth flattiſh ſeed, ending in a point, of a browniſh colour. The ſeeds ripen in September, and the plants ſoon after periſh.

When this plant is cultivated in the fields after the uſual method, it ſeldom riſes higher than is before mentioned; nor do the ſtalks branch out, but when they are allowed more room, they will riſe more than two feet high, and put out two or three ſide branches toward the top, eſpecially if the ſoil is pretty good where it is ſown.

The ſecond ſort differs from the firſt, in having ſtronger and ſhorter ſtalks branching out much more. The leaves are broader, the flowers are larger, and the petals are indented at their extremities. The ſeed-veſſels are alſo much larger, and the foot-ſtalks are longer; theſe differences are laſting, for I have cultivated this and the common Flax on the ſame ground upward of thirty years, and have never found either of them alter.

The third ſort grows naturally in the ſouth of France, in Italy, and Spain; this riſes from a foot to eighteen inches high, branching out almoſt to the bottom into many long ſlender branches, which are garniſhed with narrow, ſpear-ſhaped, acute-pointed leaves, placed without order; theſe are rough to the touch. The flowers are produced at the end of the branches, almoſt in form of an umbel; they are ſmaller than thoſe of the manured ſort, and are of a pale blue colour. The ſeed-veſſels are much ſmaller, and not ſo round. It flowers and ſeeds about the ſame time as the former.

The fourth ſort grows naturally about Vienna and in Hungary; this ſort ſeldom riſes more than a foot high, with a ſlender ſtalk, which divides into three or four ſlender naked foot-ſtalks at the top, each ſuſtaining two or three flowers, which are of a pale blue colour. The ſtalks are garniſhed with ſhort, narrow, briſtly leaves, ſtanding erect, which are rough on their outſide. This flowers and ſeeds about the ſame time as the former, and the plant ſoon after decays.

There are two or three varieties of this, which differ in the colour of their flowers, but in other reſpects are the ſame.

The fifth ſort grows naturally in ſome parts of England, particularly in Cambridgeſhire; this hath a perennial root, from which ariſe three or four inclining ſtalks, garniſhed with ſhort narrow leaves toward their baſe, but upward have ſcarce any. The flowers are produced at the end of the ſtalks, ſitting very cloſe; they are of a blue colour, and about the ſize of thoſe of the manured kind, and are ſucceeded by pretty large round ſeed-veſſels, ending in acute points. This flowers about the ſame time as the common Flax, but the roots will continue four or five years.

The ſixth ſort grows naturally in Siberia; it hath a perennial root, from which ariſe ſeveral ſtrong ſtalks, in number proportional to the ſize of the root, and in height according to the goodneſs of the ſoil where it grows; for in rich moiſt ground they will riſe near five feet high, but in middling ground about three feet; theſe divide into ſeveral branches upward, and are garniſhed with narrow ſpear-ſhaped leaves, placed alternate; they are not much more than an inch long, and an eighth of an inch broad, of a deep green, ending in acute points. The flowers are produced at the end of the branches, forming a kind of umbel, the ſtalks riſing nearly of the ſame height. The flowers are large, and of a fine blue colour; theſe appear in June, and are ſucceeded by obtuſe ſeed-veſſels, which ripen in September.

The ſeventh ſort grows naturally in Spain, from whence I received the ſeeds; this hath a perennial root, from whence come out ſeveral trailing ſtalks, which are cloſely garniſhed with leaves; theſe never riſe much from the ground, but between theſe come out upright ſtalks, which riſe upward of two feet high, garniſhed with pretty long, narrow, ſpear-ſhaped leaves, placed without order. The flowers grow in a ſort of panicle toward the upper part of the branches; they are about the ſize of thoſe of the common ſort, and are of the ſame colour. It flowers and ripens its ſeeds about the ſame time, and the roots continue ſeveral years.

The eighth ſort I received from Iſtria; this hath a biennial root, from which ariſe two or three ſtalks, which divide into ſeveral branches, at about ſix inches from the root, which divide again into ſmaller toward the top; they are garniſhed with ſhort, narrow, acute-pointed leaves, placed alternately. The flowers come out from the ſide of the branches, ſtanding upon long foot-ſtalks. The empalement of the flower is compoſed of five broadiſh leaves ending in acute points, which ſpread open; the flowers are of the ſame ſize and colour as the common Flax, and appear at the ſame ſeaſon. The ſeeds ripen in the autumn, and the roots abide ſeveral years.

The ninth ſort grows naturally in Hungary and Auſtria; this hath a perennial root, from which ariſe ſeveral ſtalks near two feet high, which are thick, firm, and hairy, dividing at the top into ſeveral branches, and are garniſhed with broader leaves than the other ſpecies, which are hairy. The flowers grow along the ſtalks alternately; they are large, and of a deep blue colour, appearing at the ſame time with the common ſort, and the ſeeds ripen in the autumn.

The tenth ſort grows naturally in Germany and the ſouth of France, amongſt the Corn. This is an annual plant, riſing with an upright ſtalk near a foot and a half high, garniſhed with ſpear-ſhaped acute-pointed leaves, which are rough on their edges; they are about the ſame length of thoſe of the common Flax, but a little broader, placed alternately. The ſtalks divide toward the top into ſeveral branches, each ſuſtaining two or three yellow flowers, ſitting in ſpear-ſhaped acute-pointed empalements. Theſe appear in July, but unleſs the autumn proves favourable, the ſeeds never ripen in England.

The eleventh ſort grows naturally in Spain; the ſeeds of it were ſent me from Madrid by Dr. Hortega. This hath a ſhrubby ſtalk which riſes a foot high, ſending out ſeveral branches which are garniſhed with very narrow leaves coming out in cluſters; but the flowering branches are garniſhed with broader and longer leaves, placed alternately at every joint. The flowers are produced at the end of the branches, ſtanding erect upon long ſlender foot-ſtalks; they have acute-pointed empalements. The petals of the flower are large, entire, and white, but before the flowers open, they are of a pale yellow colour. Theſe flowers appear in July, but unleſs the autumn proves favourable, the ſeeds do not ripen in England. The flower-ſtalks of this ſort decay in the autumn, but the lower ſhrubby ſtalk continues with the other branches all the year.

The twelfth ſort grows naturally upon the Alps; this hath a perennial root, from whence ariſe two or three ſlender ſtiff ſtalks, which divide at the top into two or three ſlender branches, garniſhed with ſpear-ſhaped leaves placed alternately. The flowers come out ſingly at the joints, and ſit cloſe to the ſtalks; their empalements are cut into five ſlender ſegments, which are longer than the petals of the flower. The flowers are yellow, and appear about the ſame time with the common ſort, and the ſeeds ripen in the autumn.

The thirteenth ſort grows common in many parts of England, upon dry barren hills. It is commonly called Linum catharticum, purging Flax, and alſo Mountain Flax. This riſes with ſeveral branching ſlender ſtalks about ſeven or eight inches high, garniſhed with ſmall, oval, ſpear-ſhaped leaves placed oppoſite. The flowers are ſmall and white, ſtanding upon pretty long foot-ſtalks, which come out from the ſide of the branches, and alſo where they are divided. They appear in July, and are ſucceeded by ſmall round capſules, containing ſmall flat ſeeds which ripen in the autumn. This is one of thoſe plants which refuſes culture. I have frequently ſown the ſeeds both in autumn and ſpring, but could ſeldom get up any of the plants, and others who have made the trial have found the ſame.

The fourteenth ſort grows naturally about Montpelier, and in ſome parts of Italy near the ſea. This riſes with upright ſtalks near two feet high, the lower part of which are garniſhed with ſpear-ſhaped leaves placed oppoſite, but on the upper part they are alternate. The ſtalks divide upward into ſeveral branches, the tops of which are garniſhed with yellow flowers about the ſize of thoſe of common Flax, which hang downward; theſe are ſucceeded by ſmall oval capſules, containing ſmaller ſeeds than thoſe of the common Flax. The flowers appear in July, and the ſeeds ripen in the autumn.

There are ſeveral other ſpecies of Flax which grow wild in the different parts of Europe, but thoſe here enumerated are all I have ſeen growing in the Engliſh gardens.

The firſt ſort is that which is cultivated for uſe in divers parts of Europe, and is reckoned an excellent commodity; the right tilling and ordering of which, is eſteemed a good piece of huſbandry.

This ſhould be cultivated upon a rich ſoil, that has not been ploughed for ſeveral years, upon which Flax always makes the beſt improvement; but as it draws greatly from the ſoil, it ſhould not be ſown two years together upon the ſame ground, nor in leſs than after five or ſix years interval.

This ground ſhould be as clean from weeds as poſſible; in order to have it ſo, it ſhould be fallowed two winters and one ſummer, obſerving to harrow the ground well between each ploughing, particularly in ſummer, to deſtroy the young weeds ſoon after they appear, that the ſmalleſt of them may not ſtand to ripen their ſeed; this will alſo break the clods, and ſeparate their parts ſo, that they will fall to pieces on being ſtirred. If the land ſhould require dung, that ſhould not be laid on till the laſt ploughing, when it muſt be buried in the ground; but this dung ſhould be ſuch as is clear from the ſeeds of weeds, which it always will be where there is care taken to keep the dunghills clean from weeds, and the places near it; for ſuppoſing there ſhould be any ſeeds at firſt among the dung, yet when it is laid in a heap and well fermented, that will deſtroy the ſeeds; but there are few perſons who are careful to keep their dunghills, and the places near them, clean from weeds; and the ſeeds of theſe falling on the dung, are carried upon the land; from whence ſprung that vulgar error, that dung produces weeds, which it can never do, if there is not the ſeeds mixed with it. Juſt before the ſeaſon for ſowing of the Flax ſeed, the land muſt be well ploughed, laid flat and even, upon which the ſeeds ſhould be ſown about the latter end of March, or the beginning of April, when the weather is mild and warm.

The common way is to ſow the ſeed in broad-caſt, and to allow from two to three buſhels of ſeeds to one acre of land; but from many repeated trials, I have found it is a much better method to ſow the ſeeds in drills, at about ten inches diſtance from each other, by which half the quantity of ſeed which is uſually ſown, will produce a greater crop; and when the Flax is thus ſown, the ground may be eaſily hoed to deſtroy the weeds; which, if twice repeated in dry weather, will keep the ground clean till the Flax is ripe: this may be performed at half the expence which the hand weeding will coſt, and will not tread down the plants nor harden the ground, which by the other method is always done; and it is abſolutely neceſſary to keep the Flax clean from weeds, otherwiſe they will overbear and ſpoil the crop.

There are ſome people who recommend the feeding of ſheep with Flax, when it is a good height; and ſay, they will eat away the weeds and Graſs, and do the Flax good; and if they ſhould lie in it, and beat it down or flatten it, it will riſe again the next rain: but this is a very wrong practice, for if the ſheep gnaw or eat the Flax, the plants will ſhoot up very weak, and never come to half the ſize they would have done, if not cropped: and as to the ſheep deſtroying the weeds, they never are ſo nice diſtinguiſhers, for if they like the crop better than the weeds, they will devour that and leave the weeds untouched.

Toward the latter end of Auguſt or the beginning of September, the Flax will begin to ripen, when you muſt be careful that it does not ſtand to be over ripe; therefore you muſt pull it up as ſoon as the heads begin to change brown and hang downwards, otherwiſe the ſeeds will ſoon ſcatter and be loſt; ſo that the pluckers muſt be nimble, and tie it up in handfuls, ſetting them upright till they be perfectly dry, and then houſe them. If the Flax be pulled when it firſt begins to flower, it will be whiter than if it ſtand till the ſeed is ripe, but then the ſeed will be loſt; but the thread will be ſtronger when Flax is left till the ſeed is ripe, provided it does not ſtand too long, but the colour of it will not beſo good.

The Siberian perennial Flax has been made trial of, and anſwers very well for making of common ſtrong linen, but the thread ſpun from this is not ſo fine or white as that which is produced from the common ſort; but as the roots of this ſort will continue many years, ſo there will be a great ſaving in the culture, as it will require no other care but to keep it conſtantly clean from weeds; which cannot be well done, unleſs the ſeeds are ſown in rows, that the ground may be conſtantly kept hoed to deſtroy the weeds when young; for if they are ſuffered to grow large, it will be difficult to get the ground clean, and they will weaken the roots. This ſort muſt have the ſtalks cut off cloſe to the ground when ripe, and tied up in ſmall bundles, managing them afterward in the ſame way as the common ſort; but this ſeldom produces more than three crops, which will pay for ſtanding.

The eighth ſort I received from Iſtria, which produced the fineſt thread of all the ſorts which I have tried; and this grows taller than the common Flax, and having a biennial root, may be worthy of trial to ſee how it will thrive in the open fields; for in gardens it lives through the winter without receiving the leaſt injury from the froſt, the roots having ſurvived through the winter in the Chelſea garden ſeveral years; and in order to make trial of its goodneſs, I gave a parcel of the ſtalks of this, as alſo of the Spaniſh and Siberian perennial ſorts, to a perſon who is well ſkilled in watering, breaking, and dreſſing of Flax, who prepared them, and aſſured me, that the Iſtrian Flax was by much the fineſt of the three, and was in goodneſs preferable to any he had ſeen.

There is annually great quantities of the ſeed of Flax imported into Scotland and Ireland, from the Eaſt Country, particularly from Riga, to the amount of many thouſand pounds ſterling, per ann. which might be ſaved to the public, by encouraging the growth of Flax in the northern colonies of America, where the ſummers are warmer than in England, ſo that the ſeeds would ripen perfectly there, and the change of ſeeds from thence would be greater than that from Riga, but it ſhould be confined to the moſt northern parts of America; for ſuch ſeeds as are ſaved in the warmer parts will not ſucceed well here, as I have experienced in many other kinds of plants, whoſe ſeeds I have ſent to Carolina, where they have grown two or three years, after which ſome of the ſeeds have been ſent me back, which I have always found to be much longer in growing to perfection than before.

The other ſorts which are here mentioned, are preſerved in gardens for the ſake of variety, but none of them are uſed, except the Mountain Flax, which is eſteemed a good purger in dropſical diſorders, and has of late years been often preſcribed.

They are all of them propagated by ſeeds, which may be ſown in the ſpring, in the places where they are to remain, and will require no other culture but to keep the plants clean from weeds. The annual ſorts will flower and perfect their ſeeds the ſame year, but the roots of the perennial ſorts will continue ſeveral years, putting out freſh ſtalks every ſpring. The ſhrubby ſorts will live through the winter in the open air, provided it is in a dry ſoil and a warm ſituation; but theſe rarely produce ſeeds in England.

The method of watering, piling, braking, &c. being a particular buſineſs, and foreign to my deſign, I ſhall not pretend to give any directions about it in this place.

The common ſort is a plant of the greateſt uſe, in ſeveral of the moſt eſſential parts of life; from the ſeeds an expreſſed oil is drawn, which is of great uſe in medicine, painting, &c. from the bark of the ſtalks is made linen, and from the rags of linen is made paper; ſo that this plant may be eſteemed as one of the moſt valuable, and abſolutely neceſſary in many of the principal conveniencies of life.

LINUM UMBILICATUM. See Cynoglossum.

LIPPIA. Houſt. Gen. Nov. Lin. Gen. Plant. 699.

This plant was ſo named by the late Dr. William Houſtoun, who diſcovered it at La Vera Cruz, where it grows naturally, in honour of Dr. Auguſtus Lippi, a famous botaniſt, who travelled to Egypt, and diſcovered many new plants.

The Characters are,

The empalement of the flower is permanent, roundiſh, and compreſſed. The flower hath one petal, which is of the ringent kind; the upper lip is divided into two parts, which are reflexed; the under lip is ſmaller, and cut into two roundiſh ſegments. It hath four ſhort ſtamina, two of which are a little longer than the other, terminated by ſingle ſummits, and an oval germen ſupporting a ſlender ſtyle the length of the ſtamina, crowned by an indented ſtigma. The germen afterward turns to a compreſſed capſule with one cell, opening with two valves, which appear like the ſcales of the empalement, incloſing two ſeeds which are joined.

This genus of plants is ranged in the ſecond ſection of Linnæus's fourteenth claſs, intitled Didynamia Angioſpermia, which includes thoſe plants whoſe flowers have two long and two ſhorter ſtamina, and the ſeeds are included in capſules.

The Species are,

1. Lippia (*Americana*) arboreſcens foliis conjugatis oblongis, capitulis ſquamoſis & rotundis. Houſt. *Tree Lippia with oblong leaves growing by pairs, having round ſcaly heads.* Lippia capitulis pyramidatis. Lin. Sp. 883. *Lippia with pyramidal heads.*
2. Lippia (*Hemiſphærica*) capitulis hemiſphæricis. Jacq. Amer. 25. *Lippia with hemiſpherical heads.*

The firſt ſort in the country of its native growth, commonly riſes to the height of ſixteen or eighteen feet, with a rough bark: the branches come out by pairs oppoſite, as do alſo the leaves, which are oblong, pointed, and a little ſawed on their edges. From the wings of the leaves come out the foot-ſtalks, which ſuſtain many pyramidal ſcaly heads, about the ſize of a large gray Pea, in which are many ſmall yellow flowers appearing between the ſcales, which are ſucceeded by the ſeed-veſſels.

The ſecond ſort grows naturally in Carthagena in New Spain, where it riſes with ſhrubby ſtalks ten or twelve feet high, ſending out ſlender branches toward their top, garniſhed with oval ſpear-ſhaped leaves three inches long, ending in acute points, ſmooth on their upper ſurface, which are placed oppoſite; the foot-ſtalks of the flowers come out oppoſite juſt above the leaves, each ſupporting a pyramidal head of white flowers, which peep out from the ſcales of the head; theſe are ſucceeded by capſules having two cells, including ſmall ſeeds.

The ſeeds of the firſt ſort were ſent by Dr. Houſtoun to ſeveral curious gardens in Europe, where ſome of the plants have been raiſed; but as the country from whence they came is very warm, ſo the plants will not thrive in this climate, unleſs they are preſerved in a warm ſtove. The ſeeds ſhould be ſown on a hot-bed, and the plants may be treated in the ſame manner as other ſhrubby plants which are natives of warm countries: which is, to keep them always in the ſtove, plunged in the bark-bed, obſerving to give them a large ſhare of air in warm weather, and frequently refreſh them with water; but in winter they muſt be watered more ſparingly, and be kept in a moderate degree of warmth, otherwiſe they will not live through the winter, eſpecially while they are young; but when they have acquired ſtrength, they may be preſerved with a leſs ſhare of warmth.

As the plants advance in their growth, they ſhould be ſhifted into larger pots, but this ſhould not be too often repeated; for if they are removed into new pots every ſpring, it will be as often as they will require; ſo that when theſe, and many other exotic plants, are too often removed, they do not thrive ſo well as when they are permitted to fill the pots with their roots. The beſt time to ſhift theſe plants is in April, at which time the tan of the hot-bed ſhould be ſtirred, and freſh tan mixed with it, to increaſe the heat. The earth in which theſe plants are placed, ſhould be freſh and light, but not too rich.

LIQUIDAMBER. Mitch. Gen. 12. Lin. Gen. Plant. 955. Liquidamber, Sweet Gum, or Storax-tree.

The Characters are,

It hath male and female flowers ſometimes on the ſame plant, at other times upon different plants; the male flowers are numerous, diſpoſed in long, looſe, conical katkins; theſe have four-leaved empalements, but no petals. They have a great number of ſhort ſtamina joined in one body, which are convex on one ſide, but plain on the other, terminated by erect twin ſummits, with four furrows. The female flowers are often ſituated at the baſe of the male ſpike, collected in a globe; theſe have a double empalement like that of the male, and each of them has a bell-ſhaped, angular, diſtinct empalement, with many protuberances. They have no petals, but an oblong germen faſtened to the empalement, ſupporting two awl-ſhaped ſtyles, to which is alſo fixed the recurved ſtigmas, which are hairy and as long as the ſtyles. The empalement afterward turns to a roundiſh capſule of one cell, with two valves at the top, which are acute, and collected in a ligneous globe, containing oblong acute-pointed ſeeds.

This genus of plants is ranged in the eighth ſection of Linnæus's twenty-firſt claſs, which includes thoſe plants with male and female flowers, whoſe male flowers have many ſtamina.

The Species are,

1. Liquidamber (*Styraciflua*) foliis quinquelobatis ſerratis. *Liquidamber with ſawed leaves having five lobes.* Styrax aceris folio. Raii Hiſt. 1681. *Maple-leaved Storax-tree.*

2. **Liquidamber** (*Orientalis*) foliis quinquelobatis, ſinuatis obtuſis. *Liquidamber with leaves having five lobes, which are ſinuated and obtuſe.*

The firſt ſort has by ſome writers been ranged with the Maple, but on no other account, except from the ſimilitude of the leaves; for in flower and fruit it is very different from the Maple, and moſt other genera: nor has it any affinity to the Storax-tree, but the gum which iſſues from this tree being tranſparent, and having a great fragrancy, has by ſome ignorant perſons been taken for that.

It grows plentifully in Virginia and ſeveral other parts of North America, where it riſes with a ſtrait naked ſtem to the height of fifteen or ſixteen feet, and afterward branches out regularly to the height of forty feet or upward, forming a pyramidal head. The leaves are angular, and ſhaped ſomewhat like thoſe of the leſſer Maple, having five lobes, but are of a dark green colour, and their upper ſurfaces ſhining; a ſtrong, ſweet, glutinous ſubſtance exſudes through the pores of the leaves in warm weather, which renders them clammy to the touch.

The flowers are generally produced early in the ſpring of the year, before the leaves are expanded, which are of a Saffron colour, and grow in ſpikes from the extremity of the branches; after theſe are paſt, the fruit ſwells to the ſize of a Walnut, being perfectly round, having many protuberances, each having a ſmall hole and a ſhort tail, which extends half an inch.

The planks of this tree being beautifully veined, are often uſed in America for wainſcotting rooms; but it requires a long time to ſeaſon the boards, otherwiſe they are apt to ſhrink.

In Europe this tree is cultivated in the gardens of the curious, for the ſake of variety; it is hardy enough to endure the ſevereſt cold of this country in the open air, and there are ſome of them upward of twenty feet high, though I have not heard of any of them which has produced fruit.

This is commonly propagated by layers in England, but thoſe plants which are raiſed from ſeeds grow to be much fairer trees.

The ſeeds of this tree, if ſown in the ſpring, commonly remain in the ground a whole year before the plants come up; ſo that the ſureſt way to raiſe them is, to ſow the ſeeds in boxes or pots of light earth; which may be placed in a ſhady ſituation during the firſt ſummer, and in autumn they may be removed where they may have more ſun; but if the winter ſhould prove ſevere, it will be proper to cover them with Peas-haulm, or other light covering, which ſhould be taken off conſtantly in mild weather. In the following ſpring, if theſe boxes or pots are placed upon a moderate hot-bed, it will cauſe the ſeeds to come up early, ſo that the plants will have time to get ſtrength before the winter; but during the firſt and ſecond winters, it will be proper to ſcreen the plants from ſevere froſt, but afterward they will bear the cold very well.

The ſeeds of the ſecond ſort were ſent by Mr. Peyſſonel from the Levant, to the French king's garden at Marli, a few of which were ſent me by Mr. Richard, the king's gardener, which ſucceeded in the Chelſea garden. The leaves of this ſort differ from thoſe of the firſt, in having their lobes ſhorter, and much more ſinuated on their borders; they end in blunt points, and are not ſerrated; but as I have not ſeen the fruit of this, ſo I do not know how it differs from the other.

LIRIODENDRUM. See Tulipifera.

LITHOSPERMUM. Tourn. Inſt. R. H. 137. tab. 55. Lin. Gen. Plant. 166. [of Λίθος, a ſtone, and Σπέρμα, ſeed; q. d. Stone-ſeed; becauſe the ſeed of this plant is hard, and good againſt the ſtone.] Gromwell, Gromill, or Graymill; in French, *Gremil.*

The Characters are,

The flower hath an oblong, erect, acute-pointed, permanent, empalement, which is cut into five parts. It hath one petal with a cylindrical tube the length of the empalement, divided into five obtuſe points at the brim, which are erect; the chaps are perforated. It hath five ſhort ſtamina terminated by oblong ſummits, which are ſhut up in the chaps of the petal. It hath four germen, with a ſlender ſtyle the length of the tube, crowned by a bifid obtuſe ſtigma. The germen afterward turn to ſo many oval, hard, ſmooth, acute-pointed ſeeds, ſitting in the ſpreading empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, which includes the plants whoſe flowers have five ſtamina and one ſtyle.

The Species are,

1. **Lithospermum** (*Officinale*) ſeminibus lævibus, corollis calycem vix ſuperantibus, foliis lanceolatis. Hort. Cliff. 46. *Gromwell with ſmooth ſeeds, the petal of the flower ſcarce longer than the empalement, and ſpear-ſhaped leaves.* Lithoſpermum majus erectum. C. B. P. 258. *Greater upright Gromwell.*
2. **Lithospermum** (*Arvenſe*) ſeminibus rugoſis, corollis vix calycem ſuperantibus. Hort. Cliff. 46. *Gromwell with rough ſeeds, whoſe petals are ſcarce longer than the empalement.* Lithoſpermum arvenſe, radice rubrâ. C. B. P. 258. *Field Gromwell with a red root.*
3. **Lithospermum** (*Purpurocæruleum*) ſeminibus lævibus, corollis calycem multoties ſuperantibus. Hort. Cliff. 46. *Gromwell with ſmooth ſeeds, and the petal many times longer than the empalement.* Lithoſpermum minus repens latifolium C. B. P. 258. *Smaller, creeping, broad-leaved Gromwell.*
4. **Lithospermum** (*Virginianum*) foliis ſubovalibus nervoſis, corollis acuminatis. Lin. Sp. Plant. 132. *Gromwell with veined leaves which are almoſt oval, and acute-pointed petals.* Lithoſpermum latifolium Virginianum, flore albido longiore. Mor. Hiſt. 3. p. 447. *Broad-leaved Gromwell of Virginia with a longer whitiſh flower.*
5. **Lithospermum** (*Fruticoſum*) fruticoſum, foliis linearibus hiſpidis, ſtaminibus corollam ſubæquantibus. Lin. Sp. 190. *Shrubby Gromwell with rough linear leaves, and the ſtamina almoſt equal to the petal.* Bugloſſum ſamium fruteſcens, foliis Roriſmarini obſcure virentibus lucidis & hirſutis. Tourn. Cor. 6.

The firſt ſort grows naturally upon the banks, and in dry fields in many parts of England, ſo is ſeldom admitted into gardens. This hath a biennial root, from which ariſe two or three upright ſtalks two feet high, which branch out toward the top, garniſhed with ſpear-ſhaped, rough, hairy leaves, placed alternate, ſitting cloſe to the ſtalks. The flowers come out ſingly at every joint of the ſmall branches; they are white, of one petal, cut into four parts at the top, and ſtand within the empalement; theſe are ſucceeded by four hard, white, ſhining ſeeds, which ripen in the empalement. It flowers in May, and the ſeeds ripen in Auguſt.

The ſeeds of this plant are accounted a powerful diuretic, and a cleanſer of the reins and urethers, being boiled in wine and water, and are of great ſervice againſt gravel or ſtoppage of urine.

The ſecond ſort is an annual plant, which grows among winter Corn in many parts of England. This riſes with a ſlender branching ſtalk a foot and a half high, garniſhed with narrow, ſpear-ſhaped, rough leaves placed alternately. The flowers are produced ſingly on the upper parts of the ſtalks. They are ſmall and white; theſe are ſucceeded by four rough ſeeds, which ripen in the empalement. It flowers in June, and the ſeeds ripen in Auguſt, ſoon after which the plants decay.

The third ſort grows naturally in woods in many parts of England; this hath a perennial root, from which come out two or three trailing ſtalks ſcarce a foot long, garniſhed with long, narrow, ſpear-ſhaped leaves, placed alternately; theſe are ſmoother than thoſe of the other ſorts. The flowers are produced at the end of the ſtalks from amongſt the leaves; they are white, and the petals are much longer than the empalements. Theſe appear the latter end of May, and each is ſucceeded by four ſmooth ſeeds, which ripen in the empalement.

The fourth ſort grows naturally in North America; this hath a perennial root, from which ariſe ſeveral very hairy ſtalks about a foot and a half high, garniſhed with rough, hairy, veined leaves, which are almoſt oval, ſitting cloſe to the ſtalks alternately. The flowers grow in ſhort reflexed ſpikes at the end of the branches: theſe are white, their petals being longer than the empalement, ending in acute points. It flowers in June, and the ſeeds ripen in autumn.

The fifth ſort grows naturally in the ſouth of France, and alſo in the Levant. This hath a perennial root, which runs deep in the ground, from which comes out in the ſpring a ſhrubby erect ſtalk two or three feet high, which is pretty cloſely ſet with hairs, and garniſhed with narrow leaves placed alternately. The flowers are produced in ſhort reflexed ſpikes at the end of the ſtalk, ſtanding in hairy empalements; they are of a reddiſh purple colour, but as they decay change to a deep purple; they are tubulous, but cut at the top into four or five ſegments; the upper two are reflexed. It flowers in June, but the ſeeds rarely ripen in England.

Theſe plants may be cultivated by ſowing their ſeeds in rows ſoon after they are ripe, in a bed of freſh earth, allowing the rows at leaſt a foot diſtance from each other, obſerving to keep them clear from weeds, and they will thrive in almoſt any ſoil or ſituation.

LOAM is a common ſuperficial earth, that is a mixture of ſand and clay, commonly of a yellowiſh colour, though there is ſome Loam that is blackiſh. Some call Loam the moſt common ſuperficial earth met with in England, without any regard to the proportion it bears to ſand or clay; but moſt generally the appellation of Loam is applied to a ſoft fat earth, partaking of clay, but eaſy to work.

It is found by experience, that plants of moſt ſorts will grow in it; and wherever it is found, it appears to be a more beneficial ſoil to plants than any other. A clay uſed in grafting is alſo called Loam.

LOBELIA. Plum. Nov. Gen. 21. tab. 31. Lin. Gen. Plant. 897.

The CHARACTERS are,

The empalement of the flower is ſmall, of one leaf, indented in five parts, and grows about the germen. The flower has but one petal, which is tubulous, and a little ringent, cut into five parts at the brim; two of the upper ſegments are ſmaller than the other, are more reflexed and deeper cut, theſe conſtitute the upper lip; the three lower are ſpread open, and larger. It hath five awl-ſhaped ſtamina the length of the tube, terminated by oblong cylindrical ſummits, divided at their baſe into five parts. It has a pointed germen under the petal, ſupporting a cylindrical ſtyle, crowned by an obtuſe prickly ſtigma. The germen afterward becomes an oval fleſhy berry with two cells, each containing a ſingle ſeed.

This genus of plants is ranged in the fifth ſection of Linnæus's nineteenth claſs, to which he has joined the Rapuntium of Tournefort; but although the form of the flowers, and the number of their ſtamina, agree pretty well, yet as the fruit of this is a pulpy berry, incloſing but two ſeeds, and the Rapuntii have dry capſules including many ſmall ſeeds, I ſhall keep them ſeparate.

We know but one SPECIES of this genus, viz.

LOBELIA (*Fruteſcens*) fruteſcens, foliis ovati-oblongis integerrimis. Flor. Zeyl. 313. *Shrubby Lobelia with oblong, oval, entire leaves.* Lobelia fruteſcens portulacæ folio. Plum. Nov. Gen. 21. *Shrubby Lobelia with a Purſlane leaf.*

This plant riſes with a ſucculent ſtalk five or ſix feet high, garniſhed with oval, oblong, ſucculent leaves, which are placed alternately; theſe ſit cloſe to the ſtalk. The flowers are produced upon long foot-ſtalks, which come out from the ſide of the ſtalk, and ſuſtain two or three white flowers of one petal, cut into five acute ſegments at the brim; theſe are ſucceeded by two oval berries as large as Bullace, containing a ſtone with two cells, in each of which is lodged a ſingle ſeed.

The ſeeds of this plant were ſent to England by Mr. Cateſby, in the year 1724, who gathered them in the Bahama Iſlands, where the plants grow in plenty, near the ſhore of the ſea; and ſince that time the ſeeds have been ſent to England by Dr. William Houſtoun, who gathered them at La Vera Cruz; ſo that I believe the plant is common in moſt of the warm parts of America.

It is propagated by ſeeds, which muſt be procured from the countries of its natural growth, for the plants will not produce them in Europe; theſe ſeeds ſhould be ſown in pots filled with light ſandy earth, and plunged into a hot-bed of tanners bark, where the plants will come up in about a month or five weeks, provided the bed is warm, and the earth often watered. When the plants are up, they ſhould be kept in a temperate hot-bed, and frequently refreſhed with water, but it muſt not be given them in large quantities, for they are very ſucculent, and ſubject to periſh with much moiſture, eſpecially while they are young. When the plants are about two inches high, they ſhould be carefully taken out of the pots in which they were ſown, and each planted in a ſeparate ſmall pot filled with freſh light ſandy earth, and then plunged into the hot-bed again, obſerving to ſhade them in the heat of the day until they have taken new root. In this hot-bed the plants may remain until the middle, or latter end of September, when they muſt be removed into the ſtove, and plunged into the tan-bed, in the warmeſt part of the ſtove, for they are very tender plants while young, therefore muſt be kept very warm, otherwiſe they will not live through the firſt winter in this country. In the ſpring following the plants may be ſhifted into ſomewhat larger pots, and then plunged into a freſh hot-bed to forward their growth; for if they are not puſhed on while they are young, they ſeldom grow to any ſize, nor will they ever flower; ſo that in order to have them in any beauty, they muſt be carefully managed. The leaves of this plant are very ſubject to contract filth, by being conſtantly kept in the ſtove, therefore they ſhould be waſhed with a ſponge frequently, to keep them clean, otherwiſe they will appear unſightly.

LOBUS ECHINATUS. See GUILANDINA.

LOCULAMENTS are little diſtinct cells, or partitions, within the ſeed-veſſels of plants.

LOLIUM. Darnel Graſs.

Of this ſort of Graſs we have two or three ſpecies, which grow naturally in England; ſome in dry Graſs grounds, and one which is an annual Graſs, is frequently found in arable land; but as neither of them are cultivated for uſe, ſo I ſhall not trouble the reader with any farther account of them.

LONCHITIS [ſo called of Λόγχη, a lance or ſpear, becauſe the leaves are ſo ſharp-pointed as to reſemble the point of a ſpear.] Rough Spleenwort.

The CHARACTERS are,

The leaves are like thoſe of the Fern, but the pinnulæ are eared at their baſe; the fruit alſo is like that of the Fern.

The SPECIES are,

1. LONCHITIS aſpera. Ger. *Rough Spleenwort.*
2. LONCHITIS aſpera major. Ger. Emach. *Greater rough Spleenwort.*

The firſt of theſe plants is very common in ſhady woods, by the ſides of ſmall rivulets, in divers parts of England; but the ſecond ſort is not quite ſo common, and has been brought into ſeveral curious botanic gardens from the mountains in Wales. There are alſo great variety of theſe plants in America, which at preſent are ſtrangers in the European gardens; they are ſeldom cultivated but in botanic gardens for the ſake of variety, where they muſt have a moiſt ſoil and ſhady ſituation.

LONGITUDINAL VESSELS, in plants, are ſuch as are extended in length through the woody parts of trees and plants, into which the air is ſuppoſed to enter, and mix with the juices of the plant, and thereby augment its bulk.

LONICERA. Lin. Gen. Plant. Chamæceraſus. Tourn. Inſt. R. H. 609. tab. 379. *Upright Honeyſuckle.*

The Characters are,

The flower has a ſmall empalement, cut into five parts, upon which the germen ſits. It hath one petal, with an oblong tube, cut into five parts at the brim, and five awl-ſhaped ſtamina, almoſt the length of the petal, terminated by oblong ſummits. Under the petal is ſituated a roundiſh germen, ſupporting a ſlender ſtyle the length of the petal, crowned by an obtuſe ſtigma. The germen afterward turns to two berries, which join at their baſe.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, which includes thoſe plants whoſe flowers have five ſtamina and one ſtyle; and to this genus he has joined the Caprifolium, Periclymenum, and Xyloſteum of Tournefort, and the Symphoricarpos of Dillenius. Tournefort places this genus in the ſixth ſection of his twentieth claſs, in which he ranges the trees and ſhrubs with a flower of one petal, whoſe empalement becomes a berry.

The Species are,

1. Lonicera (*Xyloſteum*) pedunculis bifloris, baccis diſtinctis, foliis integerrimis pubeſcentibus. Prod. Leyd. 238. *Lonicera with two flowers on each foot-ſtalk, diſtinct berries, and entire woolly leaves.* Chamæceraſus dumetorum fructu gemino rubro. C. B. P. 451. *Dwarf Cherry with twin red fruit, commonly called Fly Honeyſuckle.*
2. Lonicera (*Alpigena*) pedunculis bifloris, baccis coadunatis didymis. Lin. Sp. Plant. 174. *Lonicera with two flowers upon a foot-ſtalk, and twin berries which are joined together.* Chamæceraſus Alpina, fructu gemino rubro duobus punctis notato. C. B. Elth. 371. *commonly called ſhrubby St. Peterſwort.*

The firſt ſort has been many years cultivated in the Engliſh gardens under the title of Fly Honeyſuckle. It grows naturally upon the Alps, and in other cold parts of Europe. It riſes with a ſtrong woody ſtalk ſix or eight feet high, covered with a whitiſh bark, dividing into many branches, which are garniſhed with oblong oval leaves placed oppoſite; they are entire, and covered with ſhort hairy down. The flowers come out on each ſide of the branches oppoſite, ſtanding upon ſlender foot-ſtalks, each ſuſtaining two white flowers ſtanding erect; theſe have one petal, which is cut into five parts; the three lower being narrow, are reflexed, the two broader ſtand upright; theſe appear in June, and are ſucceeded by two red clammy berries, which are joined at their baſe, and ripen the beginning of September.

The ſecond ſort grows naturally upon the Alps; this has been long cultivated in the Engliſh gardens, by the title of red-berried upright Honeyſuckle; this hath a ſhort, thick, woody ſtem, which divides into many ſtrong woody branches growing erect, garniſhed with ſpear-ſhaped leaves placed oppoſite, ſtanding upon foot-ſtalks; they are entire, their under ſide being of a pale green, but their upper of a dark green. The flowers ſtand upon very long ſlender foot-ſtalks, which come out oppoſite on each ſide the branches, at the baſe of the leaves; they are red on their outſide, but pale within, ſhaped like thoſe of the former ſort, but are a little larger, ſtanding erect; theſe appear the latter end of April, and are commonly ſucceeded by two oval red berries, joined at their baſe, which have two punctures; they ripen the beginning of Auguſt. Sometimes there is but one berry ſucceeding each flower, which is frequently as large as a Kentiſh Cherry; this I believe has led ſome to ſuppoſe it was a diſtinct ſpecies, as I thought myſelf, when I ſaw all the fruit upon the ſhrub were ſingle; but the following years, I found they had twin fruit like the others.

The third ſort grows naturally upon the Appenines; this is a ſhrub of humbler growth than either of the former, ſeldom riſing more than four or five feet high. The branches are ſlender, covered with a ſmooth purpliſh bark. The joints are diſtant, where the leaves come out oppoſite, and ſometimes there are two on each ſide. The foot-ſtalks of the flowers are very ſhort, each ſuſtaining two white flowers, ſhaped like thoſe of the former ſorts; theſe are ſucceeded by blue berries, which are ſingle and diſtinct. The flowers appear in May, and the berries ripen in Auguſt.

The fourth ſort grows naturally on the Alps and Helvetian Mountains; this is a ſhrub very like the former, but the branches are ſlenderer. The leaves are a little ſawed on their edges. The flowers have two berries ſucceeding them, in which conſiſts their difference. It flowers at the ſame time with the former.

The fifth ſort grows naturally in Tartary, from whence the ſeeds were ſent to the Imperial Garden at Peterſburgh, where they ſucceeded, and from thence the ſeeds were ſent to me; this is a ſhrub which grows about the ſame height with the two former, to which this has a great reſemblance in its branches; but the leaves of this are heart-ſhaped, and the berries are red, growing ſometimes ſingle, at others double, and frequently there are three joined together, which are about the ſame ſize with the former. It flowers in April, and the fruit is ripe in July.

The ſixth ſort grows naturally on the Pyrenean Mountains, and alſo in Canada, from whence the ſeeds were brought to Duke D'Ayen, which were ſown in his curious garden at St. Germain, where they ſucceeded, and his highneſs was ſo good as to furniſh me with a plant; this ſeldom riſes more than three or four feet high, dividing into ſeveral ſpreading irregular branches, which are garniſhed with oblong ſmooth leaves, placed oppoſite. The flowers come out from the ſide of the branches upon ſlender foot-ſtalks, each ſuſtaining two white flowers, which are cut into five ſegments almoſt to the bottom; theſe are ſucceeded by berries as the other ſorts. It flowers in April.

The ſeventh ſort grows naturally in North America, but has been many years propagated in the Engliſh gardens; this hath a ſhrubby ſtalk which riſes about four feet high, ſending out many ſlender plain branches, garniſhed with oval hairy leaves, placed by pairs oppoſite, having very ſhort foot-ſtalks. The flowers are produced in whorls round the ſtalk; they are of an herbaceous colour, and appear in Auguſt. The fruit, which is hollow, and ſhaped like a pottage pot, ripens in the winter. Dr. Dillenius, in his Hortus Elthamenſis, has titled this plant, Symphoricarpos foliis alatis, ſuppoſing the leaves to be winged;

but as the leaves fall off ſingle, and the branches remain upon which they were fixed, they cannot be called winged leaves.

Theſe ſhrubs are now propagated in the nurſery-gardens near London, for ſale, and are commonly intermixed with other flowering ſhrubs for the ſake of variety; but as there is little beauty in ſome of their flowers, a few of them only ſhould be admitted, to ſet off thoſe which are preferable; they are all of them very hardy plants, ſo will thrive in a cold ſituation better than in a warm one; they love a moiſt ſoil, in which they will thrive, and produce a greater quantity of fruit than in dry ground.

They may be propagated either by ſeeds or cuttings. The ſeeds commonly lie in the ground a year before they vegetate, but require no particular culture; if they are ſown in autumn, many of them will grow the following ſpring. The cuttings ſhould be planted in autumn in a ſhady border, where they will put out roots the following ſpring, and in the following autumn they may be removed into a nurſery, to grow two years to get ſtrength, after which they ſhould be tranſplanted where they are deſigned to remain.

LOPPING. It is very obſervable, that moſt old trees are hollow within, which does not proceed from the nature of the trees, but is the fault of thoſe who have the management of them, who ſuffer the tops to grow large before they lop them, as the Aſh, Elm, Hornbeam, &c. and perſuade themſelves, that they may have the more great wood; but, in the mean time, do not conſider that the cutting off great tops, or branches, endangers the life of a tree, or, at beſt, wounds it ſo, that many trees yearly decay more in their bodies, than the yearly tops come to; and at the ſame time that they furniſh themſelves with more great wood, they do it at the loſs of the owner. And, indeed, though the Hornbeam and Elm will bear great tops when the body is little more than a ſhell, yet the Aſh, if it comes to take wet at the head, very rarely bears more top after the body of the tree decays; therefore, if once theſe trees decay much in the middle, they will be worth little but for the fire, ſo that if you find a timber tree decay, it ſhould be cut down in time, that the timber be not loſt.

The Lopping of young trees, that is, at ten or twelve years old at moſt, will preſerve them much longer, and will occaſion the ſhoots to grow more into wood in one year, than they do in old tops at two or three. But when great boughs are ill taken off, it often ſpoils many a tree, for which reaſon they ſhould always be ſpared, unleſs there is an abſolute neceſſity. When they muſt be cut off, it ſhould be cloſe and ſmooth, and not parallel to the horizon, and cover the wound with loam and horſe-dung mixed, to prevent the wet from entering the body of the tree.

When trees are at their full growth, there are ſeveral ſigns of their decay, as, the withering or dying of many of their top branches; or if the wet enters at any knot, or they are any-wiſe hollow, or diſcoloured, if they make but poor ſhoots, or if woodpeckers make any holes in them.

This Lopping of trees is only to be underſtood for pollard trees, becauſe nothing is more injurious to the growth of timber trees, than that of Lopping or cutting off great branches from them; whoever will be at the trouble of trying the experiment upon two trees of equal age and ſize, growing near each other, to lop or cut off the ſide branches from one of them, and ſuffer all the branches to grow upon the other, will, in a few years, find the latter to exceed the other in growth every way, and this will not decay near ſo ſoon.

All ſorts of reſinous trees, or ſuch as abound with a milky juice, ſhould be lopped very ſparingly, for they are ſubject to decay when often cut. The beſt ſeaſon for Lopping theſe trees, is ſoon after Bartholomew tide, at which time they ſeldom bleed much, and the wound is commonly healed over before the cold weather comes on.

LORANTHUS. Vaill. Act. R. Sc. 1702. Lin. Gen. Plant. 400. Lonicera. Plum. Nov. Gen. 17. tab. 37.

The Characters are,

The empalement of the flower is entire, concave, and crowns the germen. The flower is tubulous, and cut into five narrow ſegments almoſt to the bottom, which are reflexed. It hath four ſtamina which are longer than the tube of the flower, terminated by globular ſummits. The germen, which is ſituated below the empalement, ſupports a ſingle ſtyle which is longer than the ſtamina, crowned by an oval ſtigma. The germen afterward becomes an oval pulpy fruit with one cell, including ſeveral compreſſed ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's ſixth claſs, but it ſhould be placed in his fourth claſs, for the flower has but four ſtamina and one ſtyle.

There are ſeveral ſpecies of this genus, which grow naturally upon trees, in ſeveral parts of America; but as the plants cannot be cultivated in gardens, ſo it will be to no purpoſe to enumerate them.

LOTUS. Tourn. Inſt. R. H. 402. Lin. Gen. Plant. 803. Bird's-foot Trefoil; in French, *Lotier*.

The Characters are,

The empalement of the flower is of one leaf, permanent, and cut at the top into five parts. The flower is of the butterfly kind. The ſtandard is roundiſh, and reflexed backward. The wings are broad, roundiſh, and ſhorter than the ſtandard, cloſing together at the top. The keel is cloſed on the upper ſide, and convex on the under, riſing a little. It hath ten ſtamina, nine joined and one ſeparate, terminated by ſmall ſummits, with an oblong taper germen, ſupporting a ſingle ſtyle, crowned by an inflexed ſtigma. The germen afterward becomes a cloſe cylindrical pod with one cell, opening with two valves, having many tranſverſe partitions, in each of theſe is lodged one roundiſh ſeed.

This genus of plants is ranged in the third ſection of Linnæus's ſeventeenth claſs, intitled Diadelphia Decandria, which contains the plants whoſe flowers have ten ſtamina in two houſes.

The Species are,

1. Lotus (*Corniculatus*) capitulis depreſſis, caulibus decumbentibus, leguminibus cylindricis patentibus. Lin. Sp. Plant. 775. *Bird's-foot Trefoil with depreſſed heads, trailing ſtalks, and cylindrical ſpreading pods.* Lotus corniculata glabra, minor. J. B. 2. 356. *Leſſer, ſmooth, corniculated Bird's-foot Trefoil.*
2. Lotus (*Anguſtiſſimus*) leguminibus ſubbinatis linearibus ſtrictis erectis, caule erecto, pedunculis alternis. Lin. Sp. Plant. 774. *Bird's-foot Trefoil with erect, linear, ſtrait pods, growing in pairs, an erect ſtalk, and alternate foot-ſtalks.* Lotus pentaphyllos, minor, hirſutus, ſiliquâ anguſtiſſimâ. C. B. P. 332. *Smaller, five-leaved, hairy Bird's-foot Trefoil, with very narrow pods.*
3. Lotus (*Glabrus*) capitulis depreſſis, caulibus decumbentibus, foliis linearibus glabris, leguminibus linearibus. *Bird's-foot Trefoil with depreſſed heads, trailing ſtalks, ſmooth linear leaves, and very narrow pods.* Lotus pentaphyllos fruteſcens, tenuiſſimis glabris foliis. C. B. P. 332. *Shrubby five-leaved Bird's-foot Trefoil, with very narrow ſmooth leaves.*
4. Lotus (*Rectus*) capitulis ſubgloboſis, caule erecto, leguminibus rectis glabris. Hort. Upſal. 221. *Bird's-foot Trefoil with globular heads, an erect ſtalk, and ſtrait ſmooth pods.* Lotus villoſus, altiſſimus, flore glomerato. Tourn. Inſt. R. H. 403. *Talleſt hairy Bird's-foot Trefoil with a glomerated flower.*
5. Lotus (*Cretica*) leguminibus ſubternatis, caule fruticoſo, foliis ſericeis nitidis. Hort. Cliff. 372. *Bird's-foot Trefoil with generally three pods on each foot-ſtalk, a ſhrubby ſtalk, and ſhining leaves.* Lotus argentea Cretica. Pluk. Alm. 226. *Silvery Bird's-foot Trefoil of Crete.*

6. Lotus (*Hirſutus*) capitulis hirſutis, caule erecto hirſuto, leguminibus ovatis. Hort. Upſal. 220. *Bird's-foot Trefoil with hairy heads, an erect hairy ſtalk, and oval pods.* Lotus pentaphyllos ſiliquoſus villoſus. C. B. P. 332. *Five-leaved, hairy, podded Bird's-foot Trefoil.*

7. Lotus (*Candidus*) capitulis ſubgloboſis hirſutis, caule erecto ramoſo, hirſuto, foliis tomentoſis. *Bird's-foot Trefoil with globular heads, which are hairy, an upright branching hairy ſtalk, and woolly leaves.* Lotus hæmorrhoidalis humilior & candidior. Tourn. Inſt. 403. *Lower bird's-foot Trefoil, having whiter leaves.*

8. Lotus (*Ornithopodioides*) leguminibus ſubquinatis arcuatis compreſſis, caulibus diffuſis. Hort. Cliff. 372. *Bird's-foot Trefoil with five arched compreſſed pods, and diffuſed ſtalks.* Lotus ſiliquis ornithopodii. C. B. P. 332. *Bird's-foot Trefoil with pods like birds feet.*

9. Lotus (*Peregrinus*) leguminibus ſubbinatis linearibus compreſſis nutantibus. Hort. Cliff. 372. *Bird's-foot Trefoil with two narrow compreſſed nodding pods.* Lotus ſiliquis geminis peregrina. Boerh. Ind. 2. p. 38. *Foreign Bird's-foot Trefoil with twin pods.*

10. Lotus (*Pratenſis*) leguminibus ſolitariis rectis teretibus terminalibus, caule erecto. Sauv. Monſp. 189. *Bird's-foot Trefoil with an erect ſtalk, terminated by a ſingle, taper, erect pod.* Lotus pratenſis ſiliquoſa lutea. C. B. P. 332. *Yellow, meadow, podded Bird's-foot Trefoil.*

11. Lotus (*Edulis*) leguminibus ſubſolitariis gibbis incurvis. Hort. Cliff. 370. *Bird's-foot Trefoil with ſingle, convex, incurved pods.* Lotus pentaphyllos, ſiliquâ cornutâ. C. B. P. 332. *Five-leaved Bird's-foot Trefoil with horned pods.*

12. Lotus (*Maritimus*) leguminibus ſolitariis membranaceo-quadrangulatis, bracteis lanceolatis. It. Oel. 143. Flor. Suec. 610. *Bird's-foot Trefoil with ſingle pods which are quadrangular by a membrane, and a ſpear-ſhaped bracteæ.* Lotus maritima lutea ſiliquoſa, folio pingui glabro. Bot. Monſp. *Podded, yellow, maritime Bird's-foot Trefoil with a ſmooth leaf.*

13. Lotus (*Conjugatus*) leguminibus conjugatis membranaceo quadrangulis, bracteis oblongo-ovatis. Lin. Sp. Plant. 774. *Bird's-foot Trefoil with conjugated pods which are quadrangular by a membrane, and oblong oval bracteæ.* Lotus lutea, ſiliquâ anguloſâ. Boerh. Ind. alt. 2. p. 37. *Yellow Bird's-foot Trefoil with angular pods.*

14. Lotus (*Tetragonolobus*) leguminibus ſolitariis membranaceo-quadrangulatis, bracteis ovatis. Hort. Upſal. 220. *Bird's-foot Trefoil with ſingle pods which are quadrangular, with a membrane, and oval bracteæ.* Lotus ruber ſiliquâ anguloſâ. C. B. P. 332. *Red Bird's-foot Trefoil with angular pods, commonly called winged Pea.*

15. Lotus (*Cytiſoides*) capitulis dimidiatis, caule diffuſo ramoſiſſimo, foliis tomentoſis. Prod. Leyd. 387. *Bird's-foot Trefoil with heads divided into two equal parts, a very branching diffuſed ſtalk, and woolly leaves.* Lotus ſiliquoſa maritima lutea, Cytiſi facie. Barrel. Icon. 1031. *Podded, yellow, maritime Bird's-foot Trefoil with the appearance of Cytiſus.*

16. Lotus (*Jacobæus*) leguminibus ſubternatis, caule herbaceo erecto, foliis linearibus. Hort. Cliff. 372. *Bird's-foot Trefoil with three pods, an erect herbaceous ſtalk and narrow leaves.* Lotus auguſtifolia, flore luteo purpuraſcente, inſulæ St. Jacobi. Hort. Amſt. 2. p. 165. *Narrow-leaved Bird's-foot Trefoil of St. James's iſland, with a yellow purpliſh flower.*

17. Lotus (*Dorycnium*) capitulis aphyllis, foliis ſeſſilibus quinatis. Lin. Sp. Plant. 776. *Bird's-foot Trefoil with naked heads, and leaves placed by fives ſitting cloſe to the branches.* Dorycnium Monſpelienſium. Lob. Icon. 51. *Dorycnium of Montpelier.*

The firſt, ſecond, and third ſorts grow naturally in many parts of England, ſo are rarely admitted into gardens. When theſe grow in moiſt land and a ſhady ſituation, they ſend out ſtalks near two feet long; but upon dry chalky and gravelly ground, their ſtalks are not more than four or five inches long, and lie flat upon the ground. I have always obſerved in thoſe paſtures where theſe plants have grown, that the cattle of all ſorts have avoided eating them, but the Graſs all round them has been eaten very bare. I have cut the plants when young, and given it to various kinds of animals, but could never get them to eat it; and yet the ſeeds of theſe have been gathered and ſold by ſome quacks in huſbandry, under the title of Lady's Finger Graſs, to be ſown as an improvement to land for paſture.

The roots of theſe are perennial, ſo are difficult to get out when they have had long poſſeſſion of the land; and they produce great quantities of ſeeds, which is caſt about by the elaſticity of the pods when ripe, to a conſiderable diſtance; they flower in June, and the ſeeds ripen in September.

The fourth ſort grows naturally in the ſouth of France, in Italy, and Sicily; this has by ſome been ſuppoſed the Cytiſus of Virgil, but without foundation, for it does not anſwer the deſcription given of that plant. This hath a ſtrong perennial root, from which ariſe many upright ſtrong ſtalks from three to four feet high, covered with a purpliſh bark, and toward the top ſend out a few ſide branches; theſe are garniſhed at every joint by a trifoliate leaf, whoſe lobes are wedge-ſhaped; at the baſe of the footſtalk are placed two heart-ſhaped lobes ſitting cloſe to the branch; the leaves are hairy on their under ſide; the flowers are produced at the end of the branches almoſt in globular heads, ſitting cloſe to the foot-ſtalk: theſe are of a pale fleſh colour and appear in June, and are ſucceeded by ſmooth ſtrait pods almoſt an inch long, which change to a brown colour when ripe, and contain ſeveral roundiſh ſeeds which ripen in September. It is rarely cultivated but in botanic gardens for variety, but if any perſon has an inclination to cultivate this plant for feeding of cattle, it may be done in the ſame way as the Lucern, for which there is full directions in the article Medicago. It riſes eaſily from ſeeds, is very hardy, and will thrive on any light dry poor ground. Cows and horſes will eat this plant when green, but I have not tried if they will feed on it when made into hay.

The fifth ſort grows naturally in Syria and Crete; this riſes with ſlender ſtalks which require ſupport, from three to four feet high, ſending out a few ſide branches; theſe are garniſhed at each joint with neat ſhining ſilvery leaves which are trifoliate, and have two appendages at the baſe of their foot-ſtalks, as the other ſorts; they are in ſhape like the former, but a little ſmaller, and have an acute point at their top. The foot-ſtalks of the flowers, which are from two to three inches long, ariſe from the ſide of the branches, and ſuſtain heads of yellow flowers, which part in the middle, each head containing four or ſix flowers; theſe appear in May, June, and July, and are ſucceeded by long taper pods filled with roundiſh ſeeds which ripen in the autumn.

This ſort has a perennial ſtalk, but is too tender to live through the winter in the open air in England, ſo is kept in pots and removed into the green-houſe in autumn, and treated like other hardy exotic plants which only require protection from froſt, ſo want no artificial heat. It may be propagated by ſeeds, which if ſown on a bed of light earth in April, the plants will come up in about a month after, and in another month will be fit to remove; when they ſhould be each put into a ſeparate ſmall pot filled with freſh light earth, placing them in the ſhade till they have taken new root; then they may be removed to a ſheltered ſituation, where they may remain till autumn.

It may be alſo propagated by cuttings, which may be planted during any of the ſummer months, upon a bed of light earth, covering them cloſe with a bell or hand-glaſs, and ſcreening them from the ſun; in about five or ſix weeks they will have taken root, when they muſt be inured to bear the open air, and ſoon after may be planted in pots, and treated in the ſame way as the ſeedling plants.

The ſixth ſort grows naturally in the ſouth of France and Italy; this hath a perennial ſtalk, which riſes three feet high; when the roots are large, they frequently ſend up ſeveral of theſe ſtalks, eſpecially if the old ones are cut down; the ſtalks are hairy, and divide into ſeveral branches, which are cloſely garniſhed with hoary trifoliate leaves, having two appendages at the baſe of the ſtalk; the flowers are collected into heads ſitting upon pretty long foot-ſtalks, which come out of the ſide of the ſtalks. They have very hairy empalements, and are of a dirty white colour with a few marks of pale red. They appear in June and July, and are ſucceeded by ſhort thick pods of a Cheſtnut colour, containing ſeveral roundiſh ſeeds which ripen in the autumn. This is propagated by ſeeds in the ſame way as the laſt ſort; the plants will live through the winter in the open air in moderate winters, but it will be proper to keep one or two plants in pots to be ſheltered in winter, leſt thoſe abroad ſhould be deſtroyed by ſevere froſt.

The ſeventh ſort grows naturally in Sicily; this riſes with an upright woody ſtalk near three feet high, garniſhed with leaves like the ſixth, but they are much whiter, covered with a ſhort woolly down, as are alſo the ſtalks; the flowers grow in cloſe heads like the laſt, and are ſucceeded by ſhort pods, which contain many yellow ſeeds. It flowers in ſummer, and the ſeeds ripen in autumn. This is too tender to live in the open air in England through the winter, ſo the plants muſt be kept in pots and houſed during that ſeaſon. It is propagated in the ſame way as the fifth ſort, and requires the ſame culture.

The eighth ſort grows naturally in Sicily; this is an annual plant, which ſends out from the root many ſtiff ſtalks from one to two feet high, which divide into many branches growing diffuſed without any order, and are garniſhed with trifoliate leaves, having two appendages at their baſe; the foot-ſtalks of the flower riſe from the wings of the ſtalks; they are two or three inches long, terminated by a cluſter of yellow flowers, which are ſucceeded by flat pods two inches long, which are bent like an arch, and have many joints, ſeparating the cells in which the ſeeds are lodged. It flowers in July, and the ſeeds ripen in autumn, and the plants decay ſoon after.

This is propagated by ſeeds, which ſhould be ſown early in April upon an open bed or border expoſed to the ſun, where the plants are to remain: when they come up they muſt be thinned, leaving them near two feet aſunder, and afterwards they muſt be kept clean from weeds, which is all the culture they require.

The ninth ſort grows naturally in Spain and Portugal: this is an annual plant like the former, but doth not branch ſo much; the ſmall leaves are rounder at their ends, and they are ſmoother; the foot-ſtalks are ſhorter, and ſeldom ſuſtain more than two flowers; theſe are ſucceeded by two very narrow pods about two inches long, which hang downward. This requires the ſame culture as the former.

The tenth ſort grows naturally in the ſouth of France; this hath a perennial root, from which is ſent out ſeveral hairy ſtalks near a foot long, garniſhed with trifoliate hairy leaves, ſtanding upon ſhort foot-ſtalks, with two appendages at the baſe of the foot-ſtalk; the flowers ſtand upon pretty long foot-ſtalks ſingly, which riſe from the end of the branches; they have long hairy empalements, with two oblong acute-pointed leaves immediately under them. The flowers are yellow, ſtanding erect, and are ſucceeded by taper erect pods an inch and a half long. It flowers in June and July, and the ſeeds ripen in the autumn. It is propagated by ſeeds, which ſhould be ſown where the plants are to remain, and muſt be treated as the two former ſorts, but the roots of this will continue ſeveral years.

The eleventh ſort grows naturally in Sicily and Crete, where the pods are eaten by the poorer inhabitants when they are young. It alſo grows about Nice, from whence I received the ſeeds. This is an annual plant, from whoſe roots come out ſeveral trailing ſtalks a foot long, garniſhed at each joint with trifoliate roundiſh leaves, having appendages. The flowers ſtand ſingly upon long foot-ſtalks, which ariſe from the ſide of the branches; they are yellow and ſmall, and are ſucceeded by ſingle pods, which are thick, and arched with a deep furrow on the outſide. The flowers appear in June and July, and in warm ſeaſons the ſeeds ripen in the autumn, but in cold ſummers they will not ripen here. This muſt have the ſame culture as the annual ſorts before mentioned.

The twelfth ſort grows near the borders of the ſea in France, Spain, and Italy; this hath a perennial root, ſending out many ſlender ſtalks about a foot and a half long, which trail upon the ground, and are garniſhed with trifoliate leaves at each joint, which are ſmooth, and have two appendages to the baſe of the foot-ſtalk. The flowers ſtand ſingly, upon very long foot-ſtalks ariſing from the wings of the ſtalk; they are yellow, and are ſucceeded by ſingle pods near two inches long, having four leafy membranes running longitudinally at the four corners. This flowers in June and July, and the ſeeds ripen in the autumn. It is propagated by ſeed in the ſame way as the tenth ſort.

The thirteenth ſort grows naturally in the ſouth of France and Italy; this is an annual plant, from whoſe roots are ſent forth ſeveral branching ſtalks a foot long, garniſhed with trifoliate leaves, whoſe lobes are acute-pointed, and have two oblong oval appendages at the baſe of their foot-ſtalks: the foot-ſtalks of the flower ariſe from the wings of the branches, each ſuſtaining two yellow flowers, which are ſucceeded by taper pods near two inches long, having four leafy membranes running longitudinally their length. It flowers in July, and the ſeeds ripen in autumn. It is propagated by the ſeeds in the ſame way as the annual ſorts before mentioned.

The fourteenth ſort grows naturally in Sicily, but has been long cultivated in the Engliſh gardens; it was formerly cultivated as an eſculent plant. The green pods of it were dreſſed and eaten as Peas, which the inhabitants of ſome of the northern counties ſtill continue, but they are very coarſe, ſo not agreeable to the taſte of thoſe who have been accuſtomed to better fare.

It is an annual plant which is cultivated in the flower-gardens near London for ornament. This ſends out from the root ſeveral decumbent ſtalks about a foot long, garniſhed at each joint with trifoliate oval leaves, having oval appendages at the baſe of their foot-ſtalks; from each joint ariſe alternately the foot-ſtalks of the flowers, which are from two to three inches long, each ſuſtaining one large red flower at the top, with three leaves juſt under the flower. After the flower fades, the germen becomes a ſwelling taper pod two inches long, having four leafy membranes or wings running longitudinally. It flowers in June and July, and the ſeeds ripen in autumn.

The ſeeds of this ſort are commonly ſown in patches, five or ſix ſeeds being ſown near each other, in the borders of the pleaſure-garden, where they are deſigned to remain. If the ſeeds all grow, ſome of the plants may be pulled up, leaving only two or three in each patch, and afterward they will require no other care but to keep them clean from weeds.

The fifteenth ſort grows near the borders of the ſea, in the ſouth of France and Spain. This is a perennial plant, ſending out from the root many ſtalks, which branch out their whole length, and are garniſhed with roundiſh trifoliate leaves with two appendages; they are covered with a woolly down: the flowers ſtand upon ſhort foot-ſtalks, four or ſix growing in a divided head; they are yellow, and appear in July, and are ſucceeded by taper pods filled with roundiſh ſeeds, which ripen in autumn. This is propagated by ſeeds, which ſhould be ſown in the ſpring in the place where the plants are to remain, and muſt be treated in the ſame manner as the hardy perennial ſorts before mentioned.

The ſixteenth ſort grows naturally in the Iſland of St. James, from whence the ſeeds were firſt brought to Europe, but I have ſince received the ſeeds from the Cape of Good Hope. This hath a ſlender ſtalk which is woody, riſing from two to three feet high, ſending out many ſlender herbaceous branches, garniſhed with narrow white leaves, which are ſometimes trifoliate, and at others there are five narrow lobes to each; theſe ſit cloſe to the branches, and are hoary. The flowers are produced from the ſide of the ſtalks towards their upper part, upon very ſlender foot-ſtalks, each ſuſtaining four or five flowers collected in a head, of a yellowiſh deep purple colour, which are ſucceeded by taper ſlender pods little more than an inch long, containing five or ſix ſmall roundiſh ſeeds. This plant flowers all the ſummer and autumn, and many times great part of the winter, eſpecially if the plants are placed in a dry airy glaſs-caſe, where they may be free from damp, for nothing is more prejudicial to them. It is too tender to live abroad in England, ſo the plants muſt be kept in pots; and in the winter placed in a warm airy glaſs-caſe, but in the ſummer they ſhould be placed abroad in a ſheltered ſituation. It may be eaſily propagated by cuttings, during the ſummer ſeaſon, in the ſame way as the fifth ſort, and alſo by ſeeds; but the plants which have been two or three times propagated by cuttings, ſeldom are fruitful.

The ſeventeenth ſort grows naturally about Montpelier; it riſes with weak ſhrubby ſtalks three or four feet high, ſending out many ſlender branches, which are thinly garniſhed with ſmall hoary leaves, growing with five lobes in form of a hand; they ſit cloſe to the branches. The flowers are produced at the extremity of the branches in ſmall heads; they are very ſmall and white, ſo make no great appearance; they appear in June, and are ſucceeded by ſhort pods containing two or three ſmall round ſeeds which ripen in the autumn. This ſhrub will live in the open air, if it be planted in a dry ſoil and a warm ſituation. It is propagated by ſeeds, which will come up in any common border.

LOTUS ARBOR See Celtis.

LOVE-APPLE. See Lycopersicon.

LUDVIGIA. Lin. Gen. Plant. 142.

This title was given to this genus of plants by Dr. Linnæus, in honour of M. Chriſt. Ludwig, of Leipſic, who publiſhed Remarks on Rivinus's Method of claſſing Plants, at Leipſic, in 1737.

The Characters are,

The empalement of the flower is of one leaf, cut into four ſegments at the top, and ſits upon the germen. The flower conſiſts of four ſpear-ſhaped petals, which are equal, and ſpread open. In the center of the flower is ſituated the four-cornered pointal, attended by four ſtamina: the germen afterward becomes a four-cornered fruit, crowned with the empalement, and has four cells which are full of ſmall ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's fourth claſs, which includes thoſe plants whoſe flowers have four ſtamina and one ſtyle.

We have but one Species of this genus in the Engliſh gardens at preſent, which is

Ludvigia (*Alternifolia*) foliis alternis lanceolatis. Lin. Sp. Plant. 118. *Ludvigia wich alternate ſpear-ſhaped leaves.* Ludvigia capſulis ſubrotundis. Hort. Cliff. 491. *Ludvigia with roundiſh capſules.*

We have no Engliſh name for this plant, but it is very near akin to the Onagra, or Tree Primroſe, from which it differs in the number of ſtamina.

This plant grows naturally in South Carolina, from whence the late Dr. Dale ſent me the ſeeds. It is annual, and riſes with an upright branching ſtalk a foot high, garniſhed with ſpear-ſhaped leaves placed alternate. The flowers come out ſingly at the foot-ſtalks of the leaves; they are compoſed of four ſmall yellow petals, which ſpread open, ſtanding upon ſhort foot-ſtalks, and have four ſtamina; the flowers are ſucceeded by roundiſh ſeed-veſſels with four leafy membranes they open in four cells, including many ſmall ſeeds. It flowers in July, and the ſeeds ripen in the autumn. The plants muſt be raiſed in a hot-bed in the ſpring, and treated in the ſame manner as hath been directed for the Amaranthus; for if they are not brought forward in the ſpring, they ſeldom produce good ſeeds in England.

LUFFA. Tourn. Act. R. S. 1709. Momordica. Lin. Gen. 967. Egyptian Cucumber.

The Characters are,

It hath a bell-ſhaped flower conſiſting of one leaf, which is divided into five parts to the center; there are male and female flowers on the ſame plant. The male flowers are produced on ſhort foot-ſtalks, having no embryos; but the female flowers reſt on the top of the embryos, which afterward become a fruit like a Cucumber to outward appearance, but is not fleſhy; the inner part conſiſting of many fibres, which are elegantly netted; and there are three cells which are filled with ſeeds, which are almoſt of an oval ſhape.

We have but one Species of this plant, viz.

Luffa (*Ægyptiaca*) Arabum. Tourn. Act. R. 170. *The Luffa of the Arabians.*

There are two varieties of this plant, one having white, and the other black ſeeds; but theſe are not diſtinct ſpecies.

This plant may be propagated after the ſame manner as Cucumbers and Melons, by ſowing the ſeeds on a hot-bed the beginning of March; and when the plants are come up, they muſt be pricked into a freſh hot-bed to ſtrengthen the plants, obſerving to let them have freſh air every day in warm weather, and to refreſh them frequently with water. When the plants have four or five leaves, they ſhould be planted out upon a hot-bed where they are deſigned to remain, which ſhould be under frames, and but one plant put into each light; for as theſe plants ſend forth a great number of ſide-ſhoots, ſo where they are planted too cloſe, they will entangle one into the other, and become ſo thick, as to cauſe the fruit to drop. In the management of theſe plants, after they are planted out for good, there muſt be the ſame care taken as for Melons and Cucumbers, with this difference only, that theſe require a larger ſhare of air in warm weather; otherwiſe the Vines will grow weak, and will not produce fruit.

When the plants have ſpread, ſo as to fill the frames on every ſide, the frames ſhould be raiſed on bricks, and the ends of the plants drawn out, that they may have room to grow; for when theſe plants are in a vigorous ſtate, they will ſpread eight or ten feet; ſo that if they are confined, they will become ſo thick, as to rot the tender branches which are covered from the air, and there will be no fruit produced.

The fruit, when it is young, is by ſome people eaten, and made into Mangoes, and preſerved in pickle; but it hath a very diſagreeable taſte, and is not accounted very wholeſome: wherefore theſe plants are ſeldom cultivated in Europe, except by ſuch perſons as are curious in botany, for variety.

LUNARIA. Tourn. Inſt. R. H. 218. tab. 105. Gen. Plant. 725. [ſo called of Luna, *Lat.* the moon. becauſe the ſeed-veſſels reſemble the form of the moon.] Moonwort, Sattin Flower, or Honeſty; in French, *Bulbonac.*

The Characters are,

The empalement of the flower is compoſed of four oblong, oval, ſmall leaves, which are obtuſe and fall off; the flower has four petals in form of a croſs, which are large, obtuſe, and entire: it hath ſix awl-ſhaped ſtamina, four of theſe are the length of the empalement; the other two are ſhorter, terminated by erect ſummits. It has an oblong oval germen ſitting upon a ſmall foot-ſtalk, ſupporting a ſhort ſtyle, crowned by an entire obtuſe ſtigma. The germen afterward becomes an erect, plain, compreſſed, elliptical pod, ſitting upon the ſmall foot-ſtalk, terminated by the ſtyle, having two cells opening with two valves, which are parallel, incloſing ſeveral compreſſed kidney-ſhaped ſeeds, which are bordered, ſitting in the middle of the pod.

This genus of plants is ranged in the ſecond ſection of Linnæus fifteenth claſs, intitled Tetradynamia ſiliculoſa, which includes thoſe plants whoſe flowers have four long and two ſhorter ſtamina, and the ſeeds are included in ſhort pods.

The Species are,

1. Lunaria (*Rediviva*) ſiliculis oblongis. Lin. Sp. Plant. 653. *Sattin Flower with oblong pods.* Lunaria major, ſiliquâ longiore. J. B. 2. 881. *Greater Moonwort with longer pods, commonly called Honeſty, or White Sattin.*
2. Lunaria (*Annua*) ſiliculis ſubrotundis. Lin. Sp. Plant. 653. *Sattin Flower with roundiſh pods.* Lunaria major, ſiliquâ rotundiore. J. B. *Greater Moonwort with a rounder pod.*
3. Lunaria (*Ægyptiaca*) foliis ſuprà decompoſitis, foliolis trifidis, ſiliculis oblongis pendulis. *Moonwort with leaves decompounded whoſe lobes are trifid, and oblong hanging pods.* Cardamine foliis ſuprà decompoſitis, ſiliquis unilocularibus pendulis. Lin. Sp. Plant. 656. *Lady's Smock with leaves decompounded above, and hanging pods containing one cell.*
4. Lunaria (*Perennis*) perennis, ſiliculis oblongis, foliis lanceolatis incanis. *Perennial Moonwort, with oblong pods and ſpear-ſhaped hoary leaves.* Lunaria perennis, lutea, folio leucoii, ramis expanſis. Vaill. *Yellow perennial Moonwort, with a Stock Gilliflower leaf and expanded branches.*

The firſt ſort grows naturally in Hungary, Iſtria, and Auſtria, but has been long an inhabitant of the Engliſh gardens. It is a biennial plant, which periſhes ſoon after the ſeeds are ripe; it riſes with a branching ſtalk from two to three feet high, covered with a reddiſh hairy bark, ſending out branches on every ſide from the ground upward; theſe are garniſhed with heart-ſhaped leaves placed alternately, ending in acute points indented on their edges, and are a little hairy; the lower ſtanding upon pretty long foot-ſtalks, but the upper ſit cloſe to the branches. The flowers are produced at the top and from the ſide of the branches toward their ends, in cluſters; they are compoſed of four purpliſh heart-ſhaped petals, placed in form of a croſs. Theſe appear in May, and are ſucceeded by large flat roundiſh pods with two cells, incloſing two rows of flat kidney-ſhaped ſeeds, which have a border round them. Theſe pods, when ripe, turn to a clear white or ſattin colour, from whence the title of Sattin Flower has been given to it, and are tranſparent.

The ſeed-veſſels of this plant, when they are full ripe, become very tranſparent, and of the appearance of white ſattin, at which time the branches are cut off and dried; after which they are preſerved to place in the chimneys of halls and large rooms, where they continue a long time in beauty.

This is propagated by ſeeds, which ſhould be ſown in the autumn; for thoſe which are ſown in the ſpring often miſcarry, or lie a long time in the ground before they appear. The plants will grow in almoſt any ſoil, but love a ſhady ſituation; it requires no other culture, but to keep it clean from weeds. If the ſeeds are permitted to ſcatter, the plants will riſe without any farther care; and if they are left unremoved, they will grow much larger than thoſe which are tranſplanted; the roots of this ſort periſh ſoon after the ſeeds are ripe.

The ſecond ſort grows naturally upon the mountains in Italy; this hath ſtalks and leaves very like the firſt, but the flowers are rather larger, and of a lighter purple colour; but the principal difference is in the pods of this being longer and narrower than thoſe of the other. It flowers and ſeeds at the ſame time with the firſt, and requires the ſame culture.

The third ſort is an annual plant, which grows naturally in Egypt. This riſes with a ſmooth branching ſtalk little more than a foot high, garniſhed with winged leaves, compoſed of ſeveral pair of lobes ranged along the midrib, terminated by an odd one; theſe lobes are of unequal ſizes, and vary in their form; ſome of them are almoſt entire, and others are cut at their extremities into three parts; they are ſmooth, and of a lucid green. The flowers ſtand each upon pretty long ſlender foot-ſtalks, which come out from the ſide, and alſo at the end of the branches, in looſe ſmall cluſters; they are of a purple colour, and are ſucceeded by oblong compreſſed pods, which hang downward. This ſort flowers in June and July, the ſeeds ripen the beginning of September, and the plants decay ſoon after.

This is propagated by ſeeds, which ſhould be ſown upon an open border where the plants are to remain; if they are ſown ſoon after they are ripe, the plants will come up in the autumn, and live through the winter in a ſheltered ſituation; theſe will flower early the following ſummer, whereby ripe ſeeds may be obtained; they may alſo be ſown in the ſpring in like manner. When the plants come up, they will require no other care but to keep them clean from weeds, and thin them where they are too cloſe. If the ſeeds are permitted to ſcatter in the autumn, the plants will riſe without care, and may be treated in the ſame way, which is much preferable to the ſowing the ſeeds in the ſpring.

The fourth ſort grows naturally in the Archipelago; this hath a perennial root, from which ariſe two or three ligneous ſtalks a foot high, covered with a white hairy bark, dividing upward into ſeveral ſmaller branches, garniſhed with ſpear-ſhaped leaves ſitting cloſe to the ſtalks, which are a little hoary. The branches are terminated by looſe ſpikes of yellow flowers which appear in June, and are ſucceeded by oblong flat pods, containing flat kidney-ſhaped ſeeds, which ripen in the autumn.

This ſort is propagated by ſeeds, which, if ſown in the autumn, will ſucceed better than in the ſpring; they ſhould be ſown on a warm border, and on a dry poor ſoil, otherwiſe they will not live through the winter; but in a rubbiſhing ſoil the plants will continue two or three years.

LUPINUS. Tourn. Inſt. R. H. 392. tab. 213. Lin. Gen. Plant. 774. Lupine; in French, *Lupin*.

The Characters are,

The empalement is bifid and of one leaf; the flower is of the butterfly kind; the ſtandard is roundiſh, heart-ſhaped, indented at the top, and the ſides reflexed and compreſſed. The wings are nearly oval, and almoſt as long as the ſtandard; they are not fixed to the keel, but cloſe at their baſe; the keel is as long as the wings, but is narrow, falcated, and ends in a point. It hath ten ſtamina joined at their baſe in two bodies, but as they riſe are diſtinct above, terminated by five oblong ſummits. In the center is ſituated a hairy, compreſſed, awl-ſhaped germen, ſupporting a riſing ſtyle, terminated by an obtuſe ſtigma. The germen afterward becomes a large, oblong, thick pod with one cell, ending with an acute point, including ſeveral roundiſh compreſſed ſeeds.

This genus of plants is ranged in the third ſection of Linnæus's ſeventeenth claſs, intitled Diadelphia Decandria, which includes thoſe plants whoſe flowers have ten ſtamina joined in two bodies.

The Species are,

1. Lupinus (*Varius*) calycibus ſemiverticillatis appendiculatis, labio ſuperiore bifido, inferiore ſubtridentato. Hort. Cliff. 499. *Lupine with empalements half whorled, having appendages, whoſe upper lip is bifid, and the under one almoſt trifid.* Lupinus ſylveſtris, purpureo flore, ſemine rotundo vario. J. B. 2. 291. *Wild Lupine, with a purple flower and a round variegated ſeed, commonly called the leſſer blue Lupine.*
2. Lupinus (*Anguſtifolius*) calycibus verticillatis appendiculatis, labio ſuperiore bipartito, inferiore integro. Lin. Sp. Plant. 721. *Lupine with empalements having alternate appendages, whoſe upper lip is divided into two, and the under one entire.* Lupinus anguſtifolius cœruleus elatior. Raii Hiſt. 908. *Narrow-leaved taller blue Lupine.*
3. Lupinus (*Luteus*) calycibus verticillatis appendiculatis, labio ſuperiore bipartito, inferiore tridentato. Hort. Cliff. 499. *Lupine with empalements growing in whorls, having appendages to them, whoſe upper lips are cut into two parts, and the under one into three.* Lupinus ſylveſtris, flore luteo. C. B. P. 348. *The common yellow Lupine.*

4. Lupinus (*Hirſutis*) calycibus verticillatis appendiculatis, labio ſuperiore inferioreque integris. Hort. Cliff. 499. *Lupine with whorl-ſhaped empalements having appendages, and the upper and under lip entire.* Lupinus peregrinus major, vel villoſus, cœruleus, major. C. B. P. *Foreign, greater, hairy Lupine, with a large blue flower, commonly called the great blue Lupine.*

5. Lupinus (*Albus*) calycibus alternis inappendiculatis, labio ſuperiore integro, inferiore tridentato. Hort. Cliff. 499. *Lupine with alternate empalements having no appendages, and the upper lip entire, but the under cut into three parts.* Lupinus ſativus, flore albo. C. B. P. 347. *Garden or manured Lupine, with a white flower.*

6. Lupinus (*Perennis*) calycibus alternis inappendiculatis, labio ſuperiore emarginato, inferiore integro. Lin. Sp. Plant. 721. *Lupine with alternate empalements having no appendages, the upper lip indented, and the under entire.* Lupinus cœruleus, minor, perennis, Virginianus, repens. Mor. Hiſt. 2. p. 87. *Smaller perennial, creeping, blue Lupine of Virginia.*

The firſt ſort grows naturally among the Corn in the ſouth of France and Italy, and in great abundance in Sicily. This is an annual plant, which riſes with a firm, ſtrait, channelled ſtalk near three feet high, divided toward the top into ſeveral branches, which are garniſhed with hand-ſhaped leaves, compoſed of five, ſix, or ſeven oblong lobes, which join in one center at their baſe, and are hairy. The flowers are produced in ſpikes at the end of the branches, ſtanding half round the ſtalk in ſort of whorls; they are of a light blue colour, ſhaped like thoſe of Peas, and are ſucceeded by ſtrait taper pods with one cell, incloſing a row of roundiſh ſeeds. This ſort flowers in June and July, and the ſeeds ripen in the autumn.

It is propagated in the borders of the pleaſure-garden for ornament, by ſowing the ſeeds in April, in the places where they are to remain; and when the plants come up they ſhould be thinned where they are too cloſe, and kept clean from weeds, which is all the culture they require.

The ſecond ſort has much the appearance of the firſt, but the ſtalks riſe higher; the leaves have more lobes, and ſtand upon longer foot-ſtalks; the lobes are blunt-pointed, and the ſeeds are variegated. This requires the ſame culture as the firſt, and flowers at the ſame time.

The third ſort is the common yellow Lupine, which has been long cultivated in the Engliſh gardens for the ſweetneſs of its flowers. This grows naturally in Sicily; it riſes about a foot high, with a branching ſtalk garniſhed with hand-ſhaped leaves, compoſed of nine narrow hairy lobes, which join at their baſe to the foot-ſtalks; theſe are four or five inches long. The flowers are yellow, and are produced in looſe ſpikes at the end of the branches, ſtanding in whorls round the ſtalks, with ſpaces between them, terminated by three or four flowers, ſitting cloſe at the top; theſe are ſucceeded by flattiſh hairy pods about two inches long, ſtanding erect, incloſing four or five roundiſh ſeeds, a little compreſſed on their ſide, of a yellowiſh white, variegated with dark ſpots. This ſort flowers at the ſame time as the former, but to have a ſucceſſion of the flowers, the ſeeds are ſown at different times, viz. in April, May, and June; but thoſe only, which are firſt ſown, will ripen their ſeeds. It may be cultivated in the ſame manner as the two former, and is equally hardy.

The fourth ſort is ſuppoſed to be a native of India, but has been many years in the Engliſh gardens. It is an annual plant, which riſes with a ſtrong, firm, channelled ſtalk from three to four feet high, covered with a ſoft browniſh down, dividing upward into ſeveral ſtrong branches, garniſhed with hand-ſhaped leaves, compoſed of nine, ten, or eleven wedge-ſhaped hairy lobes, which are narrow at their baſe where they join the foot-ſtalk, but enlarge upward, and are rounded at the top where they are broadeſt; the foot-ſtalks of the leaves are three or four inches long. The flowers are placed in whorls round the ſtalks above each other, forming a looſe ſpike, which proceeds from the end of the branches; they are large, and of a beautiful blue colour, but have no ſcent. Theſe appear in July, and the ſeeds ripen in the autumn. The pods of this ſort are large, almoſt an inch broad, and three inches long, incloſing three large roundiſh ſeeds compreſſed on their ſides, very rough, and of a purpliſh brown colour. There is a variety of this with fleſh-coloured flowers, which is commonly called the Roſe Lupine; it differs from the blue only in the colour of the flower, but this difference is permanent, for neither of the ſorts vary.

This is generally late in ripening the ſeeds, ſo that unleſs the autumn proves warm and dry, they do not ripen; therefore the beſt way to have good ſeeds, is to ſow them in September cloſe to a warm wall on dry ground, where they will live through our ordinary winters; and theſe plants will flower early the following ſummer, ſo there will be time for the ſeeds to ripen before the rains fall in the autumn, which frequently cauſes the ſeeds to rot which are not ripe. If a few of the ſeeds of both theſe varieties are ſown in ſmall pots the beginning of September, and when the froſts begin, the pots are removed into a common hot-bed frame, where they may be protected from hard froſt, but enjoy the free air in mild weather, the plants may be thus ſecured in winter; and in the ſpring they may be ſhaken out of the pots, preſerving the earth to their roots, and planted in a warm border, where they will flower early, and produce very good ſeeds.

The fifth ſort grows naturally in the Levant, but is cultivated in ſome parts of Italy, as other pulſe, for food. This hath a thick upright ſtalk about two feet high, which divides toward the top into ſeveral ſmaller hairy branches, garniſhed with hand-ſhaped leaves, compoſed of ſeven or eight narrow oblong lobes, which are hairy, and join at their baſe, of a dark grayiſh colour, and have a ſilvery down. The flowers are produced in looſe ſpikes at the end of the branches; they are white, and ſit cloſe to the ſtalk; theſe are ſucceeded by hairy ſtrait pods about three inches long, a little compreſſed on the ſides, containing five or ſix flattiſh ſeeds which are white, having a little cavity like a navel, in that part which is fixed to the pod. This ſort flowers in July, and the ſeeds ripen in the autumn. It is an annual plant, which is cultivated for ornament in the pleaſure-garden. The ſeeds muſt be ſown in the places where the plants are to remain, and may be treated in the ſame way as the firſt ſort.

The ſixth ſort grows naturally in Virginia, and other of the northern parts of America. This hath a perennial creeping root, from which ariſe ſeveral erect channelled ſtalks a foot and a half high, ſending out two or three ſmall ſide branches, garniſhed with hand-ſhaped leaves, compoſed of ten or eleven narrow ſpear-ſhaped lobes, which join at their baſe, ſtanding upon very long foot-ſtalks, having a few hairs on their edges. The flowers grow in long looſe ſpikes, which terminate the ſtalks, and are placed without order on each ſide; they are of a pale blue colour, having ſhort foot-ſtalks. Theſe appear in June, and the ſeeds ripen in Auguſt, which are ſoon ſcattered if they are not gathered when ripe; for after a little moiſture, the ſun cauſes the pods to open with an elaſticity, and caſt out the ſeeds to a diſtance all round. This ſort is propagated by ſeeds as the former, which ſhould be ſown where the plants are to remain; for although the root is perennial, yet it runs ſo deep into the ground as that it cannot be taken up entire; and if the root is cut or broken, the plant ſeldom thrives well after. I have traced ſome of the roots of this plant, which have been three feet deep in the ground in one year from ſeed, and ſpread out as far on every ſide, ſo that they muſt have room, therefore the young plants ſhould not be left nearer than three feet aſunder. If this plant is in a light dry ſoil, the roots will continue ſeveral years, and produce many ſpikes of flowers; and although the uſual ſeaſon of flowering is in June and

July, yet when rain happens to fall in Auguſt, there are frequently freſh ſtalks ariſe from the roots, which flower the end of September, or beginning of October.

The ſeeds of the fifth ſort are uſed in medicine; they have a bitter taſte, ſo open, digeſt, diſſolve, and cleanſe; and if they are ſteeped in water for ſome days, till they have loſt their bitterneſs, they may be eaten out of neceſſity, but they are ſuppoſed to breed groſs humours, and are hard of digeſtion. Some women uſe the flower of the ſeed mixed with the juice of Lemons, and a little Alumen ſaccharinum, made into the form of ſoft ointment, to make the face ſmooth, and look more amiable.

The ſmall blue Lupine is frequently ſown in Italy, to dreſs and manure the ground, eſpecially that which is intended for vineyards; where, if they have time, the ground is ſown with Lupines, which grow till they begin to flower; then they cut them down and plough them into the ground, where the ſtalks rot with the winter's rain; but it is doubtful whether this is any real benefit to the ground, for there are few plants which draw and impoveriſh the ground ſo much as Lupines; therefore the dreſſing they yield, is ſcarce an equivalent for what they have drawn from the ground: but when there is not time for this operation, they parboil the ſeeds to prevent their growing, and ſow them upon the ground before it is ploughed, allowing ſixteen buſhels to an acre of land; and this dreſſing is preferable to the former.

All the ſorts of Lupines make a pretty appearance when they are in flower, but the yellow ſort is preferred for its ſweetneſs, though the flowers of this are of ſhort duration, eſpecially in warm weather; therefore the ſeeds of this ſhould be ſown at ſeveral times, that there may be a ſucceſſion of flowers through the ſeaſon, for they will continue flowering till they are ſtopped by hard froſt; and thoſe which come in the autumn to flower, will continue in beauty a longer time than the early ones. If ſome of the ſeeds are ſown in the autumn on a warm border, the plants will often live through the winter, and flower early in the ſpring.

LUPULUS. Tourn. Inſt. R. H. 535. tab. 309. Humulus. Lin. Gen. Plant. 989. [This plant takes its name of Lupus, *Lat.* a wolf, becauſe the antients had a notion, that wolves were wont to hide themſelves under this plant.] The Hop; in French, *Houblon.*

The CHARACTERS are,

The male and female flowers are upon different plants. The empalement of the male flower is compoſed of five ſmall, concave, obtuſe leaves; it hath no petal, but has five ſhort hairy ſtamina, terminated by oblong ſummits. The female flowers have a general, four-pointed, acute peranthium, and a ſeparate oval one of four leaves, including eight flowers; each of theſe have an empalement of one leaf, which is cloſed at the baſe. Theſe have neither petal or ſtamina, but a ſmall germen ſituated in the center, ſupporting two awl-ſhaped ſtyles, crowned by acute, reflexed, ſpreading ſtigmas. The germen afterward turns to a roundiſh ſeed covered with a thin ſkin, incloſed in the baſe of the empalement.

This genus of plants is ranged in the fifth ſection of Linnæus's twenty-ſecond claſs, intitled Diœcia Pentandria, which includes thoſe plants whoſe male and female flowers are upon different plants, and the male flowers have five ſtamina.

We have but one SPECIES of this genus, viz.

LUPULUS (*Humilus*) mas & femina. C. B. P. 298. *Male and female Hop.*

The male Hop grows wild by the ſide of hedges and upon banks, in many parts of England: the young ſhoots of theſe plants are often gathered in the ſpring by the poor people, and boiled as an eſculent herb; but theſe muſt be taken very young, otherwiſe they are tough and ſtringy; it is eaſily diſtinguiſhed by the flowers, which are ſmall, and hang in long looſe bunches from the ſide of the ſtalks, abounding with farina on their ſummits; theſe have no Hops ſucceeding to the flowers.

The female Hop is the ſort which is cultivated for uſe; of this ſort, the people who cultivate them reckon three different varieties: as firſt, the long and ſquare Garlick Hop, the long white Hop, and the oval Hop, all which are indifferently cultivated in England, but of the male Hop there is no different varieties.

There being the greateſt plantation of Hops in Kent that are in any county of England, it is very probable, that their method of planting and ordering them ſhould be the beſt.

As for the choice of their Hop-grounds, they eſteem the richeſt and ſtrongeſt grounds as the moſt proper; they chuſe a warm dry ſoil, that has a good depth of hazel mould; and if it be rocky within two or three feet of the ſurface, the Hops will proſper well; but they will by no means thrive on a ſtiff clay, or ſpongy wet land.

If it may be, chuſe a piece of meadow or lay ground to plant Hops on, ſuch as has not been tilled or ſown with other crops for many years, or an old decayed orchard; for land that is worn out by long bearing of Corn, will require abundance of dung to bring it into any tolerable condition to bear a crop of Hops.

The Kentiſh planters accounting new land beſt for Hops, they plant their Hop-gardens with Apple-trees at a large diſtance, and with Cherry-trees between; and when the land hath done its beſt for Hops, which they reckon it will in about ten years, the trees may begin to bear. The Cherry-trees laſt about thirty years, and by that time the Apple-trees are large, they cut down the Cherry-trees.

The Eſſex planters account a moory land the propereſt for Hops, though there are ſeveral other ſorts of ſoil that are eſteemed very good.

Some account that land which has a roſſelly top, and a brick earth bottom, the beſt; a true roſſel or light ſand, is what they generally plant in, whether it be white or black.

Moory land is of different ſorts, ſome being ſtrong and heavy, ſo as to crack in ſummer; and ſome ſo light, that in dry ſeaſons it will blow away with the wind; and ſome are of a middle conſiſtence, being compoſed of both.

Theſe moors for goodneſs and value, are according to the nature and goodneſs of the ſoil that is underneath them; which being flung up upon the ſurface, will make a very good mixture, it being beſt to fling the under ſoil downward for Hops, becauſe they naturally root downwards, ſometims four or five yards deep, and therefore the deepeſt and richeſt ſoil is beſt for them.

Few are acquainted with the value of moors, becauſe they do not ſearch into the bottom of them, by reaſon of the expenſiveneſs of doing it, and the difficulty of carrying off the water.

If the land be moiſt, it ought to be laid up in high ridges, and to be well drained, and the drains kept clear and open, eſpecially in winter, that the water do not rot or too much chill the roots.

If the land be ſour or cold, it will be very much helped by burning it; and if the haulm and ſtrings of the Hops be burnt every year, and ſome of the paring or ſides of the garden or other earth be laid on them as they burn, and then more haulm be laid over that, and ſo continued layer upon layer, it will make an excellent compoſt to make the hills with.

As to the ſituation of a Hop-ground, one that inclines to the ſouth or weſt is the moſt eligible; but if it be expoſed to the north-eaſt or ſouth-weſt winds, there ſhould be a center of ſome trees at a diſtance; becauſe the north-eaſt are apt to nip the tender ſhoots in the ſpring, and the ſouth-weſt frequently break and blow the poles at the latter end of the ſummer, and very much endanger the Hops.

Hops require to be planted in an open ſituation, that the air may freely paſs round and between them to dry up and diſſipate the moiſture, whereby they will not be ſo ſubject to fire blaſts, which often deſtroy the middles of large plantations, while the outſides remain unhurt.

As for the preparation of the ground for planting, it ſhould, the winter before, be ploughed and harrowed even; and then lay upon it in heaps a good quantity of freſh rich earth, or well rotted dung and earth mixed together, ſufficient to put half a buſhel in every hole to plant the Hops in, unleſs the natural ground be very freſh and good.

Then lay a line acroſs it from the hedge, in which knots have been tied, at the diſtance you deſign your Hop-hills to be at, about eight or nine feet diſtance the whole length of the ground, and place a ſharp pointed ſtick at every knot; then lay aſide the line, and with two forked ſticks of about eight or nine feet long, you may from the firſt row ſet out the whole ground, by applying the two forks to two of the ſticks which were firſt ſet up, and placing another row at the ends, where the forked ſticks meet triangular-wiſe; then you ſhould dig a hole at every ſtick about a foot and a half wide, and fill it full of the good earth you brought in.

If you plough the ground with horſes between the hills, it will be beſt to plant them in ſquares chequer-wiſe; but the quincunx form is the moſt beautiful, and it will alſo be better for the Hop; but if the ground is intended to be cultivated by the breaſt-plough, it will be beſt to plant them in ſquares; but which way ſoever you make uſe of, a ſtake ſhould be ſtuck down at all the places where the hills are to be made.

Perſons ought to be very curious in the choice of the plants and ſets, as to the kind of the Hop; for if the Hop-garden be planted with a mixture of two or three ſorts of Hops that ripen at different times, it will cauſe a great deal of trouble, and be a great detriment to the owner.

The two beſt ſorts are the white and the gray bind; the latter is a large ſquare Hop, more hardy, and is the more plentiful bearer, but ripens later than the former.

There is alſo another ſort of the white bind, which ripens in a week or ten days before the common; but this is tenderer, and a leſs plentiful bearer, but it has this advantage, it comes firſt to market.

But if three grounds, or three diſtant parts of one ground, be planted with theſe three ſorts, there will be this conveniency, that they may be picked ſucceſſively as they become ripe.

The ſets ought to be procured out of grounds that are entirely of the ſame ſort you would have, they ſhould be five or ſix inches long, with three or more joints or buds on them, all the old bind and hollow part of the ſet being cut off.

If there be a ſort of Hop you value, and would increaſe plants and ſets from, the ſuperfluous binds may be laid down when the Hops are tied, cutting off the tops, and burying them in the hill; or when the Hops are dreſſed, all the cuttings may be ſaved, and laid in rows in a bed of good earth; for almoſt every part will grow, and become a good ſet the next ſpring.

Some have tried to raiſe a Hop-ground by ſowing ſeeds, but that turns to no account, becauſe that way is not only tedious, but the Hops ſo produced are commonly of different kinds, and many of them wild and barren.

As to the ſeaſons of planting Hops, the Kentiſh planters beſt approve the months of October and March, both which ſucceed very well; but the common ſets are not to be had in October, unleſs from ſome ground that is to be digged up and deſtroyed; and likewiſe there is ſome danger that the ſets may be rotted, if the winter prove very wet; but the moſt uſual time of procuring them is in March, when the Hops are cut and dreſſed.

As to the manner of planting the ſets, you ſhould put two or three good ſets in every hole with a ſetting ſtick, at about four inches diſtance, placing them ſloping; they muſt ſtand even with the ſurface of the ground; let them be preſſed cloſe with the hand, and covered with fine earth, and a ſtick ſhould be placed on each ſide the hill to ſecure it.

The ground being thus planted, all that is to be done more that ſummer, is to keep the hills clear from weeds, and to horſe-hoe the ground about the month of May, gathering up the ſtones, if more are turned up by ploughing, and to raiſe a ſmall hill round about the plants; and in June you muſt twiſt the young binds or branches together in a bunch or knot, for if they are tied up to ſmall poles the firſt year, in order to have a few Hops from them, it will not countervail the weakening the plants.

A mixture of compoſt or dung being prepared for your Hop-ground, the beſt time for laying it on, if the weather prove dry, is about Michaelmas, that the wheels of the dung-cart may not injure the Hops, nor furrow the ground: if this be not done then, you muſt be obliged to wait till the froſt has hardened the ground, ſo that it will bear the dung-cart; and this is alſo the time to carry on your new poles, to recruit thoſe that are decayed, and to be caſt out every year.

If you have good ſtore of dung, the beſt way will be to ſpread it in the alleys all over the ground, and to dig or plough it in the winter following. The quantity they will require, will be forty loads to an acre, reckoning about thirty buſhels to the load.

If you have not dung enough to cover all the ground in one year, you may lay it on one part one year, and on the reſt in another, or a third; for there is no occaſion to dung the ground after this manner, oftener than once in two or three years.

Thoſe who have but a ſmall quantity of dung, uſually content themſelves with laying on about twenty loads upon an acre every year; this they lay only on the hills, either about November, or in the ſpring; which laſt ſome account the beſt time, when the Hops are dreſſed, to cover them after they are cut; but if it be done at this time, the compoſt or dung ought to be very well rotted and fine.

As to the dreſſing of the Hops, when the Hop-ground is dug or ploughed in January or February, the earth about the hills, and very near them, ought to be taken away with a ſpade, that you may come the more conveniently at the ſtock to cut it.

About the end of February, if the Hops were planted the ſpring before, or if the ground be weak, they ought to be dreſſed in dry weather; but elſe, if the ground be ſtrong and in perfection, the middle of March will be a good time; and the latter end of March, if it be apt to produce over rank binds, or the beginning of April, may be ſoon enough.

Then having with an iron picker cleared away all the earth out of the hills, ſo as to make the ſtock bear to the principal roots, with a ſharp knife you muſt cut off all the ſhoots which grew up with the binds the laſt year; and alſo all the young ſuckers, that none be left to run in the alley and weaken the hill. It will be proper to cut one part of the ſtock lower than the other, and alſo to cut that part low, that was left higheſt the preceding year. By purſuing this method, you may expect to have ſtronger buds, and alſo keep the hill in good order.

In dreſſing thoſe Hops that have been planted the year before, you ought to cut off both the dead tops, and the young ſuckers which have ſprung up from the ſets, and alſo to cover the ſtocks with fine earth a finger's length in thickneſs.

About the middle of April the Hops are to be polled, when the ſhoots begin to ſprout up; the poles muſt be ſet to the hills deep into the ground, with a ſquare iron pitcher or crow, that they may the better endure the wind; three poles are ſufficient for one hill. Theſe ſhould be placed as near the hills as may be, with their bending tops turned outwards from the hill, to prevent the binds from entangling; and a ſpace between two poles ought to be left open to the ſouth, to admit the ſun beams.

The poles ought to be in length ſixteen or twenty feet, more or leſs, according as the ground is in ſtrength; and great care is to be taken not to over-pole a young or weak ground, for that will draw the ſtock too much, and weaken it. If a ground be over-polled, you are not to expect a good crop from it; for the branches which bear the Hops will grow very little, till the binds have over-reached the poles, which they cannot do when the poles are too long. Two ſmall poles are ſufficient for a ground that is young.

If you wait till the ſprouts or young binds are grown to the length of a foot, you will be able to make a better judgement where to place the largeſt poles; but if you ſtay till they are ſo long as to fall into the alleys, it will be injurious to them, becauſe they will entangle one with another, and will not claſp about the pole ſo readily.

Maple or Aſpen poles are accounted the beſt for Hops, on which they are thought to proſper beſt, becauſe of their warmth; or elſe, becauſe the climbing of the Hop is furthered by means of the roughneſs of the bark. But for laſtingneſs, Aſhen or Willow poles are preferable; but Cheſtnut poles are the moſt durable of all.

If, after the Hops are grown up, you find any of them have been under-polled, taller poles may be placed near thoſe that are too ſhort, to receive the binds from them.

As to the tying of Hops, the buds that do not claſp of themſelves to the neareſt pole when they are grown to three or four feet high, muſt be guided to it by the hand, turning them to the ſun, whoſe courſe they will always follow. They muſt be bound with withered Ruſhes, but not ſo cloſe as to hinder them from climbing up the pole.

This you muſt continue to do till all the poles are furniſhed with binds, of which two or three are enough for a pole; and all the ſprouts and binds that you have no occaſion for, are to be plucked up; but if the ground be young, then none of theſe uſeleſs binds ſhould be plucked up, but ſhould be wrapt up together in the middle of the hill.

When the binds are grown beyond the reach of your hands, if they forſake the poles, you ſhould make uſe of a ſtand ladder in tying them up.

Some adviſe, that if the binds be very ſtrong, and overgrow the poles very much, you ſtrike off their heads with a long ſwitch, to increaſe their branching below.

Towards the latter end of May, when you have made an end of tying them, the ground muſt have the ſummer ploughing or digging, which is done by caſting up with the ſpade ſome fine earth into every hill, and a month after it muſt be again repeated, and the hills made up to a convenient bigneſs.

It is not at all to be doubted, but that a thorough watering would be of very great advantage to Hops in a hot dry ſummer; but it is ſo much charge and trouble to do this, that unleſs you have a ſtream at hand to flow the ground, it is ſcarce practicable.

When the Hops blow, you ſhould obſerve if there be any wild barren hills among them, and mark them, by driving a ſharpened ſtick into every ſuch hill, that they may be digged up and replanted.

Hops as well as other vegetables, are liable to diſtempers and diſaſters, and among the reſt, to the fen. The Rev. Dr. Hales, in his excellent Treatiſe of Vegetable Statics, treating of Hops, gives us the following account of the ſtate of Hops in Kent in the year 1725, that he received from Mr. Auſten of Canterbury, which is as follows:

In mid April not half the ſhoots appeared above ground, ſo that the planters knew not how to pole them to the beſt advantage.

This defect of the ſhoot, upon opening the hills, was found to be owing to the multitude and variety of vermin that lay preying upon the roots; the increaſe of which, was imputed to the long and almoſt uninterrupted ſeries of dry weather for three months before.

Towards the end of April many of the Hop-vines were infeſted with flies.

About the 20th of May there was a very unequal appearance, ſome Vines being run ſeven feet, others not above three or four; ſome juſt tied to the poles, and ſome not viſible; and this diſproportionate inequality in their ſize, continued through the whole time of their growth.

The flies now appeared upon the leaves of the forwardeſt Vines, but not in ſuch numbers here, as they did in moſt other places. About the middle of June the flies increaſed, yet not ſo as to endanger the crop; but in diſtant plantations they were exceedingly multiplied, ſo as to ſwarm towards the end of the month.

June the 27th ſome ſpecks of fen appeared. From this day to the 9th of July was very dry weather. At this time, when it was ſaid, that the Hops in moſt parts of the kingdom looked black and ſickly, and ſeemed paſt recovery, ours held it out pretty well, in the opinion of the moſt ſkilful planters.

The great leaves were indeed diſcoloured, and a little withered, and the fen was ſomewhat increaſed. From the 9th of July to the 23d, the fen increaſed a great deal; but the flies and lice decreaſed, it raining much daily. In a week more the fen, which ſeemed to be almoſt at a ſtand, was conſiderably increaſed, eſpecially in thoſe grounds where it firſt appeared.

About the middle of Auguſt the Vines had done growing both in ſtem and branch, and the forwardeſt began to be in the Hop, the reſt in bloom; the fen continued ſpreading where it was not before perceived, and not only the leaves, but many of the burs were alſo tainted with it.

About the 20th of Auguſt ſome of the Hops were infected with the fen, and whole branches corrupted by it. Half the plantations had pretty well eſcaped hitherto, and from this time the fen increaſed but little; but ſeveral days wind and rain the following week ſo diſtorted them, that many of them began to dwindle, and at laſt came to nothing; and of thoſe that then remained in bloom, ſome never turned to Hops; and of the reſt which did, many of them were ſo ſmall, that they very little exceeded the bigneſs of a good thriving bur.

We did not begin to pick till the 8th of September, which is eighteen days later than we began the year before; the crop was little above two hundred on an acre round, and not good. The beſt Hops ſold this year at Way-hill, for 16 l. the hundred.

The Rev. Dr. Hales, in his aforeſaid Treatiſe, gives us an account of the following experiment that he made on Hop-vines. He tells us, that in July he cut off two thriving Hop-vines near the ground, in a thick ſhady part of the garden, the pole ſtill ſtanding; he ſtripped the leaves off from one of theſe Vines, and ſet their ſtems in known quantities of water in little bottles; that with leaves imbibed in a twelve hours day four ounces, and that without leaves three-fourths of an ounce.

He took another Hop-pole with its Vines on it, and carried it out of the Hop-ground into a free and open expoſure; theſe imbibed and perſpired as much more as the former in the Hop-ground, which is, doubtleſs, the reaſon why the Hop-vines on the outſides of plantations, where they are moſt expoſed to the air, are ſhort and poor, in compariſon of thoſe in the middle of the ground, viz. becauſe being much dried, their fibres harden ſooner, and therefore they cannot grow ſo kindly as thoſe in the middle of the ground, which, by ſhade, are always kept moiſter, and more ductile.

The ſame curious author proceeds as followeth: Now there being 1000 hills in an acre of Hop-ground, and each hill having three poles, and each pole three Vines, the number of Vines will be 9000, each of which perſpiring four ounces, the ſum of all the ounces perſpired by an acre in twelve hours day will be 36000 ounces = 15750000 grains = 62007 cube inches, or 220 gallons, which divided by 6272640, the number of ſquare inches in an acre, it will be found, that the quantity of liquor perſpired by all the Hop-vines will be equal to an area of liquor as broad as an acre, and

$\frac{1}{161}$ part of an inch deep, beſides what evaporated from the earth.

And this quantity of moiſture, in a kindly ſtate of the air, if daily carrried off, is a ſufficient quantity to keep the Hops in a healthy ſtate; but in a rainy moiſt ſtate of air, without a due mixture of dry weather, too much moiſture hovers about the Hops, ſo as to hinder, in ſome meaſure, the kindly perſpiration of the leaves, whereby the ſtagnating ſap corrupts, and breeds mouldy fen, which often ſpoils vaſt quantities of flouriſhing Hop-grounds.

This was the caſe in the year 1723, when for ten or fourteen days almoſt continual rains fell, about the latter half of July, after four months dry weather, upon which the moſt flouriſhing and promiſing Hops were all infected with mould, or fen, in their leaves and fruit, while the then poor and unpromiſing Hops eſcaped, and produced plenty, becauſe they, being ſmall, did not perſpire ſo great a quantity as others, nor did they confine the perſpired vapour, ſo much as the large thriving Vines did in their ſhady thickets.

This rain on the then warm earth, made the Graſs ſhoot out as faſt as if it were in a hot-bed, and the Apples grew ſo precipitately, that they were of a flaſhy conſtitution, ſo as to rot more remarkably than had ever been remembered.

The planters obſerve, That when a mould, or fen, has once ſeized any part of the ground, it ſoon runs over the whole, and that the Graſs, and other herbs under the Hops, are infected with it, probably, becauſe the ſmall ſeeds of this quick-growing mould, which ſoon come to maturity, are blown over the whole ground; which ſpreading of the ſeed may be the reaſon why ſome grounds are infected with fen for ſeveral years ſucceſſively, viz. from the ſeeds of the laſt year's fen. Might it not then be adviſed to burn the fenny Hop-vines, as ſoon as the Hops are picked, in hopes thereby to deſtroy ſome of the ſeed of the mould?

Mr. Auſten, of Canterbury, obſerves fen to be more fatal to thoſe grounds that are low and ſheltered, than to the high and open grounds, to thoſe that are ſhelving to the north, than to thoſe ſhelving to the ſouth; to the middle of grounds than to the outſides; to the dry and gentle grounds, than to the moiſt and ſtiff grounds.

This was very apparent throughout the plantations where the land had the ſame workmanſhip and help beſtowed upon it, and was wrought at the ſame time. But if in either of theſe caſes there was a difference, it had a different effect, and the low and gentle grounds, that lay neglected, were then ſeen leſs diſtempered than the open and moiſt, which were carefully managed and looked after.

The honey dews are obſerved to come about the 11th of June, which, by the middle of July, turn the leaves black, and make them ſtink.

The ſaid Dr. Hales relates, That in the month of July (the ſeaſon for fire-blaſts, as the planters call them) he has ſeen the Vines in the middle of the Hop-ground ſcorched up almoſt from one end of a large ground to the other, when a hot gleam of ſun-ſhine has come immediately after a ſhower of rain, at which time vapours are all ſeen with the naked eye, but eſpecially with reflecting teleſcopes, to aſcend ſo plentifully as to make a clear and diſtinct object become immediately very dim and tremulous; nor was there any dry gravelly vein in the ground along the courſe of this ſcorch; it was therefore, probably, owing to the much greater quantity of ſcorching vapours in the middle, than the outſides of the ground, and that being a denſer medium, it was much hotter than a more rare medium.

And, perhaps, the great volume of aſcending vapours might make the ſun-beams converge a little towards the middle of the ground, that being a denſer medium, and thereby increaſe the heat conſiderably; for he obſerved, That the courſe of the ſcorched Hops was in lines at right angles to the ſun-beams about eleven o'clock, at which time the hot gleam was. The Hop-ground was in a valley which ran from ſouth-weſt to north-eaſt, and to the beſt of his remembrance, there was but little wind, and that in the courſe of the ſcorch; but had there been ſome other gentle wind, either north or ſouth, it is not improbable but that the north wind gently blowing the volume of riſing wreak on the ſouth ſide of the ground, that ſide might have been moſt ſcorched, and ſo vice verſa.

As to particular fire-blaſts, which ſcorch here and there a few Hop-vines, or one or two branches of a tree, without damaging the next adjoining, what aſtronomers obſerve, may hint to us no very improbable cauſe of it, viz. They frequently obſerve (eſpecially with reflecting teleſcopes) ſmall ſeparate portions of pellucid vapours floating in the air, which, though not viſible to the naked eye, are yet conſiderably denſer than the circumambient air; and vapours of ſuch a degree of denſity may very probably either acquire ſuch a ſcalding heat from the ſun as will ſcorch what plants they touch, eſpecially the more tender.

(An effect which the gardeners about London have too often found to their coſt, when they have incautiouſly put bell-glaſſes over their Cauliflowers early in a froſty morning, before the dew was evaporated off them; which dew, being raiſed by the ſun's warmth, and confined within the glaſs, did there form a denſe, tranſparent, ſcalding vapour, which burned and killed the plants:)

Or, perhaps, the upper or lower ſurface of theſe tranſparent, ſeparate, flying volumes of vapours, may, among the many forms they revolve into, ſometimes approach ſo near to an hemiſphere, or hemicylinder, as thereby to make the ſun-beams converge, ſo as often to ſcorch the more tender plants they ſhall fall on, and ſometimes alſo parts of the more hardy plants and trees, in proportion to the greater or leſſer convergency of the ſun's rays.

The learned Boerhaave, in his Theory of Chymiſtry, p. 245, Shaw's edition, obſerves, That thoſe white clouds which appear in ſummer time, are, as it were, ſo many mirrours, and occaſion exceſſive heat. Theſe cloudy mirrours are ſometimes round, ſometimes concave, polygonous, &c. When the face of heaven is covered with ſuch white clouds, the ſun ſhining among them, muſt, of neceſſity, produce a vehement heat, ſince many of his rays, which would otherwiſe, perhaps, never touch our earth, are hereby reflected to us. Thus, if the ſun be on one ſide, and the clouds on the oppoſite one, they will be perfect burning-glaſſes, and hence the phænomena of thunder.

I have ſometimes (continues he) obſerved a kind of hollow clouds full of hail and ſnow, during the continuance of which the heat was extreme, ſince, by ſuch condenſation, they were enabled to reflect more ſtrongly. After this came a ſharp cold, and then the clouds diſcharged their hail in great quantity, to which ſucceeded a moderate warmth. Frozen concave clouds, therefore, by their great reflexions, produce a vigorous heat, and the ſame, when reſolved, exceſſive cold.

From which the Rev. Dr. Hales obſerves as follows: Hence we ſee, that blaſts may be occaſioned by the reflexions of the clouds, as well as by the above-mentioned refraction of denſe tranſparent vapours.

About the middle of July Hops begin to blow, and will be ready to gather about Bartholomew-tide. A judgment may be made of their ripeneſs, by their ſtrong ſcent, their hardneſs, and the browniſh colour of their ſeed.

When by theſe tokens they appear to be ripe, they muſt be picked with all the expedition poſſible; for if at this time a ſtorm of wind ſhould come, it would do them great damage, by breaking the branches, and bruiſing and diſcolouring the Hops; and it is very well known, that Hops, being picked green and bright, will ſell for a third part more than thoſe which are diſcoloured and brown.

The moſt convenient way of picking them is into a long ſquare frame of wood, called a bin, with a cloth hanging on tenter-hooks within it, to receive the Hops as they are picked.

The frame is compoſed of four pieces of wood joined together, ſupported by four legs, with a prop at each end to bear up another long piece of wood, placed at a convenient height over the middle of the bin; this ſerves to lay the poles upon which are to be picked.

This bin is commonly eight feet long, and three feet broad; two poles may be laid on it at a time, and ſix or eight perſons may work at it, three or four on each ſide.

It will be beſt to begin to pick the Hops on the eaſt or north ſide of your ground, if you can do it conveniently; this will prevent the ſouth-weſt wind from breaking into the garden.

Having made choice of a plot of the ground containing eleven hills ſquare, place the bin upon the hill which is in the center, having five hills on each ſide; and when theſe hills are picked, remove the bin into another piece of ground of the ſame extent, and ſo proceed till the whole Hop-ground is finiſhed.

When the poles are drawn up to be picked, you muſt take great care not to cut the binds too near the hills, eſpecially when the Hops are green, becauſe it will make the ſap to flow exceſſively.

And if the poles do not come up without difficulty, they ſhould be raiſed by a piece of wood in the nature of a lever, having a forked piece of iron, with teeth on the inſide, faſtened within two feet of the end.

The Hops muſt be picked very clean, i. e. free from leaves and ſtalks, and, as there ſhall be occaſion, two or three times in a day the bin muſt be emptied into a Hop-bag made of coarſe linen cloth, and carried immediately to the oaſt, or kiln, in order to be dried; for if they ſhould be long in the bin, or bag, they will be apt to heat, and be diſcoloured.

If the weather be hot, there ſhould no more poles be drawn than can be picked in an hour, and they ſhould be gathered in fair weather, if it can be, and when the Hops are dry; this will ſave ſome expence in firing, and preſerve their colour better when they are dried.

The beſt method of drying Hops is with charcoal on an oaſt or kiln, covered with hair-cloth, of the ſame form and faſhion that is uſed for drying malt. There is no need to give any particular directions for the making it, ſince every carpenter, or bricklayer, in thoſe countries where Hops grow, or malt is made, knows how to build them.

The kiln ought to be ſquare, and may be of ten, twelve, fourteen, or ſixteen feet over at the top, where the Hops are laid, as your plantation requires, and your room will allow. There ought to be a due proportion between the height and breadth of the kiln, and the beguels of the ſteddle where the fire is kept, viz. if the kiln be twelve feet ſquare on the top, it ought to be nine feet high from the fire, and the ſteddle ought to be ſix feet and a half ſquare, and ſo proportionable in other dimenſions.

The Hops muſt be ſpread even upon the oaſt a foot thick or more, if the depth of the curb will allow it, but care is to be taken not to overload the oaſt, if the Hops be green or wet.

The oaſt ought to be firſt warmed with a fire before the Hops are laid on, and then an even ſteady fire muſt be kept under them; it muſt not be too fierce at firſt, leſt it ſcorch the Hops; nor muſt it be ſuffered to ſink or ſlacken, but rather be increaſed till the Hops be near dried, leſt the moiſture, or ſweat, which the fire has raiſed, fall back, or diſcolour them. When they have lain about nine hours, they muſt be turned, and in two or three hours more they may be taken off the oaſt. It may be known when they are well dried by the brittleneſs of the ſtalks, and the eaſy falling off of the Hop leaves.

The Dutch and Flemings have another method of drying their Hops: they make a ſquare kiln, or room, about eight or ten feet wide, built of brick or ſtone, having a door at one ſide, and a fire-place in the middle of the room, on the floor, about thirteen inches wide within, and thirteen inches high in length from the mouth of it, almoſt to the back part of the kiln, a paſſage being left juſt enough for a man to go round the end of it; this they call a horſe, ſuch as is commonly made in malt-kilns, the fire paſſing out at the holes at each ſide, and at the end of it.

The bed, or floor, on which the Hops lie to be dried, is placed about five feet high above; about that is a wall near four feet high, to keep the Hops from falling.

A window is made at one ſide of the upper bed, to ſhove off the dry Hops down into a room prepared to receive them. The beds are made of laths, or rails, ſawn very even, lying a quarter of an inch diſtant from one another, with a croſs beam in the middle, to ſupport them; the laths are let in even with the top of the beam, and this keeps them even in the places; this they call an oaſt.

The Hops are laid on this bed by baſkets full, without any oaſt-cloth, beginning at one end, and ſo going on till all is covered, half a yard thick, without treading them; then they even them with a rake, that they may lie of equal thickneſs.

This being done, they kindle the fire below, either of wood or charcoal, but the latter is accounted the better fuel for Hops; this fire is kept as much as may be at an equal or conſtant heat, and only at the mouth of the furnace, for the air will ſufficiently diſperſe it.

They do not ſtir them till they are thoroughly dried, i. e. till the top is as fully dried as the bottom; but if they find any place not to be ſo dry as the reſt, (which may be known by reaching over them with a ſtick or wand, and touching them in ſeveral places,) they obſerve where they do not rattle, and where they do; and where they do not rattle, they abate them there, and diſpoſe of them where the places were firſt dry.

They know when they are thoroughly dry, by the brittleneſs of the inner ſtalk, if it be ſhort when it is rubbed; which when they find, they take out the fire, and ſhove out the Hops at the window that is made for that purpoſe, into the room made to receive them, with a coal-rake made with a board at the end of a pole, and then go in at a door below, and ſweep up the Hops and ſeeds that fall through, and put them to the other Hops; then they lay another bed of green Hops, and renew the fire, and proceed as before.

This method is diſapproved by ſome, becauſe (they ſay) the Hops lying ſo thick, and not being turned, the under part of them muſt needs dry before the upper; and the fire paſſing through the whole bed to dry the uppermoſt, muſt neceſſarily over-dry, and much prejudice the greateſt part of the Hops, both in ſtrength and weight, beſides the unneceſſary expence of firing, which muſt be long continued to dry thoroughly ſo many together.

Therefore ſome have improved on this method, and adviſed to make the kiln much as is before directed as to the Dutch way.

Firſt to make a bed of flat ledges about an inch thick, and two or three inches broad, ſawn, and laid acroſs one another the flat way, chequerwiſe, at about three or four inches diſtance one from the other, the edges being ſo entered one into the other, that the floor may be even and ſmooth; this bed may be made to reſt on two or three joiſts, ſet edgewiſe, to ſupport it from ſinking.

This bed is to be covered with large double tin, ſoldered together at each joint, and the ledges muſt be ſo ordered, before they are laid, that the joints of the tin may always lie over the middle of the ledge, the bed being wholly covered over with tin: boards muſt be fitted about the edges of the kiln, to keep up the Hops, but one ſide muſt be made to remove, that the Hops may be ſhoved off as before.

On this bed, or floor of tin, the Hops may be turned without ſuch hazard or loſs, as upon the hair-cloth: and alſo it will require a leſs expence of fuel, and, beſides, any ſort of fuel will ſerve in this kiln, as well as charcoal, becauſe the ſmoke does not paſs through the Hops as it does the former ways; but then care is to be taken, that there be paſſages made for it at the ſeveral corners and ſides of the kiln.

It is found by experience, that the turning of Hops, though it be after the moſt eaſy and beſt manner, is not only an injury and waſte to the Hops, but alſo an expence of fuel and time, becauſe they require as much fuel, and as long a time, to dry a ſmall quantity, by turning them, as a large one.

Now, this may be prevented, by having a cover (to be let down and raiſed at pleaſure) to the upper bed whereon the Hops lie.

This cover may alſo be tinned, by nailing ſingle tin plates over the face of it, ſo that when the Hops begin to dry, and are ready to burn, i. e. when the greateſt part of their moiſture is evaporated, then the cover may be let down within a foot, or leſs, of the Hops (like a reverbatory) and will reflect the heat upon them, ſo that the top will ſoon be as dry as the lowermoſt, and every Hop be equally dried.

As ſoon as the Hops are taken off the kiln, lay them in a room for three weeks or a month to cool, give, and toughen; for if they are bagged immediately, they will powder, but if they lie a while (and the longer they lie the better, provided they be covered cloſe with blankets to ſecure them from the air,) they may be bagged with more ſafety, as not being liable to be broken to powder in treading, and this will make them bear treading the better, and the harder they are trodden, the better they will keep.

The common method of bagging is as follows; they have a hole made in an upper floor, either round or ſquare, large enough to receive a Hop-bag (which conſiſts of four ells and a half of ell-wide cloth, and alſo contains ordinarily two hundred and a half of Hops) they tie a handful of Hops in each lower corner of the bag, to ſerve as handles to it, and they faſten the mouth of the hole, ſo placed that the hoop may reſt upon the edges of the hole.

Then he that is to tread the Hops down into the bag, treads the Hops on every ſide, another perſon continually putting them in as he treads them, till the bag is full, which being well filled and trodden, they unrip the faſtening of the bag to the hoops, and let it down, and cloſe up the mouth of the bag, tying up a handful of Hops in each corner of the mouth, as was done in the lower part.

Hops being thus packed, if they have been well dried, and laid up in a dry place, they will keep good ſeveral years; but care muſt be taken, that they be neither deſtroyed nor ſpoiled by the mice making their neſts in them.

The crop of Hops being thus beſtowed, you are to provide for another, firſt by taking care of the poles againſt another year, which are beſt to be laid up in a ſhed, having firſt ſtripped off the haulm from them; but if you have not that conveniency, ſet up three poles in the form of a triangle, or ſix poles (as you pleaſe) wide at the bottom, and having ſet them into the ground, with an iron pitcher, and bound them together at top, ſet the reſt of your poles about them; and being thus diſpoſed, none but thoſe on the outſide will be ſubject to the injuries of the weather, for all the inner poles will be kept dry, unleſs at the top; whereas, if they were on the ground, they would receive more damage in a fortnight, than by their ſtanding all the reſt of the year.

In the winter time provide your ſoil and manure for the Hop-ground againſt the following ſpring.

If the dung be rotten, mix it with two or three parts of common earth, and let it incorporate together till you have occaſion to make uſe of it in making your Hop-hills; but if it be new dung, then let it be mixed as before, till the ſpring come twelvemonths, for new dung is very injurious to Hops.

Dung of all ſorts was formerly more commonly made uſe of than now it is, eſpecially when rotted, and turned to mould, and they who have no other manure muſt uſe it; which, if they do, cows or hogs dung, or human ordure mixed with mud, may be a proper compoſt, becauſe Hops delight moſt in a manure that is cool and moiſt.

Some recommend chalk, or lime, as the beſt manure, except in cold lands, and in ſuch, pigeons dung will do beſt; a little of which laid to a hill, and ſo mixed, that it may not be too hot in a place, is of great advantage.

LUTEOLA. See Reseda.

LYCHNIDEA. See Phlox.

LYCHNIS. Tourn. Inſt. R. H. 333. tab. 175. Lin. Gen. Plant. 517. [ſo called of Λύχνος, a candle, or light, becauſe the flowers of this plant imitate the flame or rays of light.] Campion.

The Characters are,

The flower has a permanent ſwollen empalement of one leaf, indented in five parts at the top. It hath five petals, whoſe tails are the length of the empalement, their upper part plain, broad, and frequently cleft in laminæ. It hath ten ſtamina which are longer than the empalement, alternately ranged, and faſtened to the tails of the petals, terminated by proſtrate ſummits. In the center is ſituated an almoſt oval germen, ſupporting five awl-ſhaped ſtyles, crowned by reflexed hairy ſtigmas. The empalement afterward becomes an oval capſule with one cell, opening with five valves, filled with roundiſh ſeeds.

This genus of plants is ranged in the fifth ſection of Linnæus's tenth claſs, intitled Decandria Pentagynia, which includes thoſe plants whoſe flowers have ten ſtamina and five ſtyles.

The Species are,

1. Lychnis (*Chalcedonica*) floribus faſciculatis faſtigiatis. Hort. Cliff. 174. *Campion with flowers gathered into a pyramid.* Lychnis hirſuta, flore coccineo, major. C. B. P. 203. *Greater hairy Campion with a ſcarlet flower.*
2. Lychnis (*Viſcaria*) petalis integris. Lin. Sp. Plant. 436. *Campion with entire petals.* Lychnis ſylveſtris viſcoſa, rubra, anguſtifolia. C. B. P. 205. *Wild viſcous Lychnis with a red flower and narrow leaves, commonly called the Single Catchfly.*
3. Lychnis (*Diœci*) floribus diœcis. Hort. Cliff. 171. *Campion with male and female flowers on different plants.* Lychnis ſylveſtris, ſive aquatica purpurea; ſimplex. C. B. P. 204. *Wood or aquatic Lychnis with a ſingle purple flower, frequently called Bachelors Button.*
4. Lychnis (*Alba*) floribus diœcis, calycibus inflatis hirſutis. *Campion with male and female flowers growing on different plants, and ſwollen hairy empalements.* Lychnis ſylveſtris, alba, ſimplex. C. B. P. 204. *Wild campion with a ſingle white flower.*
5. Lychnis (*Floſcuculi*) petalis quadrifidis, fructu ſubrotundo. Hort. Cliff. 174. *Campion with quadrifid petals, and a roundiſh fruit.* Lychnis pratenſis flore laciniato ſimplici. Mor. Hiſt. 2. p. 537. *Meadow Campion with a ſingle jagged flower, commonly called Ragged Robin.*
6. Lychnis (*Alpina*) petalis bifidis corymboſis. Lin. Sp. Plant. 436. *Campion with bifid petals, and flowers growing in a corymbus.* Silene floribus in capitulum congeſtis. Haller. Helv. 376. *Lychnis with flowers collected in a head.*
7. Lychnis (*Siberica*) petalis bifidis, caule dichotomo, foliis ſubhirtis. Lin. Sp. Plant. 437. *Campion with bifid petals, a ſtalk divided by pairs, and leaves which are ſomewhat hairy.*
8. Lychnis (*Luſitanica*) caule erecto, calycibus ſtriatis acutis, petalis diſſectis. Plat. 170. *Campion with an erect ſtalk, ſtriped acute empalements, and petals cut into many parts.*
9. Lychnis (*Apetala*) calyce inflato, corollâ calyce breviore, caule ſubunifloro. Lin. Sp. Plant. 437. *Campion with a ſwollen empalement, the petals of the flower ſhorter than the cup, and ſtalks having chiefly one flower.* Lychnis ſylveſtris alba, calyce amplo veſi-

cario. Vaill. *Wild white Campion with a large inflated empalement.*

The firſt ſort is commonly known by the title of Scarlet Lychnis; of which there is one with double flowers, which is moſt eſteemed for the ſize of the flowers and multiplicity of the petals; as alſo for the duration of the flowers, which continue much longer in beauty than the ſingle flowers, ſo that the latter is not much cultivated at preſent, though the flowers of this are very beautiful; and as the plants are ſo eaſily propagated by ſeed, they may ſoon be had in greater plenty than thoſe with double flowers, which do not produce ſeeds. Of the ſingle ſort there are three varieties, the deep ſcarlet, the fleſh-colour, and the white, but the firſt is the moſt beautiful.

This is eaſily propagated by ſeeds, which ſhould be ſown on a border expoſed to the eaſt, in the middle of March. The plants will appear in April, when if the ſeaſon is dry, they ſhould be refreſhed with water two or three times a week. By the beginning of June the plants will be fit to remove, when there ſhould be a bed of common earth prepared to receive them; into which they ſhould be planted at about four inches apart, obſerving to water and ſhade them till they have taken root; after which time they will require no other care but to keep them clean from weeds till the following autumn, when they ſhould be tranſplanted into the borders of the pleaſure-garden, where they are to continue. The ſummer following theſe plants will flower and produce ripe ſeeds, but the roots will abide ſeveral years and continue to flower. This ſort flowers in June and July, and the ſeeds ripen in autumn. It may alſo be propagated by offſets, but as the ſeeds ripen ſo freely, few perſons trouble themſelves to propagate the plants any other way. The French call this plant Jeruſalem Croſs.

The ſort with double flowers is a valuable plant, the flowers are very double, and of a beautiful ſcarlet colour. This hath a perennial root, from which ariſe two, three, or four ſtalks, according to the ſtrength of the roots; theſe in rich moiſt land, grow upwards of four feet high; the ſtalks are ſtrong, erect, and hairy. They are garniſhed the whole length with ſpear-ſhaped leaves ſitting cloſe to the ſtalks, placed oppoſite; and juſt above each pair of leaves, there are four ſmaller leaves ſtanding round the ſtalk. The flowers are produced in cloſe cluſters ſitting upon the top of the ſtalk; when the roots are ſtrong, the cluſters of flowers will be very large, ſo they make a fine appearance, the flowers being very double, and of a bright ſcarlet colour. They appear the latter end of June, and in moderate ſeaſons continue near a month in beauty. The ſtalks decay in autumn, and new ones ariſe in the ſpring. This was originally produced from the ſeeds of the ſingle ſort, and is propagated by ſlips taken from the roots in autumn; but as this is a ſlow method of increaſing the plants, the beſt way to have them in plenty, is to cut off the flower-ſtalks in June before the flowers appear, which may be cut into ſmall lengths, each of which ſhould have three or four joints, which ſhould be planted on an eaſt border of ſoft loamy earth, putting three of the joints into the ground, leaving one eye juſt level with the ſurface; theſe muſt be watered, and then covered cloſe with bell or hand-glaſſes, ſo as to exclude the outward air, and ſhaded with mats when the ſun ſhines hot upon them. The cuttings ſo managed will put out roots in five or ſix weeks, when they muſt be expoſed to the open air, and in very dry weather they ſhould be now and then refreſhed with water, but it muſt not be repeated too often, nor given in large quantities, for too much moiſture will cauſe them to rot. Theſe will make good plants by the following autumn, when they may be tranſplanted into the borders of the pleaſure-garden, where they will flower the following ſummer.

Some people who are covetous to have their plants flower, ſuffer the ſtalks to remain till the flowers are decayed, and then cut them off to plant; but by that time the ſtalks are grown hard, ſo but few of them ſucceed, and thoſe which do, will not be near ſo good plants as thoſe which are planted earlier; therefore it will be better to ſacrifice the flowers of ſome roots for this purpoſe. Theſe plants delight in a ſoft, rich, loamy ſoil, not too moiſt or ſtiff, in which they will thrive and flower very ſtrong, but they do not care for much dung, which very often cauſes the roots to canker and rot, ſo that in the rich dunged lands about London, they do not thrive well. As theſe plants grow tall, they ſhould be planted in the middle of large borders, and not crowded with other plants, for their roots extend to a large diſtance; ſo if they are incommoded by other roots, it will ſtint their growth.

I have not ſeen any double flowers of the two other varieties, but have been informed that there are of both the white and the fleſh-colour with double flowers in ſome of the French gardens. Theſe make a variety, but are not ſo beautiful as the ſcarlet, ſo are not much eſteemed.

The ſecond ſort is commonly called Red German Catchfly. This hath been found growing naturally upon the rocks in Edinburgh Park, and in ſome places in Wales. It was formerly cultivated in flower-gardens for ornament, but ſince this ſort with double flowers hath been produced, the ſingle has been almoſt baniſhed out of the gardens. This hath long, narrow, Graſs-like leaves, which come out from the root without order, ſitting cloſe to the ground; between theſe come up ſtrait ſingle ſtalks, which in good ground riſe a foot and half high; at each joint of the ſtalk come out two leaves oppoſite, of the ſame form as the lower, but decreaſe in their ſize upward; under each pair of leaves, for an inch in length, there ſweats out of the ſtalk a glutinous liquor, which is almoſt as clammy as birdlime, ſo that the flies which happen to light upon theſe places, are faſtened to the ſtalk, where they die, from whence it had the title of Catchfly. The ſtalk is terminated by a cluſter of purple flowers, and from the two upper joints come out on each ſide of the ſtalk a cluſter of the ſame flowers, ſo that the whole form a ſort of looſe ſpike. Theſe appear in the beginning of May, and the ſingle flowers are ſucceeded by roundiſh ſeed-veſſels, which are full of ſmall angular ſeeds ripening in July.

It may be propagated in plenty by parting of the roots in autumn, at which time every ſlip will grow; or if the ſeeds are ſown in the ſame manner as is directed for the firſt ſort, the plants with ſingle flowers may be raiſed in plenty. This delights in a light moiſt ſoil and a ſhady ſituation.

The double flowering of this ſort was accidentally obtained from the ſeeds of the ſingle. This hath not been known forty years in the Engliſh gardens, but it is now ſo common as to have excluded that with ſingle flowers; it differs only from that in the doubleneſs of the flowers. As this never produces ſeeds, ſo it can only be propagated by parting and ſlipping of the roots; the beſt time for this is in autumn, at which time every ſlip will grow. If this is performed in September, the ſlips will have taken good root before the froſt, and will flower well the following ſummer; but if they are expected to flower ſtrong, the roots muſt not be divided into ſmall ſlips, though for multiplying the plants, it matters not how ſmall the ſlips are. Theſe ſhould be planted on a border expoſed to the morning ſun, and ſhaded when the ſun is warm till they have taken root. If the ſlips are planted in the beginning of September, they will be rooted ſtrong enough to plant in the borders of the flower-garden by the middle or latter end of October. The roots of this ſort multiply ſo faſt, as to make it neceſſary to tranſplant and part them every year; for when they are let remain longer, they are very apt to rot. This ſort requires the ſame ſoil and ſituation as the former.

The third ſort grows naturally by the ſide of ditches and in moiſt paſtures in many parts of England, ſo is ſeldom admitted into gardens; it hath a perennial root, from which ariſe many branching diffuſed ſtalks from two to three feet high, garniſhed with oval acute-pointed leaves, placed by pairs at each joint, and are terminated by cluſters of purple flowers, which appear in April and May. The male flowers grow upon ſeparate plants from the female. The latter produces ſeeds which ripen in July; the ſtalks decay in autumn, but the roots continue ſeveral years.

There is a variety of this with double flowers, which is cultivated in gardens, by the title of Red Bachelor's Button. This is an ornamental plant, and continues long in flower. It is propagated by ſlips, which ſhould be planted the beginning of Auguſt in a ſhady border of loamy earth, where they will take root in about ſix weeks or two months, and may then be tranſplanted into the borders of the flower-garden. Theſe roots ſhould be annually tranſplanted, otherwiſe they frequently rot; and young plants muſt be propagated by ſlips to ſupply the decay of the old roots, which are not of very long duration. This ſort thrives beſt in a ſoft loamy ſoil, and in a ſhady ſituation, where they have only the morning ſun.

The fourth ſort is very common upon dry banks on the ſide of roads in moſt parts of England, ſo is not admitted into gardens; there is a variety of this with purple flowers, which I find is by ſome ſuppoſed to be the ſame as the third, but is very different, for the ſtalks of this are branched out much more; the leaves are longer and more veined, and the flowers of this ſtand ſingly upon pretty long foot-ſtalks, ſo are not produced in cluſters like thoſe of the third. This is alſo very hairy, and the empalement of the flowers is ſwollen like inflated bladders. This flowers near a month after the other, but the male and female flowers grow upon different plants, as in the former.

There is a variety of this with double flowers, which is propagated in gardens by the title of Double white Bachelor's Button, and is an ornamental plant in the flower-garden; though being white it doth not make ſo good an appearance as the other, however it adds to the variety. This is propagated in the ſame way as the double ſort before-mentioned, but the plants will thrive in a drier ſoil, and a more open expoſure than that.

The fifth ſort grows very common in moiſt meadows, and by the ſide of rivers in moſt parts of England, where it is intermixed with the Graſs. This riſes with upright unbranched ſtalks near a foot and a half high, garniſhed with narrow ſpear-ſhaped leaves, placed by pairs oppoſite at each joint. The ſtalks are ſlender, channelled, and are terminated by ſix or ſeven purple flowers upon pretty long foot-ſtalks, which branch out. The empalement of the flower is ſtriped with purple, and the petals of the flowers are deeply jagged in four narrow ſegments, which appear as if torn; from whence the country people have given it the appellation of Ragged Robin. It flowers in May, and the ſeeds ripen in July. This ſort is never kept in gardens, but there is a variety of it with very double flowers, which is propagated by the gardeners for ornament. It only differs from the ſingle in the multiplicity of the petals, and produces no ſeeds, ſo is propagated by ſlips in the ſame manner as the ſecond ſort. It is commonly known by the title of Double Ragged Robin.

The ſixth ſort grows naturally on the Alps, in Lapland, and the other cold parts of Europe. This is a perennial plant which delights in a moiſt ſoil. The ſtalks of this are erect, half a foot high, garniſhed with narrow ſpear-ſhaped leaves placed by pairs oppoſite, like the former ſort, but are a little ſhorter and broader; the bottom leaves are broader than thoſe upon the ſtalks, and ſit cloſe to the ground; they are ſmooth, and of a deep green: the flowers are produced in a corymbus on the top of the ſtalk, ſitting cloſe together; they are of a purple colour, and the petals are cut in the middle. This flowers the beginning of June, and the ſeeds ripen in Auguſt. It is propagated by ſeeds, and alſo by parting of the roots; it muſt have a moiſt ſoil and a ſhady ſituation, otherwiſe the plants will not thrive. The time for tranſplanting the plants, and parting the roots, is the ſame as for the ſecond ſort, and the ſeeds may be ſown upon a ſhady border in March. In dry weather the ground muſt be kept moiſt, otherwiſe the ſeeds will not grow. When the plants come up, and are fit to remove, they ſhould be tranſplanted into a ſhady border, where they may remain to flower.

The ſeventh ſort grows naturally in Siberia: this hath a perennial root, from which ariſe many narrow leaves ſitting cloſe to the ground. The ſtalks riſe a foot high, dividing into branches by pairs. The flowers grow out from the diviſion of the branches, as alſo at the top of the ſtalks. They are compoſed of five white petals, which are divided in the middle; theſe appear in June, and are ſucceeded by roundiſh capſules filled with ſmall angular ſeeds, which ripen in Auguſt. This requires the ſame treatment as the former ſort.

The eighth ſort was brought from Portugal to England, and is probably a variety of one with ſingle flowers, which grows naturally in that country, but is different from any we have in England. This approaches neareſt to the Double Ragged Robin, but is different from that. It hath a perennial root, from which ariſe many oblong narrow leaves ſitting cloſe to the ground. It divides into ſeparate heads like the ſecond ſort, and from each of theſe come out an upright ſtalk about nine inches high, which divides upwards by pairs, and from the middle of each diviſion comes out a ſlender foot-ſtalk two inches long, ſuſtaining one double purple flower at the top, whoſe petals are very much jagged at their points; the empalements of the flowers are marked with deep purple ſtripes. From the ſide of the ſtalks there are alſo foot-ſtalks come out at the wings, which for the moſt part ſuſtain but one flower, though ſometimes they have two; theſe flowers being very double, are never ſucceeded by ſeeds. The uſual time of this plant flowering is in June, but ſometimes it ſends out freſh ſtalks, which have flowers in the autumn. It is propagated by ſlips in the ſame manner as the third and fourth ſorts, but coming from a warm country, it is impatient of much cold, and requires a particular treatment, for it does not thrive well in pots; nor will it live through the winter in open borders, ſo that the only ſituation in which I have ſeen it thrive, was where it was planted as cloſe as poſſible to a ſouth wall in dry undunged earth; for in rich or moiſt ground the roots preſently rot, as they alſo do when they are watered. If they are planted in brick rubbiſh, they will ſtill do better. I was favoured with this plant by John Browning, Eſq; of Lincoln's-inn, who received it from Portugal.

The ninth ſort grows naturally in the northern parts of Europe. It is like the fourth ſort, but the petals of the flowers do not extend beyond the empalement, and the empalements are much larger and more ſwollen.

The other Species of Lychnis are now ranged under the following genera, viz. Agrostemma, Cucubalus, Saponaria, and Silene, to which articles the reader is deſired to turn for thoſe which are not here enumerated.

LYCIUM. Lin. Gen. Plant. 232. Jaſminoides. Niſſol. Act. R. Par. 1711. Rhamnus. C. B. P. 477. Boxthorn.

The Characters are,

The flower hath a ſmall, obtuſe, permanent empalement, which is erect, and divided into five parts at the top; the flower is funnel-ſhaped, of one petal, with an incurved tube, whoſe brim is cut into five obtuſe ſegments, which ſpread open. It has five awl-ſhaped ſtamina, which are a little inclined and ſhorter than the tube, terminated by erect ſummits. In the center is ſituated a roundiſh germen ſupporting a ſingle ſtyle, which is longer than the ſtamina, crowned by a thick bifid ſtigma; the germen afterwards becomes a roundiſh berry with two cells, incloſing kidney-ſhaped ſeeds faſtened to the middle partition.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, which includes thoſe plants whoſe flowers have five ſtamina and one ſtyle.

The Species are,

1. Lycium (*Afrum*) foliis lineari-longioribus, tubo florum longiori, ſegmentis obtuſis. *Boxthorn with longer linear leaves, a longer tube to the flower, and obtuſe ſegments.* Lycium foliis linearibus. Hort. Cliff. 57. *Boxthorn with linear leaves.*
2. Lycium (*Italicum*) foliis lineari-brevioribus, tubo florum breviori, ſegmentis ovalibus patentiſſimis. *Boxthorn with ſhorter linear leaves, a ſhorter tube to the flower, and oval ſegments ſpreading open.*
3. Lycium (*Salicifolium*) foliis cuneiformibus. Vir. Cliff. 14. *Boxthorn with wedge-ſhaped leaves.* Jaſminoides aculeatum, ſalicis folio, flore parvo ex albo purpuraſcente. Mitchel. Gen. 224. *Prickly Baſtard Jaſmine with a Willow leaf, and a ſmall purpliſh white flower.*
4. Lycium (*Barbarum*) foliis lanceolatis craſſiuſculis, calycibus trifidis. Lin. Sp. Plant. 192. *Boxthorn with ſpear-ſhaped thick leaves, and trifid empalements.* Jaſminoides aculeatum, polygoni folio, floribus parvis albidis. Shaw. Afr. 349. f. 349. *Prickly Baſtard Jaſmine, with a Knot-graſs leaf, and ſmall whitiſh flowers.*
5. Lycium (*Chinenſe*) foliis ovato-lanceolatis, ramis diffuſis, floribus ſolitariis patentibus alaribus, ſtylo longiori. *Boxthorn with oval ſpear-ſhaped leaves, diffuſed branches, and ſingle ſpreading flowers proceeding from the ſides of the branches, with a longer ſtyle.*
6. Lycium (*Halimifolium*) foliis lanceolatis acutis. *Boxthorn with ſpear-ſhaped acute leaves.* Jaſminoides Sinenſe halimi folio longiore & anguſtiore. Du Ham. 306. *China Baſtard Jaſmine with a narrower and longer leaf.*
7. Lycium (*Capenſe*) foliis oblongo-ovatis, craſſiuſculis, confertis, ſpinis robuſtioribus. *Boxthorn with oblong, oval, thick leaves growing in cluſters, and ſtronger ſpines.*
8. Lycium (*Anguſtifolium*) foliis lineari-lanceolatis confertis, calycibus brevibus acutis. *Boxthorn with linear ſpear-ſhaped leaves growing in cluſters, and ſhort acute empalements.*
9. Lycium (*Inerme*) inermis, foliis lanceolatis, alternis, perennantibus. *Smooth Boxthorn, with ſpear-ſhaped ever-green leaves placed alternate.*
10. Lycium (*Cordatum*) foliis cordato-ovatis, ſeſſilibus, oppoſitis perennantibus, ſpinis craſſis bigeminis, floribus confertis. *Lycium with oval heart-ſhaped leaves placed oppoſite, which are ever-green, and ſit cloſe to the ſtalks, with thick double ſpines, and flowers growing in cluſters.* Arbor Africana ſpinoſa, foliis craſſis cordatis & conjugatis, ſpinis craſſis bigeminis. Herm. Cat. 4. *Prickly African-tree with thick heart-ſhaped leaves growing by pairs, and thick double ſpines.*

The firſt ſort grows naturally in Spain, Portugal, and at the Cape of Good Hope. This riſes with irregular ſhrubby ſtalks ten or twelve feet high, ſending out ſeveral crooked knotty branches, covered with a whitiſh bark, and armed with long ſharp ſpines, upon which grow many cluſters of narrow leaves; theſe thorns often put out one or two ſmaller on their ſides, which have ſome cluſters of ſmaller leaves upon them; the branches are garniſhed with very narrow leaves an inch and a half long, and at the baſe of theſe come out cluſters of ſhorter and narrower leaves. The flowers come out from the ſide of the branches, ſtanding upon ſhort foot-ſtalks; they have a ſhort permanent empalement of one leaf, which is tubulous, and cut into five ſegments at the brim; it is funnel-ſhaped, of one petal, with a long incurved tube, cut into five obtuſe ſegments at the brim; they are of a dull purple colour, and have five ſtamina almoſt as long as the tube, with erect ſummits. In the center is ſituated a roundiſh germen, ſupporting a ſtyle which is longer than the ſtamina, crowned by a bifid ſtigma. The germen afterward turns to a roundiſh fleſhy berry, of a yellowiſh colour when ripe, incloſing ſeveral hard ſeeds. This uſually flowers in June and July, and the ſeeds ripen in the autumn; but there is frequently a few flowers come out in all the ſummer months.

It may be propagated either by ſeeds, cuttings, or layers. If by ſeeds, they ſhould be ſown in the autumn ſoon after they are ripe; for if they are kept out of the ground till ſpring, they ſeldom come up the firſt year. If the ſeeds are ſown in pots, the pots ſhould be plunged into ſome old tan in the winter, and in very ſevere froſt covered with Peas-haulm or ſtraw, but in mild weather ſhould be open to receive the wet; in the ſpring the pots ſhould be plunged into a moderate hot-bed, which will ſoon bring up the plants; theſe muſt be inured to bear the open air as ſoon as the danger of froſt is over, and when they are three inches high, they may be ſhaken out of the pots, and each planted in a ſmall ſeparate pot, filled with loamy earth, and placed in the ſhade till they have taken new root, when they may be removed to a ſheltered ſituation, where they may remain till the autumn; then they ſhould be either removed into the green-houſe, or placed under a hot-bed frame to ſhelter them from hard froſt; for theſe plants are too tender to live in the open air in England, ſo they muſt be kept in pots and treated in the ſame way as Myrtles, and other hardy green-houſe plants; but when the plants are grown ſtrong, there may be a few of them planted in the full ground in a warm ſituation, where they will live in moderate winters, but in hard froſts they are commonly deſtroyed. If the cuttings of theſe plants are planted in a ſhady border in July, and duly watered, they will take root, and may then be treated in the ſame way as the ſeedling plants.

The ſecond ſort was raiſed in the Chelſea garden from ſeeds which came from the Cape of Good Hope. This hath an irregular ſhrubby ſtalk like the former, but ſeldom riſe more than four or five feet high; the large leaves are ſhorter and a little broader than thoſe of the firſt, but the tufts of ſmall leaves are narrower; the tube of the flower is ſhorter, the brim is deeper cut into oval ſegments which ſpread open; the empalement is ſhorter, and cut into acute ſegments; the flowers and fruit are alſo ſmaller. Theſe differences are permanent, in all the plants which I have two or three times raiſed from ſeeds. It flowers about the ſame time as the firſt, and may be propagated in the ſame way; the plants alſo require the ſame culture.

The third ſort grows naturally in the hedges in the ſouth of France, in Spain and Italy. This hath many irregular ſhrubby ſtalks, which riſe eight or nine feet high, ſending out ſeveral irregular branches, covered with a white bark, and armed with pretty ſtrong thorns; the leaves are narrow at bottom, growing broader upward, and are of a pale green colour. The flowers come out from the ſide of the branches; they are of a purpliſh white colour and ſmall, ſo make no great appearance. This ſort flowers in June and July, but rarely produces any ſeeds in this country. The leaves of this remain till winter, when they fall off.

It may be propagated by cuttings or layers, in the ſame manner as the firſt ſort. The plants will live abroad in a ſheltered warm ſituation, but in very hard froſt they ſhould be covered with ſtraw or litter, otherwiſe the branches will be killed, and ſometimes the roots are deſtroyed where they have not ſome cover.

The fourth ſort was brought from Africa by the late Dr. Shaw, where it grows naturally. This hath a ſhrubby ſtalk which riſes ſeven or eight feet high, ſending out ſeveral irregular branches, which are armed with ſtrong ſpines, and garniſhed with ſhort, thick, ſpear-ſhaped, oval leaves, which ſtand without order. The flowers come out from the ſide of the branches; they are ſmall and white, ſo make little appearance. This flowers in July and Auguſt, but does not produce ſeeds in England. It may be propagated by cuttings in the ſame way as the firſt ſort, but is too tender to live in the open air in winter in this country, ſo the plants muſt be kept in pots, and removed into the green-houſe in autumn, and treated in the ſame way as other hardy kinds of green-houſe plants.

The fifth ſort grows naturally in China, from whence the ſeeds were brought to England a few years paſt, and the plants were raiſed in ſeveral gardens, and by ſome were thought to be the Thea. This riſes with weak, irregular, diffuſed branches to a great height, but require ſupport, otherwiſe they will trail upon the ground: I have meaſured ſome of theſe branches, which in one year has been upward of twelve feet long: the lower leaves are more than four inches long, and three broad in the middle: they are of a light green and a thin conſiſtence, placed without order on every ſide the branches; as the ſhoots advance in length, ſo the ſize of the leaves diminiſh, and toward the upper part they are not more than an inch long, and a quarter of an inch broad; they ſit cloſe to the ſtalks on every ſide. The flowers come out ſingly at every joint toward the upper part of the branches, ſtanding upon ſhort ſlender foot-ſtalks; they are of a pale colour, with ſhort tubes; the brims are ſpread open broader than either of the former ſorts, and the ſtyle is conſiderably longer than the tube of the flower. This ſort flowers in Auguſt, September, and October; the plant is very hardy, and retains its leaves till November before they decay. It propagates faſt enough by its creeping roots, which ſend out ſuckers at a great diſtance, and the cuttings thruſt into the ground will take root as freely as Willows.

The ſixth ſort grows naturally in China, from whence the ſeeds were brought to the Royal Garden at Paris, and the ſeeds were ſent me by Dr. Bernard de Juſſieu, demonſtrator of the plants in that garden. This riſes with a ſhrubby ſtalk to the height of four or five feet, ſending out many irregular branches, covered with a very white bark, and armed with a few ſhort ſpines; the leaves are about three inches long, and one broad in the middle; they are placed alternately on the branches, and are of a pale green colour. The flowers of this ſort appear in June and July, which are ſucceeded by ſmall round berries that ripen in the autumn, when they are as red as coral. This ſort is propagated by cuttings, which ſhould be planted in the ſpring before they begin to ſhoot, in a border expoſed to the morning ſun, where they will take root very freely; but theſe ſhould not be removed till the autumn, when they may be planted to cover walls, for the branches are too weak to ſupport themſelves; and as the leaves continue green as long as any of the deciduous plants, ſo they are proper plants for ſuch purpoſes.

The ſeventh ſort was raiſed in the Chelſea garden from ſeeds, which were brought me from the Cape of Good Hope. This riſes with ſhrubby branching ſtalks ſeven or eight feet high, which are armed with long ſtrong thorns, that have ſeveral cluſters of leaves upon them; the branches are garniſhed with ſmall, oblong, oval leaves, which are placed without order; ſometimes they come out in ſmall cluſters from one point, at others they are ſingle, ſtanding on every ſide the ſtalk; theſe are of a light green, and a pretty thick conſiſtence, continuing green all the year. Theſe plants have not as yet flowered here, ſo I can give no account of them; but by the fruit which I received entire, I make no doubt of its belonging to this genus.

This ſort is pretty hardy, for it has lived abroad four winters, where it was planted againſt a ſouth-eaſt wall. It may be propagated either by layers or cuttings, in the ſame manner as the firſt; and when the plants have obtained ſtrength, they may be planted in a warm ſituation, where they will live with very little ſhelter in ſevere froſt. The branches of this ſort are ſtronger than thoſe of the former, ſo will not require the ſame ſupport. It will be proper to keep a plant of this in ſhelter to preſerve the kind, leſt thoſe in the open air ſhould be deſtroyed.

The eighth ſort has much the appearance of the firſt, but the branches are not ſo ſtrongly armed with thorns; they have alſo a whiter bark, the leaves are broader and of a lighter green, ſtanding in cluſters at every joint. The flowers are ſmaller, of a deeper purple colour, and have much ſhorter empalements, which are cut into acute ſegments. It flowers at the ſame time with the firſt ſort, but does not produce any ſeeds in this country; it is not ſo hardy as the former ſort, ſo requires protection from very hard froſt; therefore the plants ſhould be kept in pots and houſed in the winter, treating them in the ſame way as other hardy green-houſe plants. It may be propagated by cuttings or layers, in the ſame way as the firſt ſort.

The ninth ſort has been long an inhabitant of the Chelſea garden; it was raiſed from ſeeds which came from China, and was for many years taken for the Tea-tree, till it produced ſome flowers, which diſcovered its true genus. This riſes with a ſtrong woody ſtalk ſix or ſeven feet high, ſending out many ſmooth branches, which are covered with a brown bark having no thorns; they are garniſhed with ſpear-ſhaped leaves about three inches long, and near three quarters of inch broad, placed alternately on the branches, ſtanding upon ſhort foot-ſtalks; they are of a deep green, and continue all the year. The flowers are white, and of the ſame ſhape with the others of this genus, but there has not been any ſeeds of this ſort as yet produced in England.

This plant will live in the open air, if it is planted in a warm ſituation and a dry ſoil; but it is of ſlow growth, ſeldom ſhooting more than three or four inches in a ſeaſon; it is alſo difficult to propagate, for the branches which are laid down will not take root in leſs than two years, and the cuttings are with difficulty made to grow. The beſt time to plant them is in May, in pots filled with light loamy earth, plunging them into an old bed of tanners bark, covering the pots cloſe with bell or hand-glaſſes, to exclude the external air; theſe ſhould be ſhaded every day from the ſun; theſe cuttings ſhould be refreſhed with water once a week, but it muſt not be given to them in too great plenty. Thoſe cuttings which ſucceed, will have put out roots by the beginning of Auguſt, when they may be taken up and planted in ſmall pots, placing them in the ſhade till they have taken new root; and then they may be placed with other hardy exotic plants in a ſheltered ſituation, till the end of October, when they may be put under a common frame to ſhelter them in winter. When the plants have acquired ſtrength, they may be ſhaken out of the pots, and planted in the full ground in a warm ſituation, where, if they are ſheltered in ſevere froſts, they will thrive better than in pots.

The tenth ſort grows naturally at the Cape of Good Hope, from whence the ſeeds were ſent to Holland a few years paſt, where the plants were raiſed. This is a low ſhrubby plant, which ſends out branches from the ground upward, which are covered with a dark green bark, and are armed with ſhort ſtrong thorns, which come out by pairs, and ſometimes there are double pairs upon the ſame foot-ſtalk; theſe are ſituated juſt below the leaves, and where there are four, two of them point upward, and the other two downward. The leaves are heart-ſhaped, not much larger than thoſe of the Box-tree, of the ſame conſiſtence and colour, terminating in acute points; they are placed by pairs oppoſite, upon very ſhort foot-ſtalks, ſtanding pretty cloſe together; theſe continue green all the year. The flowers come out from the ſide of the branches upon ſhort ſlender foot-ſtalks, each ſupporting five or ſix ſmall white flowers, which grow in a cluſter at the top; theſe have very ſhort empalements, and pretty long tubes, divided at the brim into five acute ſegments. Theſe flowers have an agreeable odour; they appear in July and Auguſt, but are ſeldom ſucceeded by ſeeds in England.

This ſort may be propagated by cuttings in the ſame manner as the firſt ſort, which, if planted in July, and ſhaded from the ſun, will take root very freely; then they ſhould be planted into ſeparate ſmall pots, and placed in the ſhade till they have taken new root, after which they may be treated in the ſame manner as the former ſort. This plant has not as yet been planted in the full ground in England, but it lives through the winter under a common frame.

The other ſpecies which were included in this genus, are now removed to Celastrus.

LYCOPERSICON. Tourn. Inſt. R. H. 150. tab. 63. Solanum. Lin. Gen. Plant. 224. [of Λύκος, a wolf, and Perſica, *Lat.* a Peach.] Love Apples, or Wolf's Peach.

The Characters are,

The flower has a permanent empalement of one leaf, which is cut into five acute ſegments at the top, and is permanent. The flower has one petal, which is wheel-ſhaped, with a very ſhort tube, and a large five-cornered brim, which ſpreads open and is plaited. It hath five ſmall awl-ſhaped ſtamina, terminated by oblong ſummits which cloſe together. It hath a roundiſh germen, ſupporting a ſlender ſtyle the length of the ſtamina, crowned by an obtuſe ſtigma. The germen afterward becomes a roundiſh fleſhy fruit or berry, divided into ſeveral cells, incloſing many flat ſeeds.

This genus of plants is ranged in the ſeventh ſection of Tournefort's ſecond claſs, which includes the herbs with a wheel-ſhaped flower of one leaf, whoſe pointal becomes a ſoft fruit. Dr. Linnæus has joined this genus, and alſo the Melongena of Tournefort, to the Solanum, which he places in the firſt ſection of his fifth claſs, which includes thoſe plants whoſe flowers have five ſtamina and one ſtyle; but as there are numerous ſpecies of Solani, ſo it is much better to keep theſe ſeparate, to avoid confuſion, which if we allow the fruit as a characteriſtic note, ſhould be done; for as the fruit of the Solanum has but two cells, and the fruit of this many, ſo that diſtinction may be allowed to ſeparate the genera.

The Species are,

1. Lycopersicon (*Galeni*) caule inermi herbaceo, foliis pinnatis inciſis, fructu rotundo glabro. *Love Apple with an herbaceous unarmed ſtalk, pinnated cut leaves, and a ſmooth round fruit.* Lycoperſicon Galeni. Ang. 217. *The Wolf Peach of Galen.*
2. Lycopersicon (*Eſculentum*) caule herbaceo hirſutiſſimo, foliis pinnatis, inciſis, fructu compreſſo ſulcato. *Love Apple with a very hairy herbaceous ſtalk, winged cut leaves, and a compreſſed furrowed fruit.* Solanum pomiferum, fructu rotundo ſtriato molli. C. B. P. 167. *Apple-bearing Nightſhade, with a ſoft, round, ſtriated fruit, commonly called Tomatas by the Spaniards.*
3. Lycopersicon (*Æthiopicum*) caule inermi herbaceo, erecto, foliis ovatis dentato angulatis, ſubſpinoſis fructu ſubrotundo ſulcato. *Love Apple with an herbaceous, erect, unarmed ſtalk, oval angular leaves indented, having a few ſpines, with a roundiſh furrowed fruit.* Lycoperſicon fructu ſtriato duro. Tourn. Inſt. R. H. 150. *Wolf's Peach with a hard ſtriated fruit.*
4. Lycopersicon (*Pimpinellifolium*) caule inermi herbaceo, foliis inæqualiter pinnatis, foliolis obtuſe-dentatis, racemis ſimplicibus. *Love Apple with an herbaceous unarmed ſtalk, leaves unequally winged, whoſe lobes are bluntly indented, and ſimple branches of flowers.* Licoperſicon inodorum. Juſſ. *Wolf's Peach having no ſcent.*
5. Lycopersicon (*Peruvianum*) caule inermi herbaceo, foliis pinnatis tomentoſis inciſis, racemis bipartitis folioſis. *Love Apple with an unarmed herbaceous ſtalk, winged cut leaves, which are downy, and a leafy double ſpike of flowers.* Lycoperſicon pimpinellæ ſanguiſorbæ foliis. Feuill. Obſ. 3. p. 37. *Wolf's Peach with leaves like Burnet.*
6. Lycopersicon (*Procumbens*) caule herbaceo, procumbente, foliis pinnatifidis, glabris, floribus ſolitariis alaribus. *Love Apple with an herbaceous trailing ſtalk, wing-pointed ſmooth leaves, and flowers growing ſingly from the wings of the ſtalk.*
7. Lycopersicon (*Tuberoſum*) caule inermo herbaceo, foliis pinnatis integerrimis. *Love Apple with an unarmed herbaceous ſtalk, and winged leaves which are entire.* Solanum tuberoſum eſculentum. C. B. P. 167. *Eſculent tuberous Nightſhade, commonly called Potatoe, by the Indians Batatas.*

The firſt ſort here mentioned is ſuppoſed to be the Lycoperſicon of Galen. This is an annual plant, with an herbaceous, branching, hairy ſtalk, which will riſe to the height of ſix or eight feet, if ſupported, otherwiſe the branches will fall to the ground; theſe are garniſhed with winged leaves of a very rank diſagreeable odour, compoſed of four or five pair of lobes terminated by an odd one; theſe are cut on their edges, and end in acute points. The flowers come out from the ſide of the branches upon pretty long foot-ſtalks, each ſuſtaining ſeveral yellow flowers, ranged in a ſingle long bunch or thyrſe, and are ſucceeded by round, ſmooth, pulpy fruit, about the ſize of a large Cherry. There are two varieties of this, one with yellow, and the other with red fruit. The plants flower from June till the froſt ſtops them, and the fruit ripens in ſucceſſion from the end of July, till the froſt kills the plants; this ſort is uſed in medicine.

The ſecond ſort is very like the firſt, excepting the fruit, which differ greatly; for thoſe of the ſecond ſort are very large, compreſſed at both ends, and deeply furrowed all over the ſides. This ſort never varies to the other, ſo that it is undoubtedly a diſtinct ſpecies. This is the ſort which is commonly cultivated to put into ſoups; and the Portugueze, Spaniards, and ſome others, uſe them in many of their ſauces, to which they give an agreeable acid flavour.

The third ſort is alſo annual; this riſes with an erect herbaceous ſtalk a foot and a half high, dividing into ſeveral branches, garniſhed with oval angular leaves, from three to four inches long, and almoſt three inches broad in the middle; they are placed alternately upon pretty long foot-ſtalks, which have one or two ſhort ſpines upon them, as there alſo is upon the midrib of the leaves. The flowers come out ſingly upon foot-ſtalks from the ſide of the branches; they are white, and are ſucceeded by red ſtriated fruit, which are firmer than thoſe of the other ſorts, and about the ſize of Cherries. This fruit ripens in the autumn, and the plants decay ſoon after.

The fourth ſort is ſomewhat like the firſt, but the leaves are unequally winged, having ſome ſmaller lobes placed between the large ones; the lobes of this are ſhorter, broader, and not cut like thoſe of the firſt, but have ſome obtuſe indentures toward their baſe. The leaves of this ſort have not that rank diſagreeable odour which the two firſt have; the fruit of it is not ſo large as thoſe of the firſt, but they are round and ſmooth, and are very late before they ripen here; ſo that unleſs the plants are raiſed early in the ſpring, they will not produce ripe fruit.

The fifth ſort is alſo annual; this hath a very branching herbaceous ſtalk, ſpreading out into many diviſions, and is not ſo hairy as the two firſt; the leaves are compoſed of a greater number of lobes, which are much ſhorter and more indented on their edges, where they are a little waved, and are downy. The flowers ſtand upon very long foot-ſtalks, which branch out and ſupport a large number of flowers at the top; theſe have a longer ſtyle than thoſe of the other ſpecies, which is permanent, remaining on the top of the fruit. This ſort is late in ripening the fruit, ſo that unleſs the plants are raiſed early in the ſpring, the fruit will not ripen in England.

The ſeeds of theſe two ſorts were ſent from Peru by Mr. Joſeph de Juſſieu to the Royal Garden at Paris, part of which was ſent me by his brother Dr. Bernard de Juſſieu, of the Royal Academy of Sciences.

The ſixth ſort was raiſed by Mr. James Gordon, gardener at Mile-end, who gave me ſome of the ſeeds, but from what country it came I could not learn. This hath very weak, trailing, ſmooth ſtalks, not more than a foot long, garniſhed with ſmooth leaves, ſtanding by pairs oppoſite; theſe are regularly cut on the ſides almoſt to the midrib, in form of a winged leaf; and theſe ſegments are alſo indented on their edges, and at their points. The flowers come out on the ſide of the ſtalks ſingly; they are of a whitiſh yellow colour, and have a pretty large ſpreading empalement, which is deeply cut at the brim into many acute ſegments which ſpread open. The flowers are ſucceeded by ſmall roundiſh berries a little compreſſed at the top, of an herbaceous yellow colour when ripe.

Theſe plants are all propagated by ſowing their ſeeds on a moderate hot-bed in March, and when the plants are come up two inches high, they ſhould be tranſplanted into another moderate hot-bed, at about four inches diſtance from each other, obſerving to ſhade them until they have taken root; after which they muſt have frequent waterings, and a large ſhare of freſh air; for if they are too much drawn while young, they ſeldom do well afterwards.

In May theſe plants ſhould be tranſplanted either into pots filled with rich light earth, or into borders near walls, pales, or Reed-hedges, to which their branches may be faſtened to ſupport them from trailing on the ground, which they otherwiſe will do, and then the fruit will not ripen; ſo that where theſe plants are cultivated for the ſake of their fruit, they ſhould be planted to a warm aſpect, and the branches regularly faſtened as they extend, that the fruit may have the advantage of the ſun's warmth to forward them, otherwiſe it will be late in the ſeaſon before they are ripe, and they are unfit for uſe before; but when the plants are brought forward in the ſpring, and thus regularly trained to the ſouth ſun, the fruit will ripen by the latter end of July, and there will be a ſucceſſion of it till the froſt kills the plants.

Some perſons cultivate theſe plants for ornament, but their leaves emit ſo ſtrong offenſive an odour on being touched, which renders them very improper for the pleaſure-garden, and their branches extend ſo wide and irregular, as to render them very unſightly in ſuch places; for as their branches cannot be kept within bounds, eſpecially when they are planted in good ground, ſo they will appear very unſightly in ſuch places; therefore the borders in the kitchen-garden, where theſe plants are placed for their fruit, muſt not be too rich, for in a moderate ſoil they will not be ſo luxuriant and more fruitful.

The Italians and Spaniards eat theſe Apples, as we do Cucumbers, with pepper, oil, and ſalt; and ſome eat them ſtewed in ſauces, &c. and in ſoups they are now much uſed in England, eſpecially the ſecond ſort, which is preferred to all the other. This fruit gives an agreeable acid to the ſoup, though there are ſome perſons who think them not wholeſome, from their great moiſture and coldneſs, and that the nouriſhment they afford muſt be bad.

The third ſort is never uſed either in the kitchen or for medicine, but the plants are preſerved for the ſake of variety, eſpecially by thoſe perſons who are lovers of botany. This ſort is propagated by ſeeds, which ſhould be ſown upon a hot-bed in the ſpring, and the plants afterward treated in the ſame manner as hath been directed for the Capſicum, with which this plant will thrive and produce plenty of fruit annually.

The ſeventh ſort is the common Potatoe, which is a plant ſo well known now, as to need no deſcription. Of this there are two varieties, one with a red and the other with a white root; that whoſe roots are red, have purpliſh flowers, but the white root has white flowers; theſe are ſuppoſed to be only accidental variations, and not diſtinct ſpecies.

The common name of Potatoe, ſeem to be only a corruption of the Indian name Batatas. This plant has been much propagated in England within thirty or forty years paſt, for although it was introduced from America about the year 1623, yet it was but little cultivated in England till of late; theſe roots being deſpiſed by the rich, and deemed only proper food for the meaner ſort of perſons; however, they are now generally eſteemed by moſt people, and the quantity of them which are cultivated near London, I believe, exceeds that of any other part of Europe.

This plant was always ranged in the genus of Solanum, or Nightſhade, and is now brought under that title again by Dr. Linnæus; but as Lycoperſicon has been eſtabliſhed as a diſtinct genus, on account of the fruit being divided into ſeveral cells, by intermediate partitions; and as the fruit of this plant exactly agrees with the characters of the other ſpecies of this genus, I have inſerted it here.

This is generally propagated by its roots, which multiply greatly if planted in a proper ſoil. The common way is, either to plant the ſmall roots or offſets entire, or to cut the larger roots into pieces, preſerving a bud or eye to each; but neither of theſe methods is what I would recommend, for when the ſmaller offſets are planted, they generally produce a greater number of roots, but theſe are always ſmall; and the cuttings of the larger roots are apt to rot, eſpecially if wet weather happens ſoon after they are planted; therefore what I would recommend is, to make choice of the faireſt roots for this purpoſe, and to allow them a larger ſpace of ground, both between the rows, as alſo in the rows, plant from plant; by which method I have obſerved, the roots have been in general large the following autumn.

The ſoil in which this plant thrives beſt, is a light ſandy loam, not too dry or over moiſt; this ground ſhould be well ploughed two or three times, in order to break and divide the parts; and the deeper it is ploughed, the better the roots will thrive. In the ſpring, juſt before the laſt ploughing, there ſhould be a good quantity of rotten dung ſpread on the ground, which ſhould be ploughed into the ground the beginning of March, if the ſeaſon proves mild, otherwiſe it had better be deferred till the middle or latter end of that month; for if it ſhould prove hard froſt after the roots are planted, they may be greatly injured, if not deſtroyed thereby: but the ſooner they are planted in the ſpring, after the danger of froſt is over, the better it will be, eſpecially in dry land. In the laſt ploughing, the ground ſhould be laid even, and then the furrows ſhould be drawn at three feet diſtance from each other, about ſeven or eight inches deep. In the bottom of this furrow the roots ſhould be laid at about one foot and a half aſunder; then the furrow ſhould be filled with the earth which came out, and the ſame continued through the whole field or parcel of land, intended to be planted.

After all is finiſhed, the land may remain in the ſame ſtate till near the time when the ſhoots are expected to appear above ground, when the ground ſhould be well harrowed over both ways, which will break the clods, and make the ſurface very ſmooth; and by doing of it ſo late, it will deſtroy the young weeds, which, by this time, will begin to make their appearance; and this will ſave the expence of the firſt hoeing, and will alſo ſtir the upper ſurface of the ground, which, if much wet has fallen after the planting, is often bound into a hard cruſt, and will retard the appearance of the ſhoots.

As I have allotted the rows of Potatoes at three feet diſtance, it was in order to introduce the hoe-plough between them, which will greatly improve theſe roots; for by twice ſtirring and breaking the ground between theſe plants, it will not only deſtroy the weeds, but alſo looſen the ground, whereby every ſhower of rain will penetrate to the roots, and greatly improve their growth; but theſe operations ſhould be performed early in the ſeaſon, before the ſtems or branches of the plants begin to fall and trail upon the ground, becauſe after that, it will be impoſſible to do it without injuring the ſhoots.

If theſe ploughings are carefully performed between the rows, and the ground between the plants in the rows hand-hoed, it will prevent the growth of weeds, till the haulm of the plants cover the ground; ſo that afterward there will be little danger of weeds growing ſo as to injure the crop; but as the plough can only go between the rows, it will be neceſſary to make uſe of a hoe to ſtir the ground, and deſtroy the weeds in the rows; and if this is carefully performed in dry weather, after the two ploughings, it will be ſufficient to keep the ground clean until the Potatoes are fit to take up.

In places where dung is ſcarce, many perſons ſcatter it only in the furrows, where the roots are planted; but this is a very poor method, becauſe when the Potatoes begin to puſh out their roots, they are ſoon extended beyond the width of theſe furrows, and the new roots are commonly formed at a diſtance from the old, ſo will be out of the reach of this dung, and conſequently will receive little benefit from it. And as moſt of the farmers covet to have a crop of Wheat after the Potatoes are taken off the ground, ſo the land will not be ſo thoroughly dreſſed in every part, nor ſo proper for this crop, as when the dung is equally ſpread, and ploughed in all over the land, nor will the crop of Potatoes be ſo good. I have always obſerved, where this method of planting the Potatoes has been practiſed, the land has produced a fine crop of Wheat afterward, and there has ſcarce one ſhoot of the Potatoe appeared among the Wheat the following ſeaſon, which I attribute to the farmers planting only the largeſt roots; for when they have forked them out of the ground the following autumn, there have been ſix, eight, or ten large roots produced from each, and often many more, and ſcarce any very ſmall roots among them; whereas, in ſuch places where the ſmall roots have been planted, there has been a vaſt number of very ſmall roots produced; many of which were ſo ſmall as not to be diſcovered when the roots were taken up, ſo have grown the following ſeaſon, and have greatly injured whatever crop was on the ground.

The haulm of theſe Potatoes is generally killed by the firſt froſt in the autumn, when the roots ſhould be taken up ſoon after, and may be laid up in ſand in any ſheltered place, where they may be kept dry, and ſecure from froſt. Indeed the people who cultivate theſe roots near London, do not wait for the decaying of the haulm, but begin to take up part of them as ſoon as their roots are grown to a proper ſize for the market, and ſo keep taking up from time to time, as they have vent for them. There are others likewiſe, who do not take them up ſo ſoon as the haulm decays, but let them remain much longer in the ground; in which there is no hurt done, provided they are taken up before hard froſt ſets in, which would deſtroy them, unleſs where the ground is wanted for other crops; in which caſe, the ſooner they are taken up the better, after the haulm is decayed. When theſe roots are laid up, they ſhould have a good quantity of ſand or dry earth laid between them, to prevent their heating; nor ſhould they be laid in too large heaps, for the ſame reaſon.

The kitchen-gardeners and farmers who live in the neighbourhood of Mancheſter, cultivate great quantities of this root, as the inhabitants of that populous town conſume abundance of them, and are much fonder of them than of any other eſculent plants; which has occaſioned an emulation among the cultivators, of endeavouring to outvie each other, in getting the roots of a proper ſize for the table early in the ſeaſon: in order to obtain this, they have made choice of thoſe roots which produced the firſt flowers, and have left them to ripen their ſeeds, which they have ſowed with great care; and the plants ſo raiſed, have generally been forwarder than the other; and by frequently repeating of this, they have ſo much improved the forwarding of the roots, as to have them fit for uſe in two months after planting; ſo that great improvements may be made by this practice, of many eſculent plants, by perſons who are curious and careful in trying the experiments.

LYCOPUS [Λυκόπους, of Λύκος, a wolf, and Ποῦς, a foot; q. d. Wolf's-foot; becauſe the ancients fancied, that the leaves of this plant reſembled the foot of a wolf,] it is commonly called Water Horehound.

This plant grows in great plenty on moiſt ſoils by the ſides of ditches and ponds in moſt parts of England, but is never cultivated in gardens, ſo that it would be needleſs to ſay any thing more of it in this place.

LYSIMACHIA. Tourn. Inſt. R. H. 141. tab. 59. Lin. Gen. Plant. 188. [this plant was ſo called of Lyſimachus, the ſon of a king of Sicily, who is ſaid to have firſt found the virtues of it.] Looſtrife; in French, *Corneille*.

The CHARACTERS are,

The empalement of the flower is permanent, and is cut into five acute ſegments, which are erect. The flower is of one petal, cut into five oblong oval ſegments to the bottom, which ſpread open. It hath five awl-ſhaped ſtamina about half the length of the petal, terminated by acute-pointed ſummits. In the center is ſituated a roundiſh germen, ſupporting a ſlender ſtyle the length of the ſtamina, crowned by an obtuſe ſtigma. The germen afterward turns to a globular capſule with one cell, opening with ten valves, and filled with ſmall angular ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, which includes the plants whoſe flowers have five ſtamina and one ſtyle.

The SPECIES are,

1. LYSIMACHIA (*Vulgaris*) paniculata, racemis terminalibus. Lin. Sp. Plant. 209. *Paniculated Looſtrife, with bunches of flowers terminating the ſtalks.* Lyſimachia lutea, major, quæ Dioſcoridis. C. B. P. 245. *Greater yellow Looſtrife of Dioſcorides.*

2. LYSIMACHIA (*Thyrſiflora*) racemis lateralibus pedunculatis. Lin. Sp. Plant. 147. *Looſtrife with lateral ſpikes of flowers growing upon foot-ſtalks.* Lyſimachia bifolia flore globoſo, luteo. C. B. P. 242. *Two-leaved Looſtrife with a yellow globular flower.*

3. LYSIMACHIA (*Atropurpurea*) ſpicis terminalibus petalis, lanceolatis, ſtaminibus corollâ longioribus. Lin. Sp. Plant. 147. *Looſtrife with ſpear-ſhaped ſpreading ſpikes of flowers terminating the branches, and ſtamina longer than the petals.* Lyſimachia Orientalis anguſtifolia flore purpureo. Tourn. Cor. 7. *Narrow-leaved Eaſtern Looſtrife with a purple flower.*

4. LYSIMACHIA (*Ephemerum*) racemis ſimplicibus terminalibus, petalis obtuſis, ſtaminibus corollâ brevioribus. Lin. Sp. Plant. 146. *Looſtrife with ſpikes of flowers terminating the ſtalks, obtuſe petals to the flower, and ſtamina ſhorter than the petal.* Lyſimachia Orientalis minor, foliis glaucis, annuentibus, flore purpureo. Hort. Piſſ. *Smaller Eaſtern Looſtrife, with nodding grayiſh leaves and a purple ſpike of flowers.*

5. LYSIMACHIA (*Ciliata*) petiolis ciliatis, floribus cernuis. Lin. Sp. Plant. 147. *Looſtrife with hairy foot-ſtalks and nodding flowers.* Lyſimachia Canadenſis Jalappæ foliis. Sarr. Canad. *Canada Looſtrife with a Jalap leaf.*

6. LYSIMACHIA (*Salicifolia*) ſpicâ ſimplici erecto terminali, petalis ovatis, ſtaminibus corollâ longioribus. *Looſtrife with a ſingle erect ſpike terminating the ſtalk, oval petals, and ſtamina longer than the flower.* Lyſimachia ſpicata, flore albo, ſalicis folio. Tourn. Inſt. R. H. 141. *Looſtrife with a ſpike of white flowers and a Willow leaf.*

7. LYSIMACHIA (*Nummularia*) foliis ſubcordatis, floribus ſolitariis, caule repente. Vir. Cliff. 13. *Looſtriſe with leaves nearly heart-ſhaped, flowers growing ſingly, and a creeping ſtalk.* Nummularia lutea major. C. B. P. 309. *Greater yellow Moneywort.*

8. LYSIMACHIA (*Tenella*) foliis ovatis acutiuſculis, pedunculis folio longioribus, caule repente. Lin. Sp. Plant. 148. *Looſtrife with oval acute-pointed leaves, foot-ſtalks longer than the leaf, and a creeping ſtalk.* Nummularia minor, purpuraſcente flore. C. B. P. 310. *Smaller Moneywort with a purpliſh flower.*

9. LYSIMACHIA (*Nemorum*) foliis ovatis acutis, floribus ſolitariis, caule procumbente. Hort. Cliff. 52. *Looſtrife with oval acute-pointed leaves, flowers growing ſingly, and a trailing ſtalk.* Anagallis lutea nemorum. C. B. P. 252. *Yellow Pimpernel of the woods.*

10. Lysimachia (*Quadrifolia*) foliis ſubquaternis, pedunculis verticillatis unifloris. Lin. Sp. Plant. 147. *Looſtriſe with leaves generally placed by fours, and foot-ſtalks placed in whorls round the ſtalks, each ſuſtaining a ſingle flower.* Lyſimachia lutea minor, foliis nigris punctatis notatis. C. B. P. 245. *Smaller yellow Looſtriſe with leaves marked with black ſpots.*

The firſt ſort grows by the ſide of ditches and rivers in many parts of England, ſo is not often admitted into gardens, becauſe the roots creep far in the ground, and ſend up ſtalks at a great diſtance, whereby it becomes often a troubleſome plant; otherwiſe for the variety of its flowers, it might deſerve a place in large gardens, eſpecially in moiſt places, where better things will not thrive. It riſes with upright ſtalks from two to three feet high, garniſhed with ſmooth ſpear-ſhaped leaves placed ſometimes by pairs oppoſite; at others there are three, and frequently four of theſe leaves placed round the ſtalk at each joint. The upper part of the ſtalk divides into ſeveral foot-ſtalks, which ſuſtain yellow flowers growing in a panicle; theſe have one petal which is deeply cut into five ſegments, ſpreading open. They appear in June and July, and are ſucceeded by roundiſh ſeed-veſſels, filled with ſmall ſeeds which ripen in the autumn. This is placed in the liſt of medicinal plants, but is not often uſed. If the roots of this plant are taken up from the places where it grows naturally in the autumn, and planted in a moiſt ſoil, they will thrive faſt enough without care.

The ſecond ſort grows naturally in the northern parts of England; this hath a perennial creeping root, which ſends up ſeveral erect ſtalks near a foot and a half high, garniſhed at every joint by two pretty long narrow leaves placed oppoſite, whoſe baſe ſits cloſe to the ſtalk; they are about three inches long, and more than half an inch broad toward their baſe, leſſening gradually to the end, which terminates in acute points; the foot-ſtalks of the flowers come out oppoſite on each ſide of the ſtalks; they are an inch long, ſuſtaining at their top a globular or oval thyrſe of yellow flowers, whoſe ſtamina are much longer than the petals. This flowers at the ſame time with the former ſort, but ſeldom produces ſeeds, for the roots creep ſo much as to render it barren. It is but ſeldom kept in gardens, for the ſame reaſon as the former is rejected; but thoſe who are deſirous to have it, may procure the roots and plant them in a moiſt ſoil, where it will ſoon ſpread.

The third ſort is a biennial plant, which was diſcovered by Dr. Tournefort in the Levant, from whence he ſent the ſeeds to the Royal Garden at Paris, where they ſucceeded, and many of the European gardens have from thence been furniſhed with it. This riſes with an upright ſtalk about a foot high, garniſhed with ſpear-ſhaped leaves ending in acute points; theſe are placed by pairs oppoſite; they are ſmooth, and of a lucid green. The flowers grow in a looſe ſpike, terminating the ſtalks; the flowers ſtand horizontally, ſpreading out on each ſide the ſtalk; they have longer tubes than the other ſpecies, and are of a purple colour. Theſe appear in June, and the ſeeds ripen in September, ſoon after which the plants decay.

It is propagated by ſeeds, which ſhould be ſown on a moderate hot-bed in the ſpring, often watering the ground to bring up the plants; and if the ſeaſon ſhould prove warm, the glaſſes of the hot-bed ſhould be ſhaded in the heat of the day; when the plants are up, they ſhould have a large ſhare of freſh air admitted to them in warm weather, to prevent their drawing up weak, and ſhould be frequently refreſhed with water. When they are fit to remove, they ſhould be each planted in a ſeparate pot, plunging them into a moderate hot-bed to forward their taking new root: after which they ſhould be gradually inured to bear the open air, into which they ſhould be removed by the beginning of June, where they may remain till October, when they ſhould be removed into a common frame, where they may be ſheltered from froſt in winter, but ſhould always enjoy the free air in mild weather. The ſpring following ſome of the plants ſhould be ſhaken out of the pots, and planted in borders; but a few of them ſhould be put into larger pots, where they may flower and ſeed: this is called Ephemerum by Linnæus, but is not ſo.

When the plants come up, they muſt have plenty of air admitted to them in warm weather, to prevent their drawing up weak; then they may be planted into the borders of the pleaſure-garden, where they will flower and produce ripe ſeeds the following ſummer.

The fourth ſort is an annual plant, which is too tender to riſe in the open air in this country, therefore the ſeeds ſhould be ſown on a moderate hot-bed in the ſpring, and the plants afterward treated in the ſame manner as hath been directed for the third ſort.

The fifth ſort was firſt brought from Canada, where it grows naturally; this hath a perennial creeping root, ſending up many erect ſtalks about two feet high, garniſhed with oblong, oblique, ſmooth leaves, placed oppoſite; they are veined on their under ſide, and end in acute points. The flowers are produced from the wings of the ſtalks, each ſitting upon a long ſlender foot-ſtalk; there are three or four of theſe ariſing from the ſhort branches, which come out on each ſide the ſtalk, at all the upper joints. The flowers are like thoſe of the firſt ſort, but ſmaller, and hang downward; theſe appear in June and July, but are ſeldom ſucceeded by any ſeeds in England. This ſort ſpreads and propagates by roots, in as great plenty as the firſt, and is equally hardy, ſo requires no other culture.

The ſixth ſort grows naturally in Spain, and was formerly titled by John Bauhin and others, Ephemerum; this hath a perennial root, from which ariſe ſeveral upright ſtalks upward of three feet high, garniſhed with narrow, ſmooth, ſpear-ſhaped leaves, which ſtand oppoſite, and at the baſe of theſe come out ſhort ſide branches, garniſhed with ſmaller leaves of the ſame ſhape. The flowers are produced in a long, cloſe, upright ſpike, at the top of the ſtalk; they are cut into five oval ſegments, which are white, ſpreading open, and the ſtamina ſtand out longer than the petal. It flowers in June, and the ſeeds ripen in autumn.

This is the fineſt ſpecies of this genus, and as the roots of it do not ſpread like thoſe of the other, ſo deſerves a place in the pleaſure-garden, where it is a very ornamental plant for ſhady borders. It loves a moiſt ſoil and a ſhady ſituation, where it will continue long in beauty. It may be propagated by parting the roots in autumn, but by this method it increaſes ſlowly; ſo that the only way to have it in plenty, is by ſowing the ſeeds: theſe ſhould be ſown upon an eaſt-aſpected border in autumn, ſoon after they are ripe, then the plants will come up the following ſpring; but thoſe which are ſown in the ſpring will not grow the ſame year. When the plants come up they ſhould be kept clean from weeds, and if they are too cloſe, ſome of them may be drawn out and tranſplanted on a ſhady border, which will give the remaining plants room to grow till autumn, when they may be tranſplanted into the borders of the flower-garden where they are deſigned to flower; after which they will require no other culture but to keep them clean from weeds, and dig the ground between them every ſpring.

The ſeventh ſort is commonly called Moneywort, or Herb Two-pence; this is a perennial plant, which grows naturally in moiſt ſhady places in moſt parts of England, ſo is not cultivated in gardens. The ſtalks of this trail upon the ground, and put out roots, by which it ſoon ſpreads to a great diſtance. The leaves are almoſt heart-ſhaped, and placed by pairs. The flowers come out ſingly from the ſide of the ſtalks; they are yellow, appearing in June and July.

The eighth ſort is a ſmall trailing plant, which grows upon bogs in moſſy places in moſt parts of England, but cannot be cultivated on dry ground. The ſtalks ſeldom are more than three or four inches long, and are terminated by three or four ſmall flowers, of a bright purple colour, growing in a bunch. This flowers in June, but is rarely planted in gardens.

The ninth ſort is a perennial plant with trailing ſtalks, which grow naturally in moiſt woods in moſt parts of England, ſo is not cultivated in gardens. The leaves ſtand oppoſite at each joint; they are ſmooth, oval, and acute-pointed. The flowers come out ſingly from the ſide of the ſtalk, upon long foot-ſtalks; they are yellow, and ſpread open like the flowers of Chickweed. This flowers in May and June, and the ſeeds ripen in autumn.

The tenth ſort grows naturally among Ruſhes and Reeds, by the rivers ſides in Holland; this hath a perennial creeping root like the firſt. The ſtalks riſe a foot high; they are ſlender, and are garniſhed by ſpear-ſhaped leaves an inch and a half long, and a quarter of an inch broad in the middle, placed ſometimes by pairs, at others by threes, and often four at each joint, ſurrounding the ſtalk. The flowers alſo come out at each joint, four of them ſtanding round the ſtalk in whorls, each having a diſtinct ſlender foot-ſtalk an inch long. The flowers are ſmall and yellow; they appear in June, and are ſometimes ſucceeded by ſeeds which ripen in autumn; it may be treated in the ſame manner as the firſt ſort, and is equally hardy.

LYSIMACHIA SILIQUOSA. See Epilobium.

LYTHRUM. Lin. Gen. Plant. 532. Salicaria. Tourn. Inſt. R. H. 253. tab. 129. *Willow Herb, or purple Looſtrife.*

The Characters are,

The flower hath a cylindrical ſtriated empalement of one leaf, indented at the brim in twelve parts, which are alternately ſmaller. It has ſix oblong blunt petals which ſpread open, whoſe tails are inſerted in the indentures of the empalement, and ten ſlender ſtamina the length of the empalement, the upper being ſhorter than the lower, terminated by ſingle riſing ſummits. In the center is ſituated an oblong germen, ſupporting an awl-ſhaped declining ſtyle, crowned by a riſing orbicular ſtigma. The germen afterward turns to an oblong acute capſule with two cells, filled with ſmall ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's eleventh claſs, intitled Dodecandria Monogynia, which includes thoſe plants whoſe flowers have twelve ſtamina and one ſtyle.

The Species are,

1. Lythrum (*Salicaria*) foliis oppoſitis cordato-lanceolatis, floribus ſpicatis dodecandris. Lin. Sp. Plant. 446. *Lythrum with heart ſpear-ſhaped leaves placed oppoſite, and flowers growing in ſpikes, having twelve ſtamina.* Salicaria vulgaris, purpurea, folis oblongis. Tourn. Inſt. R. H.. 253. *Common purple Willow Herb with oblong leaves.*
2. Lythrum (*Tomentoſum*) foliis cordato-ovatis, floribus verticillato-ſpicatis tomentoſis. *Lythrum with oval heart-ſhaped leaves, and flowers growing in whorly ſpikes, which are woolly.* Salicaria purpurea, foliis ſubrotundis. Tourn. Inſt. R. H. 253. *Purple Willow Herb with roundiſh leaves.*
3. Lythrum (*Hyſſopifolia*) foliis alternis linearibus, floribus hexandris. Hort. Upſal. 118. *Lythrum with linear alternate leaves, and flowers having ſix ſtamina.* Salicaria hyſſopi folio anguſtiore. Tourn. Inſt. R. H. 253. *Willow Herb with a narrow Hyſſop leaf.*
4. Lythrum (*Luſitanicum*) foliis lanceolatis ternis glabris, floribus ſpicatis decandris. *Lythrum with ſmooth ſpear-ſhaped leaves placed by threes, and flowers growing in ſpikes, which have ten ſtamina.* Salicaria Luſitanica, anguſtiore folio. Tourn. Inſt. R. H. 253. *Portugal Willow Herb with a narrower leaf.*
5. Lythrum (*Hiſpanicum*) foliis oblongo-ovatis infernè oppoſitis ſupernè alternis floribus hexandris. *Lythrum with oblong oval leaves placed oppoſite below, but above alternate, and flowers having ſix ſtamina.* Salicaria Hiſpanica, hyſſopifolia, floribus oblongis ſaturatè cæruleis. Tourn. Inſt. 253. *Spaniſh Willow Herb with a Hyſſop leaf, and oblong, deep, blue flowers.*
6. Lythrum (*Verticillatum*) foliis oppoſitis, ſubtus tomentoſis ſubpetiolatis, floribus verticillatis lateralibus. Lin. Sp. Plant. 446. *Willow Herb with oppoſite leaves, which are woolly on their under ſide, and flowers growing in whorls round the ſtalks.*
7. Lythrum (*Petiolatum*) foliis oppoſitis linearibus petiolatis, floribus dodecandris. Lin. Sp. Plant. 446. *Willow Herb with linear leaves placed oppoſite, having foot-ſtalks, and flowers with twelve ſtamina.*
8. Lythrum (*Lineare*) foliis oppoſitis linearibus, floribus oppoſitis hexandris. Lin. Sp. Plant. 447. *Willow Herb with linear oppoſite leaves, and flowers having ſix ſtamina, which are placed oppoſite.*
9. Lythrum (*Americanum*) foliis oblongo-ovatis infernè oppoſitis ſupernè alternis, floribus hexandris, caule erecto. *Willow Herb with oblong leaves placed oppoſite below, and above alternate, with flowers having ſix ſtamina and an erect ſtalk.* Salicaria Americana, hyſſopi folio latiore, floribus minimis. Houſt. MSS. *American Willow Herb with a broader Hyſſop leaf, and very ſmall flowers.*

The firſt ſort grows naturally by the ſide of rivers and ditches in moſt parts of England. It has a perennial root, from which come forth ſeveral upright angular ſtalks, which riſe from three to four feet high; they are of a purple colour, and are garniſhed with oblong leaves, placed ſometimes by pairs oppoſite, at others there are three leaves at each joint, ſtanding round the ſtalk. The flowers are produced in a long ſpike at the top of the ſtalk; they are of a fine purple colour, and make a fine appearance. This flowers in July, and the ſeeds ripen in autumn: although this plant is deſpiſed, becauſe it grows common, yet it merits a place in gardens better than many other which are propagated with care, becauſe they are more rare. It is eaſily cultivated by parting the roots in autumn, and ſhould be planted in a moiſt ſoil, where it will thrive and flower without any other care than the keeping it clean from weeds.

There is a variety of this with an hexangular ſtalk, and generally with three leaves at each joint; but this is only accidental, for the roots of this, when removed into a garden, come to the common ſort.

The ſecond ſort hath perennial roots like the firſt, from which come out upright branching ſtalks three feet high, garniſhed with oval heart-ſhaped leaves about one inch long, and three quarters of an inch broad; they are downy, and placed by threes round the ſtalk. The flowers are produced in long ſpikes at the top of the ſtalks, but they are diſpoſed in thick whorls, with ſpaces between each; they are of a fine purple colour, and appear at the ſame time with the former. This may be propagated in the ſame way as the firſt ſort, and is equally hardy.

The third ſort grows naturally in moiſt bogs in many parts of England, ſo is ſeldom admitted into gardens; this hath a perennial root, ſending up two or three branching ſtalks about a foot high, garniſhed with narrow leaves, placed alternate. The upper part of the ſtalk is garniſhed with flowers, which come out from the ſide ſingly at each joint, ſtanding cloſe to the baſe of the leaves; they are ſmall, and of a light purple colour, appearing in June, and the ſeeds ripen in autumn.

The fourth ſort grows naturally in Spain and Portugal, in moiſt places by the ſide of waters; this has a perennial root and ſtalks like the firſt, which ſeldom grow more than one foot high, garniſhed with narrower and ſhorter leaves than the firſt, which are ſmooth, and placed by threes round the ſtalk. The flowers grow in ſpikes at the top of the ſtalks; they are of a light purple colour, and appear in July. The ſeeds ripen in autumn. This ſort is hardy, and may be propagated in the ſame way as the firſt.

The fifth ſort grows naturally in Spain and Portugal, from both which countries I have received the ſeeds.

The root of this is perennial. The ſtalks are ſlender, not more than nine or ten inches long, ſpreading out on every ſide. The lower part of the ſtalks are garniſhed with oblong oval leaves, placed oppoſite. On the upper part of the ſtalks the leaves are narrower, and placed alternate. The flowers come out ſingly from the ſide of the ſtalks at each joint; they are larger than thoſe of the common ſort, and of a deeper purple colour, ſo make a fine appearance in July, when they are in beauty.

This ſort has never produced any ſeeds in England, and the ſevere froſt in 1740, killed all the plants here, ſince which time I have not ſeen any of them in the Engliſh gardens.

The ſixth ſort grows naturally in the northern parts of America; this riſes with a ſtiff branching ſtalk a foot and a half high, garniſhed with oblong leaves, which are downy, and placed oppoſite, ſtanding upon very ſhort foot-ſtalks. The flowers are produced in whorls round the ſtalks; they are of a pale purple colour, and appear in July; theſe are ſucceeded by capſules with two cells, filled with ſeeds which ripen in autumn.

The ſeventh ſort grows naturally in Virginia, from whence I received the ſeeds; this riſes with an upright woolly ſtalk near two feet high, garniſhed with linear leaves placed oppoſite, upon ſhort foot-ſtalks. The flowers come out from the wings of the ſtalks ſingly; they are ſmall, tubulous, and of a pale purple colour, ſo make no great appearance; theſe appear in July, and in warm ſeaſons only will perfect ſeeds; but the roots of this ſort will increaſe ſo faſt, as to render the propagating the plants by ſeeds unneceſſary, when once obtained.

The eighth ſort grows naturally in North America. It has a perennial root. The ſtalks are ſlender, about a foot high, garniſhed with linear leaves placed oppoſite, which are entire. The flowers come out ſingly from the wings of the leaves, on the upper part of the ſtalks; they are ſmall, white, and have ſix petals. The empalement is ſtreaked, and cut at the top into ſix parts, and the flower has ſix ſtamina. This flowers in June, and the ſeeds ripen in autumn.

The ninth ſort was diſcovered by the late Dr. Houſtoun at La Vera Cruz, growing in ſwamps, where the water had ſtagnated. This hath a ligneous root, from which ariſe two or three ſlender ſtalks upward of two feet high, garniſhed with oblong, oval, ſmooth leaves, which, on the lower part of the ſtalks are oppoſite, but thoſe on the upper part are narrow and alternate. The flowers come out from the wings of the leaves, on the upper part of the ſtalk ſingly; they are ſmall and white, having ſix petals and ſix ſtamina; theſe do not appear till the ſecond year from ſeed, and have not produced any good ſeeds in England.

This ſort is tender, ſo will not live in the open air in England. It is propagated by ſeeds, which ſhould be ſown in pots, and plunged into an old hot-bed the firſt ſeaſon; for the ſeeds never riſe the firſt year, unleſs they are ſown in autumn; the pots ſhould be ſheltered in winter, and the ſpring following placed on a hot-bed to bring up the plants; theſe muſt be treated in the ſame way as other tender plants from the ſame country.

All the other ſorts, when raiſed from ſeeds, ſhould be ſown in autumn, otherwiſe the ſeeds will remain a year in the ground, ſo that thoſe ſeeds which are brought from America, never grow the ſame year they are ſown; for which reaſon the ground ſhould not be diſturbed in which the ſeeds are ſown, but left till the following ſpring, when the plants will come up if the ſeeds were good.

MADDER. See Rubia Tinctorum.

MAGNOLIA. Plum. Nov. Gen. 38. tab. 7. Lin. Gen. Plant. 610. The Laurel-leaved Tulip-tree, vulgò.

The Characters are,

The empalement is compoſed of three oval concave leaves like petals, which ſoon fall away. The flower is compoſed of nine oblong blunt petals, which are concave. It hath a great number of ſhort ſtamina which are compreſſed, and inſerted into the germen, terminated by linear ſummits, adhering to every ſide of the ſtamina. It hath many oblong oval germina faſtened to the receptacle, ſupporting recurved, contorted, ſhort ſtyles, with longitudinal hairy ſtigmas. The germen afterward become oval cones, with roundiſh compreſſed capſules almoſt imbricated, having one cell, opening with two valves, incloſing one kidney-ſhaped ſeed, hanging by a ſlender thread from the ſcale of the cone.

This genus of plants is ranged in the ſeventh ſection of Linnæus's thirteenth claſs, intitled Polyandria Polygynia, which includes thoſe plants whoſe flowers have many ſtamina and ſtyles. If Father Plumier's figure of the ſection of his fruit is exact, his muſt be a different genus from this; for the ſeeds of his are repreſented within the fruit, lying round a column.

The Species are,

1. Magnolia (*Glauca*) foliis ovato-lanceolatis ſubtus glaucis. Lin. Sp. 755. *Magnolia with oval ſpear-ſhaped leaves, which are gray on their under ſide.* Magnolia lauri folio ſubtus albicante. Cateſb. Hiſt. Car. 1. p. 39. *Magnolia with a Bay leaf, which is whitiſh on the under ſide, commonly called Small Magnolia, or Laurel-leaved Tulip-tree.*
2. Magnolia (*Grandiflora*) foliis lanceolatis perſiſtentibus, caule erecto arboreo. Fig. Plant. tab. 172. *Magnolia with ſpear-ſhaped leaves which are evergreen, and an erect tree-like ſtalk.* Magnolia altiſſima, flore ingenti candido. Cateſb. Carol. 2. p. 61. *Talleſt Magnolia, with a very large white flower, commonly called Greater Magnolia, or Tulip-tree, with a Laurel leaf.*
3. Magnolia (*Tripetala*) foliis lanceolatis ampliſſimis annuis, petalis exterioribus dependentibus. *Magnolia with very large ſpear-ſhaped leaves which are annual, and the outer petals of the flower declining.* Magnolia ampliſſimo flore albo, fructu coccineo. Cateſb. Car. 2. p. 80. *Magnolia with a very large white flower and a ſcarlet fruit, commonly called Umbrella-tree.*
4. Magnolia (*Acuminata*) foliis ovato-lanceolatis acuminatis annuis, petalis obtuſis. *Magnolia with oval, ſpear-ſhaped, pointed leaves, which are annual, and obtuſe petals to the flower.* Magnolia flore albo, folio majore acuminato, haud albicante. Cateſb. Car. 3. p. 15. *Magnolia with a white flower, and a larger acute-pointed leaf, not whitiſh.*

The firſt ſort grows pretty common in Virginia, Carolina, and in moſt other parts of North America, where it is found in moiſt places, near brooks; this uſually grows about fifteen or ſixteen feet high, with a ſlender ſtem. The wood is white and ſpongy, the bark is ſmooth and white, the branches are garniſhed with thick ſmooth leaves, reſembling thoſe of the Bay, but are of an oval ſhape, and ſmooth on their edges, being white underneath. The flowers are produced in May and June at the extremity of the branches, which are white, compoſed of ſix petals which are concave, and have an agreeable ſweet ſcent. After theſe are paſt, the fruit increaſes in ſize to be as large as a Walnut with its cover, but of a conical ſhape, having many cells round the outſide, in each of which is lodged a flat ſeed, about the ſize of a Kidney-bean. This fruit is at firſt green, afterward red, and, when ripe, of a brown colour. The ſeeds, when ripe, are diſcharged from their cells, and hang by a ſlender thread.

In the natural places of its growth, there is a ſucceſſion of the flowers on the trees for two months or more, during which time the woods are perfumed with them; but all thoſe trees which have produced flowers in England, ſeldom have more than twelve or fourteen flowers upon each, which are of ſhort duration, and are not ſucceeded by others; the leaves of this ſort fall off in winter.

The young plants of this ſort frequently retain their leaves through the greateſt part of winter, and often do not fall off till the young ſhoots thruſt them off, which has occaſioned ſome perſons to believe the plants were evergreen; but when they are three or four years old, they conſtantly caſt their leaves by the beginning of November.

When theſe trees are tranſplanted from the places of their growth into dry ground, they make handſomer trees, and produce a greater number of flowers; this is to be underſtood of America, for in Europe they do not thrive ſo well in a dry ſoil as in a moiſt loamy land. The greateſt number of theſe trees, which are now growing in England, are at his Grace the Duke of Norfolk's, at Workſop Manor, in Nottinghamſhire.

The ſecond ſort grows in Florida and South Carolina, where it riſes to the height of eighty feet or more, with a ſtrait trunk upward of two feet diameter, having a large regular head: the leaves of this tree reſemble thoſe of the common Laurel, but are much larger, and of a ſhining green on their upper ſide, and, in ſome trees, they are of a ruſſet, or buff colour, on their under ſide; theſe leaves continue all the year, ſo that this is one of the moſt beautiful evergreen trees yet known. The flowers are produced at the end of the branches; they are compoſed of eight or ten petals, which are narrow at their baſe, but broad at their extremity, where they are rounded, and a little waved; theſe ſpread open wide, and are of a pure white colour. In the center is ſituated a great number of ſtamina and ſtyles, faſtened to one common receptaculum; theſe flowers are ſucceeded by oblong ſcaly cones in the places where it grows naturally, but the ſummers are not warm enough in England to produce any fruit to perfection, though ſome old plants do often form cones. Theſe trees in their native places of growth begin to produce their flowers in May, and continue a long time in flower, ſo that the woods are perfumed with their odour the greateſt part of ſummer; but thoſe which have flowered in England, ſeldom begin till the middle or latter end of June, and do not continue long in beauty. The largeſt tree of this kind, which I have met with in England, is in the garden of Sir John Colliton, of Exmouth, in Devonſhire, which has produced flowers for ſeveral years; there are alſo many pretty large plants of this ſort in the gardens of his Grace the Duke of Richmond, at Goodwood, in Suſſex, one of which has has produced flowers ſeveral years; and in the nurſery of Mr. Chriſtopher Gray, near Fulham, there is one very handſome plant, which has alſo produced many flowers ſeveral years.

As this ſort is a native of a warm country, it is a little impatient of cold, eſpecially while young, therefore the plants ſhould be kept in pots, and ſheltered in winter for ſome years, until they have acquired ſtrength, when they may be ſhaken out of the pots, and planted in the full ground, but they muſt be planted in a warm ſituation, where they may be defended from the ſtrong winds, and ſcreened from the north and eaſt, otherwiſe they will not live abroad.

There were a great number of young plants in England before the year 1739; but a great part of them were deſtroyed by that ſevere winter, and ſince then, there have been few good ſeeds ſent to England, ſo that there are not many of the plants at preſent to be ſold in the nurſeries; and as almoſt every perſon who is curious in gardening, is deſirous to have ſome of theſe beautiful trees in their gardens, the demand for them of late has greatly increaſed their value. If this tree can be ſo far naturalized as to endure the cold of our ſevereſt winters abroad, it will be one of the greateſt ornaments to our gardens; and this we may hope, will, in time, be effected, by diligent obſervation and care; for the time when theſe plants ſuffer moſt, is in autumn, by the early froſts; for the extremity of the ſhoots being then tender, as they are then generally growing freely, a ſmall froſt will pinch them, and afterward the whole ſhoot frequently decays; ſo that the plants ſhould be guarded againſt theſe early froſts, by covering their tops with mats until the ſhoots are hardened, after which time they will not be in ſo much danger of ſuffering; for I have conſtantly obſerved, that if theſe plants eſcape the early froſts of the autumn, they are ſeldom injured afterward: in the ſevere winter in the year 1739-40, I had a pretty large plant growing in the open air, which was killed down by the froſt, and I ſuppoſed was entirely deſtroyed, as there was not the leaſt appearance of life in the ſtem; ſo that after Midſummer I cut it down to the ground, but left the root remaining, which, to my great ſurprize, ſhot up again the year after. This I mention, to caution people from being too haſty in deſtroying plants after hard froſt, but to have them wait until there can be no hopes of their recovery.

The third ſort grows in Carolina pretty frequent, but in Virginia it is pretty rare; this uſually grows from ſixteen to twenty feet high, with a ſlender trunk; the wood is ſoft and ſpongy; the leaves of this tree are remarkably large, and are produced in horizontal circles, ſomewhat reſembling an umbrella, from whence the inhabitants of thoſe countries have given it the title of Umbrella-tree. The flowers are compoſed of ten or eleven white petals, which hang down without any order; the fruit is very like that of the former ſort; the leaves of this ſort drop off at the beginning of winter.

This tree is as yet very rare in Europe, but as it is propagated from ſeeds, we may hope to have it in greater plenty ſoon, if we can obtain good ſeeds from Carolina, for it is rarely met with in Virginia.

The fourth ſort is alſo very rare in England; there are but few of the plants at preſent here, nor is it very common in any of the habitable parts of America: ſome of theſe trees have been diſcovered by Mr. John Bartram, growing on the north branch of Suſquehannah river. The leaves of this tree are near eight inches long and five broad, ending in a point. The flowers come out early in the ſpring, which are compoſed of twelve white petals, ſhaped like thoſe of the ſecond ſort; the fruit of this tree is longer than thoſe of the other ſpecies, but in other reſpects agrees with them. The wood of this tree is of a fine grain, and an Orange colour.

All theſe ſorts are propagated by ſeeds, which muſt be procured from the places of their natural growth; theſe ſhould be put up in ſand, and ſent over to England as ſoon as poſſible; for if they are kept long out of the ground, they very rarely grow, therefore the ſeeds ſhould be ſown as ſoon as poſſible, when they arrive here.

Some years paſt I received a good quantity of theſe ſeeds from Carolina, which I ſowed in pots as ſoon as I received them, and plunged the pots into an old hot bed of tanners bark; and with this management

I raiſed a great number of plants, but from the ſeeds which have been lately brought over, there have been but few plants produced; whether the ſeeds were not perfectly ripe when they were gathered, or from what other cauſe this has happened, I cannot ſay, but it is certain the fault muſt be in the ſeeds, becauſe thoſe before-mentioned were differently ſown and managed by the ſeveral perſons who received them, and the ſucceſs was nearly alike every where.

There have been ſeveral plants of the firſt and ſecond ſort raiſed from layers, and ſome from cuttings; but theſe do not thrive ſo well as thoſe which come from ſeeds, nor will they grow to near the ſize of thoſe, ſo that it is much the beſt way to procure their ſeeds from America, and propagate them that way.

The firſt ſort frequently comes up well from ſeeds, but the young plants are very difficult to keep the two firſt years; for if they are expoſed much to the ſun, their leaves change yellow and the plants decay; ſo the beſt way is to keep the pots plunged in a moderate hot-bed, and ſhade them every day from the ſun with mats, giving them air in plenty when the weather is warm, and frequently refreſh them with water; during the winter ſeaſon they muſt be ſcreened from froſt, and in mild weather they muſt enjoy the free air, to prevent their growing mouldy, and they ſhould have but little wet in winter. With this management the plants may be trained up, and when they have acquired ſtrength, they may be planted in the open air, where they will thrive and flower, if they have a warm ſheltered ſituation.

The ſecond ſort is not ſo difficult to train up as the firſt, but in order to get them forward, it will be proper when they are removed out of the ſeed-pots, to plant them each into a ſeparate ſmall pot, filled with ſoft loamy earth, and plunge them into a gentle hot-bed of tanners bark, obſerving to ſhade them from the ſun, and admit proper air to them; but at Midſummer, if they are well rooted, they ſhould be inured to the open air gradually, and then placed in a ſheltered ſituation, where they may remain till autumn; but on the firſt approach of froſt, they ſhould be removed under ſhelter, otherwiſe the early froſts will pinch their tender ſhoots, which often occaſions their dying downward after. When the plants have got ſtrength, ſome of them may be turned out of the pots, and planted in the full ground in a warm ſheltered ſituation, but part of them ſhould be kept in pots, and ſheltered in the winter, to preſerve them, leſt, by ſevere froſt, the other ſhould be killed.

If the plants make good progreſs, they will be ſtrong enough to plant in the full ground in abour ſix or ſeven years from ſeeds. The time for removing or ſhifting theſe plants is in March, before they begin to ſhoot, which may ſometimes happen to be too ſoon to turn them out of the pots into the full ground, eſpecially if the ſeaſon proves late; but as there will be no danger in removing them out of the pots, the ball of earth being preſerved to their roots, ſo it is beſt to defer this till the month of April; but it will be neceſſary to harden thoſe plants which are intended to be planted out, by expoſing them to the air as much as poſſible before, which will keep the plants backward, and prevent their ſhooting; for if they make ſhoots in the green-houſe, thoſe will be too tender to bear the ſun, until they are by degrees hardened to it, and the leaſt froſt will greatly pinch them, and ſuch froſts frequently happen very late in the ſpring.

The two or three winters after theſe are planted out, it will be neceſſary to lay ſome mulch on the ſurface of the ground about their roots, as alſo to throw ſome mats over their heads, eſpecially at the beginning of the morning froſts in autumn, for the reaſons before given; but in doing this, the heads of the plant ſhould never be too cloſely covered up, leſt thereby the ſhoots ſhould grow mouldy, for that will certainly kill the leading buds of every ſhoot, and prove to the full as injurious to them as the froſt.

As the plants get ſtrength, they will be better able to endure the cold of our climate, though it will be proper to lay ſome mulch about their roots every winter; and, in very ſevere froſt, to cover their heads and ſtems.

It is the firſt ſort which requires the moſt care, being much tenderer than any of the other, for they will endure the cold very well, without much care, after they have acquired ſtrength; for as theſe loſe their leaves in the winter, the froſt will not have ſo much force upon them as of the firſt ſort, whoſe leaves are frequently tender toward the end of the ſhoots, eſpecially when they grow freely, or ſhoot late in the autumn.

MALLOW. See Malva.

MALLOW-TREE. See Lavatera.

MALOPE. Baſtard Mallow.

The Characters are,

The flower, which is ſhaped like that of the Mallow, hath a double empalement, the outer being compoſed of three heart-ſhaped leaves, and the inner is of one leaf cut into five ſegments; the flower is of one petal, divided into five parts at the bottom, where they are joined, but ſo near the bottom as to have the appearance of five petals. In the center ariſes the pointal, having a great number of ſtamina ſurrounding it, which are joined cloſely, and form a ſort of column. The pointal afterward becomes a fruit compoſed of many cells, which are collected into a head, in each of which is lodged a ſingle ſeed.

We have but one Species of this plant, viz.

Malope (*Malacoides*) foliis ovatis crenatis glabris. Lin. Hort. Cliff. 347. *Baſtard Mallow, with oval ſmooth leaves, which are notched.*

This plant was by Dr. Tournefort ſeparated from the Mallow, and made a diſtinct genus, by the title of Malacoides; but Dr. Linnæus has altered the title of this for Malope, being an enemy to all names which are compounded of oides.

The whole plant has greatly the appearance of the Mallow, but differs from it, in having the cells collected into a button, ſomewhat like a Blackberry; the branches ſpread, and lie almoſt flat upon the ground, extending themſelves a foot or more each way. The flowers are produced ſingly upon long foot-ſtalks, which ariſe from the wings of the leaves, which are in ſhape and colour like thoſe of the Mallow.

This is propagated by ſeeds, which ſhould be ſown in the place where they are deſigned to remain, for they do not bear tranſplanting well. If theſe ſeeds are ſown upon a warm border in Auguſt, the plants will frequently ſtand through the winter, and flower early the following ſeaſon, ſo that good ſeeds may be obtained; for thoſe which are ſown in the ſpring, rarely ripen ſeeds the ſame year in England; and theſe plants being large, are often deſtroyed in winter, unleſs they are ſheltered under a frame; it ſeldom continues longer than two or three years, ſo that young plants ſhould be annually raiſed.

MALPIGHIA. Plum. Nov. Gen. 46. tab. 36. Lin. Gen. Plant. 38. Barbadoes Cherry, vulgò.

The Characters are,

The flower hath a ſmall permanent empalement of five leaves, which are cloſed together. It hath two oval mellous glands, adhering to the ſmall leaves within and without. It has five kidney-ſhaped petals, which are concave, and ſpread open, having long narrow tails, and ten broad awl-ſhaped ſtamina, which are erect, terminated by heart-ſhaped ſummits. It has a ſmall roundiſh germen, ſupporting three ſlender ſtyles, crowned by obtuſe ſtigmas. The germen afterward turns to a large furrowed globular berry with one cell, incloſing three rough ſtony ſeeds, which are angular.

This genus of plants is ranged in the third ſection of Linnæus's tenth claſs, intitled Decandria Trigynia, which includes the plants whoſe flowers have ten ſtamina and three ſtyles.

The Species are,

1. Malpighia (*Glabra*) foliis ovatis integerrimis glabris, pedunculis umbellatis. Hort. Cliff. 169. *Malpighia with ſmooth, oval, entire leaves, and umbellated foot-ſtalks.* Ceraſus Jamaicenſis, fructu tetrapyreno. Hort. Amſt. 1. p. 145. *Jamaica Cherry with a fruit having four ſeeds, commonly called Barbadoes Cherry.*
2. Malpighia (*Punicifolia*) foliis ovato-lanceolatis, acuminatis, glabris, pedunculis umbellatis. *Malpighia with oval, ſpear-ſhaped, ſmooth leaves, ending in acute points, and umbellated foot-ſtalks.* Malpighia mali punici facie. Plum. Nov. Gen. 46. *Malpighia with the appearance of Pomegranate.*
3. Malpighia (*Incana*) foliis lanceolatis ſubtus incanis, pedunculis umbellatis alaribus. *Malpighia with ſpear-ſhaped leaves, hoary on their under ſide, and umbellated foot-ſtalks, proceeding from the wings of the ſtalk.*
4. Malpighia (*Urens*) foliis cordato-lanceolatis, ſetis decumbentibus rigidis, racemis lateralibus. *Malpighia with ſpear heart-ſhaped leaves, having rigid declining briſtles, and bunches of flowers proceeding from the ſides of the ſtalks.* Malpighia latifolia, folio ſubtus ſpinoſo. Plum. Nov. Gen. 46. *Broad-leaved Malpigha, with ſpines growing on the under ſide of the leaf.*
5. Malpighia (*Nitida*) foliis ovatis acutis glabris, pedunculis umbellatis alaribus terminalibuſque. *Malpighia with oval, ſmooth, acute-pointed leaves, and umbellated foot-ſtalks, proceeding from the ſides and at the ends of the branches.*
6. Malpighia (*Paniculata*) foliis oblongo-cordatis acuminatis glabris, pedunculis paniculatis, alaribus terminalibuſque. *Malpighia with oblong, heart-ſhaped, ſmooth leaves, ending in acute points, and paniculated foot-ſtalks proceeding from the ſides and ends of the branches.* Apocynum fruticoſum, folio oblongo acuminato, floribus racemoſis. Sloan. Cat. 89. *Shrubby Dogſbane with an oblong acute-pointed leaf, and flowers growing in cluſters.*
7. Malpighia (*Anguſtifolia*) foliis lineari-lanceolatis, ſetis decumbentibus rigidis, pedunculis unbellatis alaribus. *Malpighia with linear ſpear-ſhaped leaves, rigid declining briſtles, and foot-ſtalks having umbels of flowers proceeding from the ſides of the branches.* Malpighia anguſtifolia, folio ſubtus ſpinoſo. Plum. Nov. Gen. 46. *Narrow-leaved Malpighia with ſpines under the leaves.*
8. Malpighia (*Illicifolia*) foliis lanceolatis dentato-ſpinoſis ſubtus hiſpidis. Lin. Sp. Plant. 426. *Malpighia with ſpear-ſhaped leaves, indented and prickly, whoſe under ſides are ſet with ſpiny hairs.* Malpighia anguſtis & acuminatis aquifolii foliis. Plum. Nov. Gen. 46. *Malpighia with narrow and acute-pointed Holly leaves.*
9. Malpighia (*Lucida*) foliis oblongo-ovatis obtuſis glabris, pedunculis racemoſis alaribus. *Malpighia with oblong oval leaves, which are obtuſe and ſmooth, and branching foot-ſtalks of flowers proceeding from the ſides of the branches.*
10. Malpighia (*Coccigrya*) foliis ſubovatis dentato-ſpinoſis, pedunculis unifloris. *Malpighia with leaves nearly oval, indented, and prickly, and foot-ſtalks with one flower.* Malpighia humilis, ilicis cocci-glandiferæ foliis. Plum. Nov. Gen. 46. *Low Malpighia with leaves like the Kermes Oak.*

The firſt ſort is commonly cultivated in the Weſt-Indies for the ſake of its fruit; this tree uſually grows to the height of ſixteen or eighteen feet, having a ſlender ſtem, covered with a light brown bark. The leaves are produced oppoſite; they are oval, ſmooth, ending in acute poins, and continue all the year. The flowers are produced in bunches upon pretty long foot-ſtalks, which come out from the ſide and at the end of the branches; theſe are compoſed of five roundiſh petals, which are of a Roſe colour, joined at their baſe. The flowers are ſucceeded by red fruit, ſhaped like thoſe of the ſmall wild Cherry, and of the ſame ſize, having ſeveral furrows, each incloſing four angular furrowed ſtones, ſurrounded by a thin pulp, which has an agreeable acid flavour; the fruit of this often ripens in England.

The ſecond ſort grows naturally in Jamaica; this riſes with a ſhrubby ſtalk ten or twelve feet high, dividing into ſeveral ſlender ſpreading branches, covered with a light brown bark, garniſhed with oval, ſpear-ſhaped, ſmooth leaves placed oppoſite, ending in acute points. The flowers are produced in ſmall umbels at the end of the branches, upon ſhort foot-ſtalks; they are of a pale Roſe colour, and compoſed of five obtuſe concave petals which are indented, having long narrow tails, by which they are joined; theſe ſpread open, and in the center is ſituated the roundiſh germen, ſupporting three ſtyles, attended by ten ſtamina which ſpread aſunder. The germen afterward turns to a roundiſh pulpy berry with many furrows, red when ripe, incloſing three or four hard angular ſeeds. The fruit of this ſort is eaten by the inhabitants of the iſles in America.

The third ſort grows naturally at Campeachy, from whence it was ſent me by the late Mr. Robert Millar. This riſes with a ſtrong woody ſtalk eighteen or twenty feet high, dividing into many branches, covered with a brown ſpotted bark, garniſhed with ſpear-ſhaped leaves placed oppoſite, which are hoary on their under ſide. The flowers come out in umbels from the ſide of the branches; they are of a Roſe colour, and are ſucceeded by oval channelled fruit, like thoſe of the former ſort.

The fourth ſort grows naturally in Jamaica, from whence the late Dr. Houſtoun ſent me the ſeeds. This riſes with a woody ſtalk from fifteen to eighteen feet high, dividing into many pretty ſtrong branches, which are furrowed, and covered with a brown bark. The leaves are from three to four inches long, and one broad at their baſe, where they are rounded in form of a heart, leſſening gradually to the point; they are covered on their under ſides with ſtinging briſtly hairs ſo cloſely, as to render it very troubleſome to handle them, for theſe hairs faſten themſelves into the fleſh, and are difficult to get out again. The flowers are produced in umbels from the ſide of the branches; they are of a light purple colour, and ſhaped like thoſe of the other ſpecies; they are ſucceeded by oval furrowed fruit like that of the former ſort. This is called in the Weſt-Indies, Couhage, or Cowitch Cherry.

The fifth ſort grows naturally at Carthagena in New Spain, from whence the late Dr. Houſtoun ſent me the ſeeds. This riſes with a ſhrubby ſtalk about ten feet high, covered with a light brown ſpotted bark, branching out regularly at the top on every ſide; the leaves are oval, ſmooth, and end in acute points, ſtanding oppoſite, of a light green on the upper ſide, but paler on the under. The flowers come out from the ſide of the ſtalks in ſmall umbels, ſtanding erect; the foot-ſtalks of the umbels are ſcarce an inch long. They are of a pale bluſh colour, ſhaped like thoſe of the former ſorts; theſe are ſucceeded by roundiſh furrowed berries with a red ſkin, covering three hard angular ſeeds.

The ſixth ſort grows naturally in Jamaica, from whence the late Dr. Houſtoun ſent the ſeeds to England. This riſes with ſeveral ſlender ſhrubby ſtalks from five to ſix feet high, garniſhed with oblong heart-ſhaped leaves, four inches long and one inch and a quarter broad at the baſe, where they are rounded in two heart-ſhaped lobes, gradually diminiſhing to the point; they are ſmooth, and of a pale yellowiſh green, placed oppoſite. The flowers are produced in looſe panicles from the ſide and at the end of the branches; they are of a light purple colour, ſhaped like thoſe of the other ſpecies, but ſmaller; the fruit is more pointed, and not ſo much furrowed.

The ſeventh ſort was ſent me from the iſland Barbuda: this riſes with a ſhrubby ſtalk ſeven or eight feet high, covered with a bright purpliſh bark which is ſpotted and furrowed, dividing toward the top into ſeveral ſmaller branches, garniſhed with narrow ſpear-ſhaped leaves, about two inches long and a quarter of an inch broad, of a lucid green on their upper ſide, but of a ruſſet brown on their under, where they are cloſely armed with ſtinging briſtles, which faſten themſelves into the fleſh or clothes of thoſe who touch them; theſe leaves are placed oppoſite. The flowers are produced from the ſide and at the end of the branches in ſmall umbels; they are of a pale purple colour, of the ſame form of the other ſpecies, but ſmaller; and are ſucceeded by ſmall, oval, furrowed fruit, of a dark purple colour when ripe.

The eighth ſort was ſent me from the iſland Berbuda in the Weſt-Indies, where it grows naturally. This riſes with a ſtrong woody ſtem from fifteen to twenty feet high, dividing into many ſpreading branches, covered with a gray bark, garniſhed with oblong oval leaves of a firm conſiſtence; they are about an inch long, and half an inch broad, rounded at their ends, of a lucid green, and placed oppoſite. The flowers come out from the ſide, and alſo at the end of the branches, upon pretty long foot-ſtalks, which branch in form of a racemus, or long bunch. They are of the ſame form with thoſe of the other ſpecies, but vary in their colour, ſome of them being of a bright red, and others of an Orange colour in the ſame bunch; theſe are ſucceeded by ſmall oval berries, which are leſs furrowed than thoſe of the other ſpecies, and, when ripe, change to a dark purple colour.

The ninth ſort grows naturally in the iſland of Cuba, where the late Dr. Houſtoun found it in plenty. This riſes with a ſhrubby ſtalk to the height of ſeven or eight feet, ſending out branches the whole length, which are covered with a gray bark, garniſhed with narrow prickly leaves like thoſe of the Holly, which have many ſtinging briſtles on their under ſide. The flowers are produced in ſmall cluſters from the ſide of the branches, they are of a pale bluſh colour, and ſhaped like thoſe of the other ſpecies, but ſmaller; the fruit is more pointed than thoſe of the common ſort, and turns to a dark purple colour when ripe.

The tenth ſort grows naturally near the Havanna, from whence the late Dr. Houſtoun ſent the ſeeds. This is a very low ſhrub, ſeldom riſing more than two or three feet high; the ſtalk is thick and woody, as are alſo the branches, which come out on every ſide from the root upward; they are covered with a rough gray bark, garniſhed with lucid leaves half an inch long, and almoſt as much broad; they appear as if cut at their ends, where they are hollowed in, and the two corners riſe like horns ending in a ſharp thorn, as do alſo the indentures on the ſides. The flowers come out from the ſide of the branches, upon foot-ſtalks an inch long, each ſuſtaining one ſmall pale bluſh flower, of the ſame form with thoſe of the other ſpecies; the fruit is ſmall, conical, and furrowed, changing to a purple red colour when ripe.

There are two other ſpecies of this genus, which have been lately introduced from America, but as neither of them have yet flowered here, ſo I have not enumerated them; and if thoſe warm parts of America were ſearched by perſons of ſkill, there might be many more ſpecies diſcovered; for from a large number of imperfect ſpecimens which were ſent me from the Spaniſh Weſt-Indies, I have ſelected many which have the appearance of the other ſpecies of this genus, but as they are without flowers or fruit, they cannot be aſcertained.

The fruit of ſeveral of the ſpecies here mentioned, are promiſcuouſly gathered and eaten by the inhabitants of the countries where they naturally grow; but the firſt ſort is cultivated in ſome of the iſlands for its fruit, though that is but indifferent: the pulp which ſurrounds the ſtones is very thin, but has a pleaſant acid flavour, which renders it agreeable to the inhabitants of thoſe warm countries, where, to ſupply the want of thoſe Cherries which are cultivated in Europe, they are obliged to eat the fruit of theſe ſhrubs.

Theſe plants are preſerved in the gardens of thoſe perſons who are ſo curious in botanical ſtudies, as to erect hot-houſes for maintaining foreign plants: and where there are ſuch conveniencies, theſe plants deſerve a place; becauſe they retain their leaves all the year, and commonly continue flowering from December to the end of March, when they make a fine appearance at a ſeaſon, when there is a ſcarcity of other flowers, and many times they produce ripe fruit here. Thoſe ſorts whoſe leaves are armed with ſtinging briſtles, like the Cowitch, are the leaſt worthy of a place in ſtoves, becauſe they are ſo troubleſome to handle, nor do their flowers make ſo good an appearance as many of the other ſorts. The tenth ſort is the moſt valuable for its flowers, which are produced in larger bunches than thoſe of any of the other, and there being flowers of different colours in the ſame bunches, they make a fine variety; and this ſort grows more like a tree than the others, the leaves are alſo of a ſtronger conſiſtence and of a lucid green.

As theſe plants are natives of the warmeſt parts of America, they will not live through the winter in England, unleſs they are preſerved in a warm ſtove; but when the plants have obtained ſtrength, they may be expoſed in the open air in a warm ſituation, from the middle or latter end of June, till the beginning of October, provided the weather continues ſo long mild; and the plants ſo treated, will flower much better than thoſe which are conſtantly kept in a ſtove.

They are all propagated by ſeeds, which muſt be ſown upon a good hot-bed in the ſpring; and when the plants are fit to tranſplant, they muſt be each put into a ſeparate ſmall pot filled with rich earth, and plunged into a hot-bed of tanners bark, and muſt be treated in the ſame manner as hath been directed for other tender plants of the ſame country; and for the two firſt winters, it will be proper to keep them in the bark-bed in the ſtove; but afterward they may be placed upon ſtands in the dry ſtove in winter, where they may be kept in a temperate warmth, in which they will thrive much better than in a greater heat; theſe muſt be watered two or three times a week, when they are placed in the dry ſtove, but it muſt not be given to them in large quantities.

MALT-DUST is accounted a great enricher of barren ground; it contains in it a natural heat and ſweetneſs, which gives the earth whereon it is laid a proper fermentation, as thoſe who live in malting countries have found by experience.

Some are of opinion, that there is not a greater ſweetener than Malt-duſt, where the grounds are natural clay, and have contracted a ſourneſs and auſterity, whether by reaſon of its having lain long untilled and unexpoſed to the air, or by reaſon of water having ſtood long thereon.

MALVA. Tourn. Inſt. R. H. 94. tab. 23. Lin. Gen. Plant. 751. [ſo called of μαλακίζω, or μαλάσσω, to ſoften, becauſe it is good to ſoften the belly.] Mallows; in French, *Mauve*.

The CHARACTERS are,

The flower has a double empalement; the outer is compoſed of three ſpear-ſhaped leaves, and is permanent; the inner is of one leaf, cut into five broad ſegments at the brim. The flower is, according to Tournefort, Ray, &c. of one petal; but according to Linnæus, it has five; they are joined at the baſe, and ſpread open, and fall off joined. It has a great number of ſtamina which coaleſce at bottom in a cylinder, but ſpread open above, and are inſerted in the petal, terminated by kidney-ſhaped ſummits. In the center is ſituated an orbicular germen ſupporting a ſhort cylindrical ſtyle, with many briſtly ſtigmas the length of the ſtyle. The empalement afterward turns to ſeveral capſules, which are joined in an orbicular depreſſed head faſtened to the column, opening on their inſide, each containing one kidney-ſhaped ſeed.

This genus of plants is ranged in the fifth ſection of Linnæus's ſixteenth claſs, intitled Monodelphia Polyandria, which contains thoſe plants whoſe flowers have many ſtamina joined with the ſtyle in one body.

The Species are,

1. Malva (*Sylveſtris*) caule erecto herbaceo, foliis ſeptem lobatis acutis pedunculis petioliſque piloſis. Lin. Sp. Plant. 969. *Mallow with an erect herbaceous ſtalk, with ſeven acute lobes to the leaves, and hairy foot-ſtalks both to the leaves and flowers.* Malva ſylveſtris, folio ſinuato. C. B. P. 314. *Wild Mallow with a ſinuated leaf.*
2. Malva (*Rotundifolia*) caule proſtrato, foliis cordato-orbiculatis obſoletè quinquelobis, pedunculis fructiferis declinatis. Lin. Sp. 969. *Mallow with proſtrate ſtalks, roundiſh heart-ſhaped leaves with five obſolete lobes, and the foot-ſtalks of the fruit declining.* Malva vulgaris, flore minore, folio rotundo. J. B. 2. p. 949. *Common Mallow with a ſmall flower and a round leaf.*
3. Malva (*Orientalis*) annua, caule erecto herbaceo, foliis lobatis obtuſis & crenatis. *Annual Mallow with an erect herbaceous ſtalk, and obtuſe lobed leaves which are crenated.* Malva orientalis erectior, flore magno ſuavè rubente. Tourn. Cor. 3. *Eaſtern Mallow with a more upright ſtalk, and a large, ſoft, red flower.*
4. Malva (*Criſpa*) caule erecto, foliis angulatis criſpis, floribus axillaribus glomeratis. Lin. Sp. 970. *Mallow with an erect ſtalk, angular curled leaves, and flowers in cluſters on the ſide of the ſtalks.* Malva foliis criſpis. C. B. P. 315. *Furbelowed Mallow.*
5. Malva (*Verticillata*) caule erecto, foliis angulatis, floribus axillaribus glomeratis ſeſſilibus, calycibus ſcabris. Vir. Cliff. 356. *Mallow with an erect ſtalk, angular leaves, and flowers growing in whorls at the wings of the ſtalks.*
6. Malva (*Chinenſis*) annua, caule erecto herbaceo, foliis ſuborbiculatis obſoletè quinquelobatis, floribus confertis alaribus ſeſſilibus. *Annual Mallow with an erect, herbaceous, ſingle ſtalk, leaves almoſt round, with five indented lobes, and flowers growing in cluſters, which ſit cloſe to the ſtalks.* Malva Sinenſis erecta, floſculis albis minimis. Boerh. Ind. alt. *Upright annual China Mallow, with very ſmall white flowers.*
7. Malva (*Cretica*) caule erecto ramoſo hirſuto, foliis angulatis, floribus alaribus pedunculis brevioribus. *Mallow with an erect, branching, hairy ſtalk, angular leaves, and flowers proceeding from the wings of the ſtalks, which grow upon ſhorter foot-ſtalks.* Malva Cretica annua altiſſima, flore parvo ad alas umbellato. Tourn. Cor. 2. *Talleſt annual Mallow of Crete, with ſmall flowers growing in umbels on the ſides of the ſtalk.*
8. Malva (*Peruviana*) caule erecto herbaceo, foliis lobatis, ſpicis ſecundis axillaribus ſeminibus denticulatis. Lin. Sp. Plant. 968. *Mallow with an erect herbaceous ſtalk, leaves having lobes, and ſpikes of flowers in fruitful cluſters proceeding from the ſides of the ſtalks, and indented ſeeds.*
9. Malva (*Alcea*) caule erecto, foliis multipartitis ſcabriuſculis. Hort. Cliff. 347. *Mallow with an erect ſtalk, and rough leaves divided into many parts.* Alcea tenuifolia criſpa. J. B. 2. 953. *Narrow-leaved curled Vervain Mallow.*
10. Malva (*Moſchata*) foliis radicalibus reniformibus inciſis, caulinis quinque partitis pinnato-multifidis. Hort. Upſal. 202. *Mallow with kidney-ſhaped lower leaves which are cut, and thoſe on the ſtalks divided into five parts, ending in winged points.* Alcea folio rotundo laciniato. C. B. P. 316. *Round cut-leaved Vervain Mallow.*
11. Malva (*Ægyptia*) foliis palmatis dentatis, corollis calyce minoribus. Lin. Sp. Plant. 690. *Mallow with hand-ſhaped indented leaves, and petals leſs than the empalement.* Alcea Ægyptia, geranii folio. Juſſ. *Egyptian Vervain Mallow with a Crane's-bill leaf.*
12. Malva (*Bryonifolia*) foliis palmatis ſcabris, caule tomentoſo fruticoſo, pedunculis multifloris. Prod. Leyd. 356. *Mallow with rough hand-ſhaped leaves, a ſhrubby woolly ſtalk, and foot-ſtalks with many flowers.* Althæa fruteſcens bryoniæ folio. C. B. P. 316. *Shrubby Vervain Mallow with a Briony leaf.*
13. Malva (*Tournefortia*) foliis radicalibus quinque partitis, trilobis linearibus, pedunculis folio caulino longioribus, caule procumbente. Amœn. Acad. 4. p. 283. *Mallow with cut leaves having three lobes, which are linear, and a declining ſtalk.* Alcea maritima Galloprovincialis, geranii folio. Tourn. Inſt. 98. *Maritime Vervain Mallow of Provence, with a Crane's-bill leaf.*
14. Malva (*Capenſis*) foliis ſubcordatis laciniatis hirſutis, caule arboreſcente. *Mallow with hairy cut leaves, almoſt heart-ſhaped, and a tree-like ſtalk.* Malva Africana fruteſcens, flore rubro. Hort. Amſt. 2. p. 171. *African ſhrubby Mallow with a red flower.*
15. Malva (*Americana*) foliis cordatis crenatis, floribus lateralibus ſolitariis, terminalibus ſpicatis. Prod. Leyd. 359. *Mallow with heart-ſhaped crenated leaves, and flowers growing ſingly from the ſides of the ſtalks, and in ſpikes at the top.* Althæa Americana, pumila, flore luteo ſpicato. Breyn. Cent. 124. *Low American Marſhmallow, with a yellow ſpiked flower.*

The two firſt ſorts are found wild in moſt parts of England, ſo are rarely cultivated in gardens. The firſt is the ſort commonly uſed in medicine, with which the markets are ſupplied by the herbfolks, who gather it in the fields. Theſe are both ſo well known, as to need no deſcription. There is a variety of the firſt with white flowers, which continues the ſame from ſeeds; but as it only differs in the colour of the flower, ſo it cannot be reckoned a diſtinct ſpecies.

The third ſort was diſcovered by Dr. Tournefort in the Levant, this is an annual plant with an erect ſtalk; the flowers are larger than thoſe of the common ſort, and are of a ſoft red colour. This is preſerved in ſome curious gardens for the ſake of variety.

The fourth ſort is annual; this riſes with an upright ſtalk four or five feet high; the leaves are curled on their edges, for which variety it is preſerved in gardens.

The fifth ſort was diſcovered firſt by Dr. Tournefort, and afterward by Dr. Sherard, in the Levant, who ſent the ſeeds to ſeveral gardens, where the plants have produced flowers and ſeeds; which having ſcattered in thoſe gardens ſo plentifully, as to become as common as our native ſorts.

The ſixth ſort was formerly ſent from China as a pot-herb, and hath been cultivated in ſome curious gardens in England; though it is not likely to obtain here as an eſculent plant, ſince we have many others which are preferable to it for that purpoſe. This is an annual plant, which will propagate itſelf faſt enough, provided it be permitted to ſcatter its ſeeds, when they ſeldom fail to grow, and are often very troubleſome when they have gotten poſſeſſion of the ground.

The ſeventh ſort grows naturally in Crete; this plant is annual, the ſtalks riſes rather higher than that of our common Mallow, and the branches extend farther, and are in greater plenty; the leaves are angular, and the flowers ſtand on ſhort foot-ſtalks. This will be very common, provided the ſeeds are permitted to ſcatter.

The eighth ſort grows naturally in Peru, from whence the ſeeds were ſent to the Royal Garden at Paris, by Mr. Joſeph de Juſſieu. This is an annual plant, riſing with an upright branching ſtalk near two feet high, garniſhed with broad hairy leaves, having three lobes. The flowers grow in ſpikes from the wings of the ſtalks; they are ſmall, of a pale blue, and ſet very cloſely on the ſpikes. Theſe appear in June, and are ſucceeded by ſeeds, which, if permitted to ſcatter, will come up plentifully the following ſpring without care.

The ninth ſort is the common Vervain Mallow, which is found growing naturally near London. It is a biennial plant; the ſtalks riſe higher than thoſe of the former, the leaves are cut into obtuſe lobes which are indented. The flowers are large, appearing in June and July, and the ſeeds ripen in autumn.

The tenth ſort differs from the ninth, in having taller hairy ſtalks, and the leaves being kidney-ſhaped, and finely cut into narrow ſegments. This grows naturally in the middle counties of England, and about Paris.

The eleventh ſort was ſent from Egypt to the Royal Garden at Paris, and hath ſince been communicated to many other gardens. This is an annual plant, whoſe ſtalks are about a foot long; they are ſmooth, and decline toward the ground. The leaves ſtand upon pretty long foot-ſtalks, they are ſhaped like a hand, having five diviſions which join at their baſe to the foot-ſtalk, and are indented on their ſides. The flowers come out ſingle from the wings of the ſtalk, and at the top in cluſters; they have pretty large acute empalements; the flowers are ſmall, and of a pale blue colour. Theſe appear in June, and the ſeeds ripen in autumn.

The twelfth ſort grows naturally in Spain; this riſes with a ſhrubby woolly ſtalk four or five feet high, ſending out branches on every ſide, garniſhed with angular woolly rough leaves; the foot-ſtalks ariſe from the wings of the leaves, each ſupporting four or five flowers of a bright purple colour, ſhaped like thoſe of the common Mallow, which appear in July, and the ſeeds ripen in autumn. This ſort ſeldom continues more than two or three years, but if the ſeeds are permitted to ſcatter, young plants will come up the following ſpring.

The thirteenth ſort grows naturally in the ſouth of France; this is an annual plant, which has ſome reſemblance of the former, but the ſtalks are longer and more branched; the leaves are cut into five obtuſe lobes almoſt to the bottom, and theſe are deeply cut on their ſide. The flowers ſtand upon very long foot-ſtalks; the empalement of the flower is large, prickly and acute-pointed; the flowers are blue, and larger than thoſe of the other ſort. It flowers and ripens its ſeeds about the ſame time.

The fourteenth ſort grows naturally at the Cape of Good Hope; this riſes with a woody ſtalk ten or twelve feet high, ſending out branches from the ſide the whole length; the ſtalks and branches are cloſely covered with hairs, and are garniſhed with hairy leaves, which are indented on the ſides, ſo as to have the appearance of a trilobate leaf; theſe on the young plants are three inches long and two broad at their baſe, but as the plants grow older, they are ſcarce half that ſize. The flowers come out from the ſide of the branches, upon foot-ſtalks an inch long; they are of a deep red colour, and ſhaped like thoſe of the common Mallow, but are ſmaller. This plant continues flowering great part of the year, which renders it valuable.

There are two other varieties of this plant, which have been mentioned by ſome authors as diſtinct ſpecies. The firſt is, Alcea Africana fruteſcens, groſſulariæ folio ampliore, unguibus florum atro-rubentibus. Act. Phil. 1729. *Shrubby African Vervain Mallow, with a larger Gooſeberry leaf, and the bottoms of the flower of a dark red.* The other is, Alcea Africana fruteſcens, folio groſſulariæ flore parvo rubro. Boerh. Ind. alt. 1. 271. *Shrubby African Vervain Mallow, with a Gooſeberry leaf, and a ſmall red flower.* The leaves of the laſt appear very different from either of the other, being deeply divided into three lobes, which are alſo deeply indented, ſo that any perſon upon ſeeing it would ſuppoſe it to be a different ſpecies; but I have frequently raiſed all theſe, with ſome other intermediate varieties, from the ſeeds of one plant.

This plant is eaſily propagated by ſeeds, which, if ſown in a common border in the ſpring, the plants will come up; but as it is too tender to live abroad in the winter, ſo when the plants are three or four inches high, they ſhould be each planted into a ſeparate pot of light freſh earth, placing them in the ſhade till they have taken freſh root; then they may be removed to a ſheltered ſituation, intermixing them with other hardy exotic plants, where they may remain till autumn; when the froſt comes on they ſhould be removed into the green-houſe, and afterward treated in the ſame way as the hardy plants from the ſame country, always allowing them plenty of free air in mild weather.

The fifteenth ſort grows naturally in moſt of the iſlands in the Weſt-Indies. This is an annual plant, which riſes about a foot high, ſending out a few ſhort branches from the ſide, which are woolly, and garniſhed with heart-ſhaped woolly leaves which are crenated on their edges, and are placed alternately upon pretty long foot-ſtalks. The flowers are produced ſingly from the ſide of the ſtalk, and in a cloſe ſpike at the top; they are ſmall, and of a pale yellow colour. They appear in July, and the ſeeds ripen in autumn.

This is propagated by ſeeds, which muſt be ſown upon a hot-bed in the ſpring; and when the plants are fit to remove, they ſhould be each planted in a ſeparate ſmall pot filled with light freſh earth, and plunged into a new hot-bed, ſhading them until they have taken freſh root; then they muſt have free air admitted to them in proportion to the warmth of the ſeaſon, and the latter end of June they may be placed in the open air in a ſheltered ſituation, where they will flower and produce ripe ſeeds.

The ſeeds of the other ſpecies ſhould be ſown the end of March, upon a bed of freſh light earth, and when the plants are up three or four inches high, they ſhould be tranſplanted where they are deſigned to be continued, allowing them a good diſtance; for if they are planted too cloſe, they do not appear ſo well; but they are beſt when intermixed with other flowers of the ſame growth, where they afford an agreeable variety.

Theſe ſeeds may alſo be ſown in Auguſt, for the plants will endure the greateſt cold of our climate, if placed on a dry ſoil, and will grow larger, and flower ſooner than thoſe ſown in the ſpring; or if the ſeeds are permitted to ſcatter, they will come up as the former ſorts, and thrive equally well.

MALVA ARBOREA. See LAVATERA.

MALVA ROSEA. See ALCEA.

MALUS. The Apple-tree.

The CHARACTERS are,

The empalement of the flower is of one leaf, cut into five ſegments. The flower conſiſts of five leaves, which expand in form of a Roſe, whoſe tails are inſerted into the empalement. The fruit is hollowed about the foot-ſtalk, is for the moſt part roundiſh, and umbellated at the top; it is fleſhy, and divided into five cells or partitions, in each of which is lodged one oblong ſeed.

Dr. Linnæus has joined the Pear, Apple, and Quince together, making them all of the ſame genus, and has reduced all the varieties of each to one ſpecies. The Apple he diſtinguiſhes by the title of Pyrus foliis ſerratis, pomis baſi concavis. Hort. Cliff. i. e. *Pear with ſawed leaves, and the Apple hollow at the baſe.* But where the fruit is admitted as a diſtinguiſhing character of the genus, the Apple ſhould be ſeparated from the Pear, this diſtinction being founded in nature; for theſe fruits will not take by budding or grafting upon each other, though it be performed with the utmoſt care. Indeed I have ſometimes ſucceeded ſo far, as to have the bud or graft of an Apple ſhoot when grafted on a Pear, but they ſoon decayed, notwithſtanding all poſſible care was taken of them; therefore I ſhall beg leave to continue the ſeparation of the Apple from the Pear, as hath been always practiſed by the botaniſts before his time.

The SPECIES are,

1. MALUS (*Sylveſtris*) foliis ovatis ſerratis, caule arboreo. *Apple with oval ſawed leaves, and a tree-like ſtalk.* Malus ſylveſtris, fructu valde acerbo. Tourn. Inſt. R. H. 635. *Wild Apple with a very ſour fruit, commonly called Crab.*
2. MALUS (*Coronaria*) foliis ſerrato-anguloſis. *Apple with angular ſawed leaves.* Malus ſylveſtris Virginiana, floribus odoratis, Cat. Hort. *Wild Crab of Virginia, with a ſweet-ſcented flower.*
3. MALUS (*Pumila*) foliis ovatis ſerratis, caule fruticoſo. *Apple with oval ſawed leaves and a ſhrubby ſtalk.* Malus

pumila quæ potiùs frutex quam arbor. C. B. P. 433. *Dwarf Apple, which is rather a ſhrub than a tree, commonly called Paradiſe Apple.*

Of the firſt ſort there are two varieties of fruit, one is white, and the other purple toward the ſun, but theſe are accidental variations. There is alſo a variety of this with variegated leaves, which has been propagated in ſome of the nurſeries near London; but when the trees grow vigorous, their leaves ſoon become plain.

The ſecond ſort grows naturally in moſt parts of North America, where the inhabitants plant them for ſtocks to graft other ſorts of Apples upon; the leaves of this are longer and narrower than any of the other ſorts, and are cut into two acute angles on their ſides. The flowers of this have a fragrant odour, which perfumes the American woods at the time they appear.

The third ſort is undoubtedly a diſtinct ſpecies from all the others, for it never riſes to any height; the branches are weak, ſcarce able to ſupport themſelves, and this difference is permanent when raiſed from ſeeds.

I have not diſtinguiſhed the Apples from the Crab, as diſtinct ſpecies, though I have never ſeen any Apples produced from the ſeeds of Crabs. I ſhall next mention a few of thoſe ſorts of Apples which have been introduced from France, which were moſt of them grafted on Paradiſe ſtocks, ſo were for ſome time much eſteemed, and ſhall mention thoſe of our own growth afterward.

There is alſo a ſort of Apple, called the Fig Apple, which is common to England and North America, but the fruit is not greatly eſteemed; however, as ſome perſons are fond of variety, ſo I have mentioned it.

Pomme de Rambour. The Rambour is a very large fruit, of a fine red next the ſun, and ſtriped with a pale or yellowiſh green. This ripens very early, commonly about the end of Auguſt, and ſoon grows mealy, therefore is not eſteemed in England.

Pomme de Courpendu, the hanging body. This is a very large Apple, of an oblong figure, having ſome irregular riſing or angles, which run from the baſe to the crown; it is of a red caſt on the ſide toward the ſun, but pale on the other ſide; the foot-ſtalk is long and ſlender, ſo that the fruit is always hanging downward, which occaſioned the French gardeners to give it this name.

The Rennette-blanche, or White Renette, or French Rennette. This is a large fine fruit, of a roundiſh figure, and of a pale green, changing a little yellowiſh when ripe, having ſome ſmall gray ſpots; the juice is ſugary, and it is good for eating or baking; it will keep till after Chriſtmas ſound.

The Rennette-griſe. This is a middle ſized fruit, ſhaped like the Golden Rennette, but is of a deep gray colour on the ſide next the ſun, but on the other ſide intermixed with yellow; it is a very juicy good Apple, of a quick flavour. It ripens in October, and will not keep long.

Pomme d'Api. This is a ſmall hard fruit, of a bright purple colour on the ſide next the ſun, and of a yellowiſh green on the other ſide; it is a very firm fruit, but hath not much flavour, ſo is only preſerved by ſome perſons by way of curioſity. It keeps a long time ſound, and makes a variety in a diſh of fruit.

Le Calville d'Automne, the Autumn Calville. This is a large fruit of an oblong figure, of a fine red colour toward the ſun. The juice is vinous, and much eſteemed by the French.

Fenouillat ou Pomme d'Anis, the Fennel, or Aniſe Apple. This is a middle ſized fruit, a little longer than a Golden Pippin, of a grayiſh colour. The pulp is tender, and has a ſpicy taſte like Aniſe-ſeed; the wood and the leaves are whitiſh.

Pomme Violette, the Violet Apple. This is a pretty large fruit, of a pale green, ſtriped with deep red to the ſun. The juice is ſugary, and has a flavour of Violets, which occaſioned the name.

The Crab, which is the firſt ſort here mentioned, has been generally eſteemed as the beſt ſtock for grafting Apples upon, being very hardy, and of long duration; but of late years there have been few perſons who have been curious enough to raiſe theſe ſtocks, having commonly ſown the kernels of all ſorts of cyder Apples for ſtocks without diſtinction, as theſe are much eaſier to procure than the other; ſo the gardeners generally call all thoſe Crabs, which are produced from the kernels of any ſort of Apple which has not been grafted; but were the kernels of the Crabs ſown, I ſhould prefer thoſe for ſtocks, becauſe they are never ſo luxuriant in their growth as thoſe from Apple kernels, and they will continue longer ſound; beſide, theſe will preſerve ſome of the beſt ſort of Apples in their true ſize, colour, and flavour; whereas the other free ſtocks produce larger fruit, which are not ſo well taſted, nor will they keep ſo long.

The Paradiſe Apple for ſome years paſt was greatly eſteemed for ſtocks, to graft or bud the other ſorts upon; but theſe are not of long duration, nor will the trees grafted upon them ever grow to any ſize, unleſs they are planted ſo low as that the cion may ſtrike root into the ground, when it will be equal to no ſtock; for as the graft will draw its nouriſhment from the ground, ſo the ſtocks will become uſeleſs after; therefore it is only by way of curioſity, or for very ſmall gardens, that theſe ſtocks are proper, ſince there can never be expected any conſiderable quantity of fruit from ſuch trees.

Theſe trees have been much more eſteemed in France, where they were frequently brought to the table in the pots, growing with their fruit upon them; but this being only a curioſity, it never obtained much in England, ſo that the gardeners do not propagate many of them here at preſent.

There is another Apple, which is called the Dutch Paradiſe Apple, much cultivated in the nurſeries for grafting Apples upon, in order to have them dwarfs; and theſe will not decay or canker as the other, nor do they ſtint the grafts near ſo much, ſo are generally preferred for planting eſpaliers or dwarfs, being eaſily kept within the compaſs uſually allotted to theſe trees.

Some perſons have alſo made uſe of the Codlin ſtocks to graft Apples upon, in order to make them dwarf; but the fruit which are produced on ſuch trees are not ſo firm, nor do they laſt near ſo long as thoſe upon Crab ſtocks; therefore the winter fruits ſhould never be grafted upon them.

The Virginian Crab-tree with ſweet flowers, is often preſerved by ſuch perſons as are curious in collecting great variety of trees; it may be propagated by budding or grafting it upon the common Crab or Apple-tree, but it is ſomewhat tender while young; wherefore it ſhould be planted in a warm ſituation, otherwiſe it will be ſubject to ſuffer by an extreme hard winter. The flowers of this tree are ſaid to be exceeding ſweet in Virginia, where it grows in the woods in great plenty; but I could not obſerve much ſcent in ſome of them which have flowered in England, ſo that I am in doubt whether the ſort at preſent in the gardens is the very ſame with that of Virginia; or perhaps it may have degenerated by ſowing the ſeeds, which is the way it was firſt obtained in England.

The Fig Apple is ſuppoſed by many perſons to be produced without a previous flower. But this opinion is rejected by more curious obſervers, who affirm, there is a ſmall flower precedes the fruit, which is very fugacious, ſeldom continuing above a day or two. Now, which of theſe opinions is the right, I have not, as yet, had an opportunity to determine, not having a tree in my own poſſeſſion which is arrived at maturity to produce fruit; though it might reaſonably be expected, that ſuch who have had trees of this kind ſeveral years, might have determined this point long before this time.

I remember an account of a tree of this kind, mentioned in a letter from New England, written by Paul Dudley, Eſq; to the Royal Society, and publiſhed in the Philoſophical Tranſactions, N° 385. which was exceeding large, and produced great quantities of fruit, without any previous flowers; but it grew at ſome diſtance from his habitation, and he having no other opportunity to obſerve it ſtrictly himſelf, but by viſiting the place two or three times about the ſeaſon of flowering, and not being apprized of the ſudden decay of the flowers, they might eaſily be ſuppoſed to have appeared and dropped off, between the times of his viſiting the place.

The other ſorts which are above-mentioned, are what have been introduced from France, but there are not above two or three of them, which are much eſteemed in England, viz. the French Rennette, the Rennette-griſe, and the Violet Apple; the other being early fruit, which do not keep long, and their fleſh is generally meally, ſo they do not deſerve to be propagated, as we have many better fruits in England: but as there may be ſome perſons who are willing to have all the ſorts, I have mentioned them here for their inſtruction; but I ſhall next put down thoſe ſorts of Apples which are beſt eſteemed in England, placing them in the order according to their time of ripening.

The firſt Apple which is brought to the markets, is the Codlin. This fruit is ſo well known in England, that it is needleſs to deſcribe it.

The next is the Margaret Apple: this fruit is not ſo long as the Codlin, of a middling ſize; the ſide next the ſun changes to a faint red, when ripe; the other ſide is of a pale green; the fruit is firm, of a quick pleaſant taſte, but doth not keep long.

The Summer Pearmain is an oblong fruit, ſtriped with red next the ſun; the fleſh is ſoft, and in a ſhort time is meally, ſo that it is not greatly eſteemed.

The Kentiſh Fill Baſket is a ſpecies of Codlin, of a large ſize, and ſomewhat longer ſhaped than the Codlin; this ripens a little later in the ſeaſon, and is generally uſed for baking, &c.

The Tranſparent Apple: this was brought to England a few years ſince, and was eſteemed a curioſity; it came from Peterſburgh, where it is affirmed to be ſo tranſparent, as that the kernels may be perfectly ſeen, when the Apple is held to the light; but, in this country, it is a meally inſipid fruit, ſo not worth propagating.

Loan's Pearmain: this is a beautiful fruit, being of a middling ſize; the ſide next the ſun is of a beautiful red, and ſtriped with the ſame colour on the other; the fleſh is vinous, but as it ſoon grows meally, it is not greatly eſteemed.

The Quince Apple: this is a ſmall fruit, ſeldom larger than the Golden Pippin, but is in ſhape like the Quince, eſpecially toward the ſtalk; the ſide next the ſun is of a ruſſet colour, on the other ſide inclining to yellow: this is an excellent Apple for about three weeks in September, but will not keep much longer.

The Golden Renette is a fruit ſo well known in England, as to need no deſcription; this ripens about Michaelmas, and for about a month is a very good fruit, either for eating raw or baking.

The Aromatic Pippin is alſo a very good Apple: it is about the ſize of a Nonpareil, but not ſo flat, it is a little longer; the ſide next the ſun is of a bright ruſſet colour; the fleſh is breaking, and hath an aromatic flavour. It ripens in October.

The Hertfordſhire Pearmain, by ſome called the Winter Pearmain: this is a good ſized fruit, rather long than round, of a fine red next the ſun, and ſtriped with the ſame colour on the other ſide; the fleſh is juicy, and ſtews well, but is not eſteemed for eating by any nice palates. This is fit for uſe in November and December.

The Kentiſh Pippin is a large handſome fruit, of an oblong figure; the ſkin is of a pale green colour; the fleſh is breaking, and full of juice, which is of a quick acid flavour. This is a very good kitchen fruit, and will keep till February.

The Holland Pippin is larger than the former; the fruit is ſomewhat longer, the ſkin of a darker green, and the fleſh firm and juicy. This is a very good kitchen fruit, and will keep late in the ſeaſon.

The Monſtrous Renette is a very large Apple, of an oblong ſhape, turning red toward the ſun, but of a dark green on the other ſide; the fleſh is apt to be meally, ſo it is not much valued by thoſe who are curious, and only preſerved for the magnitude of the fruit.

The Embroidered Apple is a pretty large fruit, ſomewhat ſhaped like the Pearmain, but the ſtripes of red are very broad, from whence the gardeners have given it this title: it is a middling fruit, and is commonly uſed as a kitchen Apple, though there are many better.

The Royal Ruſſet, by ſome called the Leather Coat Ruſſet, on account of the deep ruſſet colour of the ſkin; this is a large fair fruit, of an oblong figure, broad toward the baſe; the fleſh is inclinable to yellow. This is one of the beſt kitchen Apples we have, and is a very great bearer: the trees grow large and handſome, and the fruit is in uſe from October till April, and is alſo a pleaſant fruit to eat.

Wheeler's Ruſſet is an Apple of a middling ſize, flat, and round; the ſtalk is ſlender, the ſide next the ſun of a light ruſſet colour, and the other ſide inclining to a pale yellow, when ripe; the fleſh is firm, and the juice has a very quick acid flavour, but is an excellent kitchen fruit, and will keep a long time.

Pile's Ruſſet is not quite ſo large as the former, but is of an oval figure, of a ruſſet colour to the ſun, and of a dark green on the other ſide; it is a very firm fruit, of a ſharp acid flavour, but is much eſteemed for baking, and will keep ſound till April, or later, if they are well preſerved.

The Nonpareil is a fruit pretty generally known in England, though there is another Apple which is frequently ſold in the markets for it, which is what the French call Haute-bonne; this is a larger fairer fruit than the Nonpariel, more inclining to the yellow; the ruſſet colour brighter, and it is earlier ripe, and ſooner gone; this is not ſo flat as the true Nonpareil, nor is the juice ſo ſharp, though it is a good Apple in its ſeaſon; but the Nonpareil is ſeldom ripe before Chriſtmas, and where they are well preſerved they will keep till May perfectly ſound; this is juſtly eſteemed one of the beſt Apples that have been yet known.

The Golden Pippin is a fruit almoſt peculiar to England; there are few countries abroad where this ſucceeds well, nor do they produce ſo good fruit in many parts of England as were to be wiſhed; which, in ſome meaſure, is owing to their being grafted on free ſtocks, which enlarges the fruit, but renders it leſs valuable, becauſe the fleſh is not ſo firm, nor the flavour ſo quick, ſo is apt to be dry and meally; therefore this ſhould always be grafted upon the Crab ſtock, which will not canker like the others, and though the fruit will not be ſo fair to the ſight, yet it will be better flavoured and keep longer.

There are yet a great variety of Apples, which, being inferior to thoſe here mentioned, I have omitted, as thoſe which are here enumerated will be ſufficient to furniſh the table and the kitchen, during the whole ſeaſon of theſe fruits; ſo that where theſe ſorts can be had, no perſon of taſte will eat the other.

I ſhall here mention ſome of the Apples which are chiefly preferred for the making of cyder, tho' there are in every cyder country, new ſorts frequently obtained from the kernels; but thoſe hereafter mentioned, have, for ſome years, been in the greateſt eſteem.

All the ſorts of Apples are propagated by grafting or budding upon the ſtocks of the ſame kind, for they will not take upon any other ſort of fruit tree. In the nurſeries there are three ſort of ſtocks generally uſed to graft Apples upon; the firſt are called free ſtocks; theſe are raiſed from the kernels of all ſorts of Apples indifferently, and ſometimes they are alſo termed Crab ſtocks; for all thoſe trees which are produced from the ſeeds before they are grafted, are termed Crabs without any diſtinction; but, as I have before obſerved, I ſhould always prefer ſuch ſtocks as are raiſed from the kernels of Crabs, where they are preſſed for verjuice; and I find ſeveral of the old writers on this ſubject of the ſame mind. Mr. Auſten, who wrote above a hundred years ago, ſays, "The "ſtock which he accounts beſt for Apple grafts is "the Crab, which is better than ſweeter Apple-trees "to graft on, becauſe they are uſually free from "canker, and will become very large trees; and, I "conceive, will laſt longer than ſtocks of ſweeter "Apples, and will make fruits more ſtrong and hardy "to endure froſt;" and it is very certain, that by frequently grafting ſome ſorts of Apples upon free ſtocks, the fruits have been rendered leſs firm and poignant, and of ſhorter duration.

The ſecond ſort of ſtock is the Dutch Creeper, before-mentioned; theſe are deſigned to ſtint the growth of the trees, and keep them within compaſs for dwarfs or eſpaliers.

The third ſort is the Paradiſe Apple, which is a very low ſhrub, ſo only proper for trees which are kept in pots, by way of curioſity, for theſe do not continue long.

Some perſons have made uſe of Codlin ſtocks for grafting of Apples, in order to ſtint their growth; but as theſe are commonly propagated by ſuckers, I would by no means adviſe the uſing of them; nor would I chuſe to raiſe the Codlin-trees from ſuckers, but rather graft them upon Crab ſtocks, which will cauſe the fruit to be firmer, laſt longer, and have a ſharper flavour; and theſe trees will laſt much longer ſound, and never put out ſuckers, as the Codlins always do, which, if not conſtantly taken off, will weaken the trees, and cauſe them to canker: and it is not only from the roots, but from the knots of their ſtems, there are generally a great number of ſtrong ſhoots produced, which fill the trees with uſeleſs ſhoots, and render them unſightly, and the fruit ſmall and crumpled.

The method of raiſing ſtocks from the kernels of Crabs, or Apples, is, to procure them where they are preſſed for verjuice or cyder, and after they are cleared of the pulp, they may be ſown upon a bed of light earth, covering them over about half an inch thick with the ſame light earth; theſe may be ſown in November or December, where the ground is dry, but in wet ground, it will be better to defer it till February; but then the ſeeds ſhould be preſerved in dry ſand, and kept out of the reach of vermin, for if mice or rats can get at them, they will devour the ſeeds; there ſhould alſo be care taken of the ſeeds, when they are ſown, to protect them from theſe vermin, by ſetting traps to take them, &c. In the ſpring, when the plants begin to appear, they muſt be carefully weeded, and if the ſeaſon ſhould prove dry, it will be of great ſervice to water them two or three times a week; and, during the ſummer, they muſt be kept clean from weeds, which, if ſuffered to grow, will ſoon over-top the plants, and ſpoil their growth; if theſe thrive well, they will be fit to tranſplant into the nurſery the October following, at which time the ground ſhould be carefully digged, and cleanſed from the roots of all bad weeds; then the ſtocks ſhould be planted in rows three feet aſunder, and the plants one foot diſtance in the rows, cloſing the earth pretty faſt to their roots; when the ſtocks are tranſplanted out of the ſeed-bed, the firſt autumn after ſowing, they need not be headed, but where they are inclined to ſhoot downward, the tap root muſt be ſhortened, in order to force out horizontal roots; if the ground is pretty good in which theſe ſtocks are planted, and the weeds conſtantly cleared away, the ſtocks will make great progreſs, ſo that thoſe which are intended for dwarfs, may be grafted the ſpring twelve months after they are planted out of the ſeed-bed; but thoſe which are deſigned for ſtandards will require two or three years more growth, before they will be fit to graft, by which time they will be upward of ſix feet high. The other neceſſary work to be obſerved in the culture of theſe trees, while they remain in the nurſery, being exhibited under the article of NURSERY, I ſhall not repeat in this place.

I ſhall next treat of the manner of planting ſuch of theſe trees, as are deſigned for eſpaliers in the kitchen-garden, where, if there is an extent of ground, it will be proper to plant, not only ſuch ſorts as are for the uſe of the table, but alſo a quantity of trees to ſupply the kitchen; but where the kitchen-garden is ſmall, the latter muſt be ſupplied from ſtandard-trees, either from the orchard, or wherever they are planted; but as many of theſe kitchen Apples are large, and hang late in the autumn upon the trees, they will be much more expoſed to the ſtrong winds on ſtandard trees than in eſpaliers, whereby many of the fruit will be blown down before they are ripe, and others bruiſed, ſo as to prevent their keeping; therefore where it can be done, I ſhould always prefer the planting them in eſpaliers.

The diſtance which I ſhould chuſe to allow theſe trees, ſhould not be leſs than thirty feet, for ſuch ſorts as are of moderate growth (if upon Crab or free ſtocks:) but the larger growing ſorts ſhould not be allowed leſs room than thirty-five or forty feet, which will be found full near enough, if the ground is good, and the trees properly trained; for as the branches of theſe trees ſhould not be ſhortened, but trained at their full length, ſo in a few years they will be found to meet. Indeed, at the firſt planting, the diſtance will appear ſo great to thoſe perſons who have not obſerved the vigorous growth of theſe trees, that they will ſuppoſe they never can extend their branches ſo far, as to cover the eſpalier; but if theſe perſons will but obſerve the growth of ſtandard-trees of the ſame kinds, and ſee how wide their branches are extended on every ſide, they may be ſoon convinced, that as theſe eſpalier-trees are allowed to ſpread but on two ſides, they will of courſe make more progreſs, as the whole nouriſhment of the root will be employed in theſe ſide branches, than where there is a greater number of branches on every ſide of the tree, which are to be ſupplied with the ſame nouriſhment.

The next thing to be obſerved is the making choice of ſuch ſorts of fruits as grow nearly alike, to plant in the ſame eſpalier. This is of great conſequence, becauſe of the diſtance they are to be placed, otherwiſe thoſe ſorts which make the largeſt ſhoots, may be allowed leſs room to ſpread than thoſe of ſmaller growth; beſide, when all the trees in one eſpalier are nearly equal in growth, they will have a better appearance than when ſome are tall, and others ſhort; but for the better inſtruction of thoſe perſons who are not converſant in theſe things, I ſhall divide the ſorts of Apples into three claſſes according to their different growths.

Largeſt growing tree.	Middle growing tree.	Smalleſt growing tree.
All the ſorts of Pearmains.	Margaret Apple.	Quince Apple.
Kentiſh Pippin.	Golden Renette.	Tranſparent Apple.
Holland Pippin.	Aromatic Pippin.	Golden Pippin.
Monſtrous Renette.	Embroidered Apple.	Pomme d'Api.
Royal Ruſſet.	Renette Griſe.	Fenouillet, or Anis Apple.
Wheeler's Ruſſet.	White Renette.	
Pile's Ruſſet.	Codlin.	
Nonpareil.		
Violet Apple.		

N. B. Theſe are all ſuppoſed to be grafted on the ſame ſort of ſtocks.

If theſe Apples are grafted upon Crab ſtocks, I would willingly place them at the following diſtance from each other, eſpecially where the ſoil is good, viz. the largeſt growing trees at forty feet, the middle growing at thirty feet, and the ſmall growing at twenty-five feet, which, from conſtant experience, I find to be full near enough; for in many places, where I have planted theſe trees at twenty-four feet diſtance, they have ſhot ſo ſtrong, as that in ſeven years their branches have met; and in ſome places where every other tree hath been taken up, the branches have almoſt joined in ſeven years after; therefore it will be much the better way to plant theſe trees at a proper diſtance at firſt, and between theſe to plant ſome Dwarf Cherries, Currants, or other ſorts of fruit, to bear for a few years, which may be cut away when the Apple-trees have extended their branches to them; for when the Apple-trees are planted nearer together, few perſons care to cut down the trees, when they are fruitful, ſo that they are obliged to uſe the knife, ſaw, and chiſel, more than is proper for the future good of the trees; and many times, where perſons are inclinable to take away part of their trees, the diſtances will be often ſo irregular (where there was not this conſideration in their firſt planting,) as to render the eſpalier unſightly.

When the trees are upon the Dutch Dwarf ſtock, the diſtance ſhould be for the larger growing trees thirty feet, for thoſe of middle growth twenty-five, and the ſmalleſt twenty feet, which will be found full near where the trees thrive well.

The next is the choice of the trees, which ſhould not be more than two years growth from the graft, but thoſe of one year ſhould be preferred; you ſhould alſo be careful, that their ſtocks are young, ſound, and ſmooth, free from canker, and which have not been cut down once or twice in the nurſery; when they are taken up, all the ſmall fibres ſhould be entirely cut off from their roots, which, if left on, will turn mouldy and decay, ſo will obſtruct the new fibres, which will ſoon puſh out, in their growth; the extreme part of the roots muſt alſo be ſhortened, and all bruiſed roots cut off; and if there are any miſplaced roots which croſs each other, they ſhould alſo be cut away. As to the pruning of the head of theſe trees, there need be nothing more done than to cut off any branches which are ſo ſituated, as that they cannot be trained to the line of the eſpalier: in the planting, there muſt be care taken not to place their roots too deep in the ground, eſpecially if the ſoil is moiſt, but rather raiſe them on a little hill, which will be neceſſary to allow for the raiſing of the borders afterward. The beſt ſeaſon for planting theſe trees (in all ſoils which are not very moiſt) is, from October, to the middle or latter end of November, according as the ſeaſon continues mild; but ſo ſoon as the leaves fall, they may be removed with great ſafety. After the trees are planted, it will be proper to place down a ſtake to each tree, to which the branches ſhould be faſtened, to prevent the winds from ſhaking or looſening their roots, which will deſtroy the young fibres; for when theſe trees are planted pretty early in autumn, they will very ſoon puſh out a great number of new fibres, which, being very tender, are ſoon broken, by the wind ſhaking of the trees, whereby they are greatly injured. If the winter ſhould prove ſevere, it will be proper to lay ſome rotten dung, tanners bark, or ſome other ſort of mulch about their roots, to prevent the froſt from penetrating of the ground, which might damage theſe tender fibres; but I would not adviſe the laying of this mulch before the froſt begins, for if it is laid over the ſurface of the ground about their roots, ſoon after the trees are planted (as is often practiſed,) it will prevent the moiſture entering the ground, and do much more harm than good to the trees.

The following ſpring, before the trees begin to puſh, there ſhould be two or three ſhort ſtakes put down on each ſide every tree, to which the branches ſhould be faſtened down as horizontally as poſſible, never cutting them down, as is by ſome practiſed, for there will be no danger of their putting out branches enough to furniſh the eſpalier, if the trees are once well eſtabliſhed in their new quarters.

In the pruning of theſe trees, the chief point is, never to ſhorten any of the branches, unleſs there is an abſolute want of ſhoots to fill the ſpaces of the eſpalier; for where the knife is much uſed, it only multiplies uſeleſs ſhoots, and prevents their fruiting; ſo that the beſt method to manage theſe trees is, to go over them three or four times in the growing ſeaſon, and rub off all ſuch ſhoots as are irregularly produced, and train the others down to the ſtakes in the poſition they are to remain: if this is carefully performed in ſummer, there will be little left to be done in the winter, and by bending of their ſhoots from time to time, as they are produced, there will be no occaſion to uſe force to bring them down, nor any danger of breaking the branches. The diſtance which theſe branches ſhould be trained from each other, for the largeſt ſorts of fruits ſhould be about ſeven or eight inches, and for the ſmaller four or five. If theſe plain inſtructions are followed, it will ſave much unneceſſary labour of pruning, and the trees will, at all times, make a handſome appearance; whereas when they are ſuffered to grow rude in ſummer, there will be much greater difficulty to bring down their ſhoots, eſpecially if they are grown ſtubborn, when it may become neceſſary to ſlit the branches to make them pliable. All the ſorts of Apples produce their fruit upon curſons, or ſpurs, ſo that theſe ſhould never be cut off, for they will continue fruitful a great number of years.

The method of making the eſpaliers having been already exhibited under that article, I need not repeat it here, but only obſerve, that it will be beſt to defer making the eſpalier till the trees have had three or four years growth; for before that time, the branches may be ſupported by a few upright ſtakes, ſo that there will be no neceſſity to make the eſpalier, until there are ſufficient branches to furniſh all the lower part.

I ſhall now treat of the method to plant orchards, ſo as to have them produce the greateſt profit. And firſt, in the choice of the ſoil and ſituation for an orchard: the beſt ſituation for an orchard is, on the aſcent of the gentle hills, facing the ſouth, or ſouth-eaſt; but this aſcent muſt not be too ſteep, leſt the earth ſhould be waſhed down by haſty rains. There are many perſons who prefer low ſituations at the foot of hills, but I am thoroughly convinced from experience, that all bottoms where there are hills on each ſide, are very improper for this purpoſe; for the air is drawn down into theſe vallies in ſtrong currents, which, being pent in renders theſe bottoms much colder than the open ſituations; and during the winter and ſpring, theſe bottoms are very damp and unhealthy to all vegetables; therefore the gentle riſe of a hill, fully expoſed to the ſun and air, is by much the beſt ſituation. As to the ſoil, a gentle hazel loam, which is eaſy to work, and that doth not detain the wet, is the beſt; if this happens to be three feet deep, it will be better for the growth of the trees, for although theſe trees will grow upon very ſtrong land, yet they are ſeldom ſo thriving, nor are their fruit ſo well flavoured, as thoſe which grow on a gentle ſoil; and on the other hand, theſe trees will not do well upon a very dry gravel or ſand, therefore thoſe ſoils ſhould never be made choice of for orchards.

The ground intended to be planted ſhould be well prepared the year before, by ploughing it thoroughly, and if ſome dung is laid upon it the year before, it will be of great ſervice to the trees; if in the preceding ſpring a crop of Peas or Beans is planted on the ground (provided they are ſown or planted in rows, at a proper diſtance, ſo as that the ground between them is horſe-hoed,) it will deſtroy the weeds, and looſen the ground, ſo that it will be a good preparation for the trees, for the earth cannot be too much wrought, or pulveriſed for this purpoſe: theſe crops will be taken off the ground long before the ſeaſon for planting of theſe trees, which ſhould be as ſoon as poſſible performed when the trees begin to ſhed their leaves.

In chuſing of the trees, I would adviſe the taking ſuch as are but of two years growth from the graft, and never to plant old trees, or ſuch as are grafted upon old ſtocks, for it is loſing of time to plant theſe; young trees being always more certain to grow, and make a much greater progreſs than thoſe which are old. As to pruning of the roots, it muſt be done in the ſame manner as hath been already directed for the eſpalier-trees; and in pruning their heads, little more is neceſſary than to cut out ſuch branches as are ill placed, or that croſs each other; for I do not approve the heading of them down, as is by ſome often practiſed to the loſs of many of their trees.

The diſtance which theſe trees ſhould be planted, where the ſoil is good, muſt be fifty or ſixty feet; and where the ſoil is not ſo good, forty feet may be ſufficient; but nothing can be of worſe conſequence, than the crowding trees too cloſe together in orchards. And although there may be ſome who may imagine this diſtance too great, yet I am ſure, when they have thoroughly conſidered the advantages attending this practice, they will agree with me. Nor is it my own opinion in this affair, for in many of the old writers on this ſubject, there is often mention made of the neceſſity for allowing a proper diſtance to the fruit-trees in orchards, particularly Auſten, upon planting before quoted, who ſays, "He ſhould chuſe to preſcribe the planting theſe trees fourteen or ſixteen yards aſunder; for both trees and fruits have many great advantages, if planted a good diſtance one from another." One advantage he mentions is, "The ſun refreſhes every tree, the roots, body, and branches, with the bloſſoms and fruits; whereby trees bring forth more fruit, and thoſe fairer and better." Another advantage he mentions is, "That when trees are planted at a large diſtance, much profit may be made of the ground under and about theſe trees, by cultivating garden-ſtuff, commodious as well for ſale as houſekeeping; as alſo Gooſeberries, Raſpberries, Currants, and Strawberries, may be there planted." Again he ſays, "When trees have room to ſpread, they will grow very large and great; and the conſequences of that will be, not only multitudes of fruits, but alſo long laſting, and theſe two are no ſmall advantages." For, ſays he, "Men are miſtaken, when they ſay, the more trees in an orchard, the more fruits; for one or two large trees which have room to ſpread, will bear more fruits than ſix or ten (it may be) of thoſe that grow near together, and crowd one another." Again he ſays, "Let men but obſerve, and take notice of ſome Apple-trees, that grow a great diſtance from other trees, and have room enough to ſpread both their roots and branches, and they ſhall ſee, that one of thoſe trees (being come to full growth) hath a larger head, and more boughs and branches, than (it may be) four, or ſix, or more, of thoſe which grow near together, although of the ſame age."

And Mr. Lawſon, an ancient planter, adviſes to plant Apple-trees twenty yards aſunder. As the two authors above quoted have written the beſt upon this ſubject, and ſeem to have had more experience than any of the writers I have yet ſeen, I have made uſe of them as authorities to confirm what I have advanced; though the fact is ſo obvious to every perſon who will make the leaſt reflection, that there needs no other proof.

When the trees are planted, they ſhould be ſtaked, to prevent their being ſhaken, or blown out of the ground by ſtrong winds; but in doing of this, there ſhould be particular care taken, to put either ſtraw, haybands, or woollen cloth, between the trees and the ſtakes, to prevent the trees from being rubbed and bruiſed, by the ſhaking againſt the ſtakes, for if their bark ſhould be rubbed off, it will occaſion ſuch great wounds, as not to be healed over in ſeveral years, if they ever recover it.

If the winter ſhould prove very ſevere, it will be proper to cover the ſurface of the ground about their roots with ſome mulch, to prevent the froſt from penetrating the ground, which will deſtroy the young fibres; but this mulch ſhould not be laid on too ſoon, as hath been before mentioned, leſt the moiſture ſhould be prevented from ſoaking down to the roots of the trees, nor ſhould it lie on too long in the ſpring for the ſame reaſon; therefore where perſons will be at the trouble to lay it on in froſty weather, and remove it again after the froſt is over, that the wet in February may have free acceſs to the roots of the trees; and if March ſhould prove dry, with ſharp north or eaſt winds, which often happens, it will be proper to cover the ground again with the mulch, to prevent the winds from penetrating and drying the ground, and will be of ſingular ſervice to the trees. But I am aware, that this will be objected to by many, on account of the trouble, which may appear to be great; but when it is conſidered, how much of this buſineſs may be done by a ſingle perſon in a ſhort time, it can have little force, and the benefit which the trees will receive by this management, will greatly recompenſe the trouble and expence.

As theſe trees muſt be conſtantly fenced from cattle, it will be the beſt way to keep the land in tillage for ſome years, that by conſtant ploughing or digging of the ground, the roots of the trees will be more encouraged, and they will make the more progreſs in their growth; but where this is done, whatever crops are ſown or planted, ſhould not be too near the trees, leſt the nouriſhment ſhould be drawn away from the trees; and as in the ploughing of the ground where it is ſo tilled, there muſt be care taken not to go too near the ſtem of the trees, whereby their roots would be injured, or the bark of their ſtems rubbed off, ſo it will be of great ſervice to dig the ground about the trees where the plough doth not come, every autumn, for five or ſix years after planting, by which time their roots will have extended themſelves to a greater diſtance.

It is a common practice in many parts of England, to lay the ground down for paſture, after the trees are grown pretty large in their orchards; but this is by no means adviſeable, for I have frequently ſeen trees of above twenty years growth, almoſt deſtroyed by horſes, in the compaſs of one week; and if ſheep are put into orchards, they will conſtantly rub their bodies againſt the ſtems of the trees, and their greaſe ſticking to the bark, will ſtint their growth, and in time will ſpoil them; therefore wherever orchards are planted, it will be much the better method to keep the ground ploughed or dug annually, and ſuch crops put on the ground as will not draw too much nouriſhment from the trees.

In pruning of orchard-trees, nothing more ſhould be done, but to cut out all thoſe branches which croſs each other, and, if left, would rub and tear off the bark, as alſo decayed branches, but never ſhorten any of their ſhoots. If ſuckers, or ſhoots from their ſtems, ſhould come out, they muſt be entirely taken off annually; and when any branches are broken by the wind, they ſhould be cut off, either down to the diviſion of the branch, or cloſe to the ſtem from whence it was produced; the beſt time for this work is in November, for it ſhould not be done in froſty weather, nor in the ſpring, when the ſap begins to be in motion.

The beſt method to keep Apples for winter uſe is, to let them hang upon the trees until there is danger of froſt, and to gather them in dry weather, laying them in large heaps to ſweat for three weeks or a month; afterward look them over carefully, taking out all ſuch as have appearance of decay, wiping all the ſound fruit dry, and pack them up in large oil-jars, which have been thoroughly ſcalded and dry, ſtopping them down cloſe to exclude the external air: if this is duly obſerved, the fruit will keep ſound a long time, and their fleſh will be plump; for when they are expoſed to the air, their ſkins will ſhrink, and their pulp will be ſoft.

MAMMEA. Plum. Nov. Gen. 44. tab. 4. Lin. Gen. Plant. 583. The Mammee-tree.

The CHARACTERS are,

The empalement of the flower is compoſed of two ſmall, oval, concave leaves, which fall off. The flower has four large concave petals, which ſpread open. It hath many awl-ſhaped ſtamina, terminated by roundiſh ſummits, and in the center a roundiſh germen, with a conical ſtyle the length of the ſtamina, crowned by a ſingle permanent ſtigma. The germen afterward turns to a large fleſhy fruit, of a ſpherical figure, incloſing one, two, or three large almoſt oval ſtones.

This genus of plants is ranged in the firſt ſection of Linnæus's thirteenth claſs, intitled Polyandria Monogynia, which includes the plants whoſe flowers have many ſtamina and one ſtyle.

There is but one SPECIES of this tree known in the Engliſh gardens, viz.

MAMMEA ſtaminibus flore brevioribus. *Mammee with the ſtamina ſhorter than the flower.* Mammea magno fructu, perſicæ ſapore. Plum. Nov. Gen. 44. *Mammee with a large fruit, having the taſte of a Peach.*

This tree, in the Weſt-Indies, grows to the height of ſixty or ſeventy feet; the leaves are large and ſtiff, and continue green all the year; the fruit is as large as a man's fiſt; when ripe, it is of a yellowiſh green colour, and is very grateful to the taſte. It grows in great plenty in the Spaniſh Weſt-Indies, where the fruit is generally ſold in their markets, and is eſteemed one of the beſt fruits in the country. It alſo grows on the hills of Jamaica, and has been tranſplanted into moſt of the Caribbee Iſlands, where it thrives exceeding well.

In England there are ſome few of theſe plants, which are preſerved with great care by ſuch as are curious in cultivating exotic plants; but there are none of any conſiderable ſize, ſo that we cannot expect to ſee either fruit or flowers for ſome years. Theſe plants may be propagated by planting the ſtones, which are often brought from the Weſt-Indies, (which ſhould be very freſh, otherwiſe they will not grow,) into pots filled with freſh light earth, and plunged into a hot-bed of tanners bark, obſerving to water the earth whenever it appears dry. In about a month or ſix weeks the plants will appear above ground, after which they muſt be frequently refreſhed with water, and in hot weather the glaſſes of the hot-bed ſhould be raiſed to let in freſh air. In two months the roots of the plants will have filled the pots, when you ſhould provide ſome pots of a little larger ſize, into which you ſhould tranſplant the plants, being careful to preſerve as much earth to their roots as poſſible; then you ſhould fill up the pots with freſh light earth, and plunge them into the bark-bed again, obſerving to water and ſhade them until they have taken root, after which they ſhould be conſtantly refreſhed with water as you ſhall find they want it, and muſt have air in hot weather. In this bed they may remain till Michaelmas, when they muſt be removed into the bark-ſtove, where they muſt be conſtantly kept, obſerving to refreſh them with water, but it muſt be given to them ſparingly at this ſeaſon, as alſo to clean their leaves from the filth they are apt to contract in the ſtove; the ſpring following they ſhould be ſhifted into freſh earth, and if they require it, into larger pots, but by no means over-pot them, for they do not produce many roots, therefore if the pots are too large the plants will not thrive; they muſt be conſtantly kept in the bark-ſtove, and may be treated after the manner directed for the Coffee-tree.

If, when the ſtones of this fruit are brought over, they are put into the tan-bed, under the bottom of any of the pots, they will ſprout ſooner than thoſe which are planted in the earth.

MANCANILLA. See HIPPOMANE.

MANDRAGORA. Tourn. Inſt. R. H. 76. tab. 12. Lin. Sp. Plant. 221. Mandrake; in French, *Mandragore.*

The CHARACTERS are,

The empalement of the flower is large, bell-ſhaped, erect, and permanet; it is of one leaf, cut at the top into five acute ſegments. The flower hath one erect bell-ſhaped petal which ſpreads open, and is a little larger than the empalement. It has five awl-ſhaped ſtamina, which are arched and hairy at their baſe. In the center is ſituated a roundiſh germen, ſupporting an awl-ſhaped ſtyle, crowned by a headed ſtigma. The germen afterward turns to a large round berry with two cells, having a fleſhy receptacle convex on each ſide, filled with kidney-ſhaped ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, which contains thoſe plants whoſe flowers have five ſtamina and one ſtyle.

We have but one SPECIES of this genus in the Engliſh gardens, viz.

MANDRAGORA (*Officinarum.*) Hort. Cliff. 51. *The Mandrake.* Mandragora fructu rotundo. C. B. P. 169. *Mandrake with a round fruit.*

This plant grows naturally in Spain, Portugal, Italy, and the Levant, but is preſerved here in the gardens of the curious. It hath a long taper root ſhaped like Parſnep, which runs three or four feet deep in the ground; it is ſometimes ſingle, and at others divided into two or three branches, almoſt of the colour of Parſnep, but a little darker; from this ariſes a circle of leaves, which at firſt ſtand erect, but, when grown to their full ſize, ſpread open, and lie upon the ground; they are more than a foot in length, and four or five inches broad in the middle, growing narrow toward both ends, of a dark green colour, and a fœtid ſcent. Theſe riſe immediately from the crown of the root, without any foot-ſtalk; between them come out the flowers, each ſtanding upon a ſeparate foot-ſtalk about three inches long, which alſo ariſe immediately from the root; they are five-cornered, of an herbaceous white colour, ſpreading open at the top like a Primroſe, having five hairy ſtamina, with a globular germen in the center, ſupporting an awl-ſhaped ſtyle. The germen afterward turns to a globular ſoft berry lying upon the leaves, which, when fully grown, is as large as a Nutmeg, of a yellowiſh green colour when ripe, full of pulp, in which the kidney-ſhaped ſeeds are lodged. It flowers in March, and the ſeeds are ripe in July.

This plant is propagated by ſeeds, which ſhould be ſown upon a bed of light earth ſoon after they are ripe, for if they are kept until the ſpring, they ſeldom ſucceed well; but thoſe which are ſown in autumn will come up in the ſpring, when they ſhould be carefully cleared from weeds; and in very dry weather they muſt be refreſhed with water, which will greatly promote their growth. In this bed they ſhould remain till the latter end of Auguſt, (obſerving always to keep them clear from weeds) at which time they ſhould be taken up very carefully, and tranſplanted into the places where they are to remain; the ſoil ſhould be light and deep, for their roots always run very deep, ſo that if the ſoil is wet, they are often rotted in winter; and if it be too near the gravel or chalk, they will make but little progreſs; but if the ſoil be good and they are not diſturbed, the plants will grow to a large ſize in a few years, and will produce great quantities of flowers and fruit; the roots will abide a great many years.

I have been informed by ſome perſons of credit, that one of theſe roots will remain ſound above fifty years, and be as vigorous as a young plant. I have known ſome plants myſelf near that age, which are now in great vigour, and may continue ſo many years longer, as there are no ſigns of their decay; but they ſhould never be removed after their roots have arrived to any conſiderable ſize, which would break their lower fibres, and ſo ſtint the plants, as that if they live they will not recover their former ſtrength in two or three years. Theſe plants ſhould have a warm ſituation, otherwiſe in ſevere winters they will be deſtroyed.

As to the feigned reſemblance of a human form, which the roots of this plant are ſaid to carry, it is all impoſture, owing to the cunning of quacks and mountebanks, who deceive the populace and the ignorant with fictitious images, ſhaped from the freſh roots of Briony and other plants: and what is reported as to the manner of rooting of this plant, by tying a dog thereto, to prevent the certain death of the perſon who ſhould care to attempt it, and the groans it emits upon the force offered, &c. is all a ridiculous fable; for I have taken up ſeveral large roots of this plant, ſome of which have been tranſplanted into other places, but could never obſerve any particular difference in this from any other deep rooting plant.

MANGIFERA. Lin. Gen. Plant. 278. The Mango-tree.

The CHARACTERS are,

The empalement of the flower is cut into five ſpear-ſhaped ſegments; the flower hath five ſpear-ſhaped petals longer than the empalement, and five awl-ſhaped ſtamina the length of the corolla, crowned with heart-ſhaped ſummits. It hath a roundiſh germen, ſupporting a ſlender ſtyle the length of the empalement, terminated by a ſingle ſtigma; the germen afterward becomes an oblong kidney-ſhaped Plumb ſomewhat compreſſed, incloſing an oblong woolly nut of the ſame form.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, the flower having five ſtamina and one ſtyle.

We have but one SPECIES of this genus, viz.

MANGIFERA (*Indica.*) Lin. Sp. 290. *The Mango-tree.* Manga Indica fructu magno reniforma. Raii Hiſt. 1550.

This tree grows naturally in moſt parts of India, as alſo in the Brazils, and ſome other parts of the world, where it becomes a large tree; the wood is brittle, and the bark becomes rough by age; the leaves are ſeven or eight inches long, and two or more broad, terminating in points, having ſeveral tranſverſe veins from the middle rib to the ſides, which are oppoſite. The flowers are produced in looſe panicles toward the end of the branches, each conſiſting of five ſpear-ſhaped petals which ſpread open, having five awl-ſhaped ſtamina the length of the petals, which are ſituated between them; the germen at the bottom of the flower afterward becomes a large oblong kidney-ſhaped Plumb, incloſing a rough nut of the ſame form.

This fruit, when fully ripe, is greatly eſteemed by the inhabitants of thoſe countries where they grow naturally, or have been tranſplanted; but in Europe we have only the unripe fruit brought over in pickle, which is little better than ſeveral other fruit when pickled in the ſame way: however, from the account given of the ripe fruit, by moſt people who have eaten it in the country; it has excited the curioſity of many perſons in Europe to endeavour to procure young plants in their gardens, for which purpoſe great quantities of the nuts have been brought to ſeveral parts of Europe, but without effect; for I have not heard of one plant which has been produced in Europe from the nuts. All thoſe which have fallen into my hands have been rotten when received, ſo that I am apt to think the vegetative quality of them cannot be long preſerved; therefore the only method to obtain the plants in England, is to plant a good quantity of the nuts in a tub of earth in the country where they grow naturally; and when the plants are grown a foot high, to ſhip them for England, placing a covering over them to defend them from ſalt water and the ſpray of the ſea, being very careful not to let them have much wet in their paſſage; as alſo when the ſhip arrives in a cold climate, to ſcreen the plants from cold, eſpecially if it is toward the approach of winter. By carefully obſerving theſe rules, the plants may be brought very ſafely over, as has been experienced by a plant of this ſort, with ſeveral other ſorts of plants, which were brought over by Capt. Quick, and are now in good health in the Chelſea garden.

There have been ſome plants brought to England before this, which were deſtroyed by having too much heat, for this plant will not thrive in a hot-bed of tanners bark; ſo that the only way to have them ſucceed, is to plant them in pots filled with light kitchen-garden earth, and place them in a dry ſtove, where in warm weather they ſhould have freſh air daily, and in the winter the air kept up to temperate, as is marked upon the thermometers.

MANIHOT. See JATROPHA.

MANURE.

There are various kinds of Manure, which are now commonly uſed in different parts of England, for enriching of the ſeveral ſoils. Some of theſe have been already mentioned under the article of DUNG, ſo I ſhall not repeat them here, but proceed to take notice of ſome other kinds of Manure, which are at preſent neglected by many people, though they might be uſed with equal ſucceſs, if not better on many lands, as moſt of thoſe now commonly in uſe.

Oak bark, after the tanners have uſed it for tanning of leather, when laid in a heap and rotted, is an excellent Manure, eſpecially for ſtiff cold land; in which one load of this Manure will improve the ground more, and laſt longer, than two loads of the richeſt dungs; and yet it is very common to ſee large heaps of this remaining in the tanners yards for many years, in ſeveral parts of England, where Manure of other kinds is very ſcarce, and often carried to a great diſtance. Of late years this tan has been much uſed for hot-beds in ſeveral parts of England, and is found greatly to exceed horſe dung for that purpoſe, the fermentation being moderate and of long continuance; ſo that a bed of tan, when rightly made, will continue in a moderate temperature of heat for three or four months; and when the heat begins to decay, if it be ſtirred up with a dung fork, and ſome freſh tan added to it, the heat will renew again, and laſt for ſome months, ſo that theſe beds are by far the moſt kindly for exotic plants; and whatever plants are plunged into theſe beds, if they are permitted to root through the bottom of the pots, they will thrive more in one month after, than they did in four months while they are confined to the pots. I have frequently obſerved many kinds of plants, which were rooted through the pot into the tan, and have ſent forth roots upward of twelve feet each way, in leſs than three months, and the plants have advanced in proportion; which is a plain indication, that plants are greatly nouriſhed by the rotten tan. After the tan hath been uſed for a hot-bed, I have ſpread it on the ground for Manure, and found it has greatly enriched the ground; but it is much better for cold ſtrong land, than for light hot ground, becauſe it is of a warm nature, and will looſen and ſeparate the earth; ſo that where this Manure hath been uſed three or four times, it hath made the land very looſe which before was ſtrong, and not eaſy to be wrought. When this Manure is laid upon Graſs, it ſhould be done ſoon after Michaelmas, that the winter rains may waſh it into the ground; for if it is laid on in the ſpring, it will burn the Graſs, and inſtead of improving it, will greatly injure it for that ſeaſon. Where it is uſed in Corn land, it ſhould be ſpread on the ſurface before the laſt ploughing, that it may be turned down for the fibres of the Corn to reach it in the ſpring; for if it lies too near the ſurface, it will forward the growth of the Corn in winter: but in the ſpring, when the nouriſhment is chiefly wanted to encourage the ſtems, it will be nearly conſumed, and the Corn will receive little advantage from it. Nor will it be proper to have this Manure lie too near the roots of any plants, for when this has happened, I have frequently obſerved it prejudicial to moſt plants, but eſpecially to bulbous and tuberoſe-rooted flowers, which are very ſubject to rot where it lies near their roots; yet when it is buried juſt deep enough for the fibres of their roots to reach it in the ſpring, the flowers have been exceedingly improved by it. And in ſome places, where this Manure hath been uſed in kitchen-gardens, it hath greatly improved the vegetables; ſo that it is to be wondered, that this ſhould not be employed on the land in every country where it can be obtained.

Rotten vegetables of moſt ſorts alſo will enrich land, ſo that where other Manure is ſcarce, theſe may be uſed with ſucceſs. The weeds of ponds, lakes, or ditches, being dragged out before they ſeed, and laid in heaps to rot, will make good Manure, as will moſt other ſorts of weeds; but wherever any of theſe are employed, they ſhould be cut down as ſoon as they begin to flower, for if they are ſuffered to ſtand until their ſeeds are ripe, the land will be ſtored with weeds, which cannot be eaſily deſtroyed; nay, ſome kinds of weeds, if they are permitted to ſtand ſo long as to form their ſeed, will perfect them after they are cut down, which may be equally prejudicial to the land: therefore the ſureſt method is, to cut them down juſt as they begin to flower; at which time moſt ſorts of vegetables are in their greateſt vigour, being then ſtronger and fuller of juice, than when their ſeeds are farther advanced; ſo that at that time they abound moſt with ſalts, and therefore are more proper for the intended purpoſe. In rotting of theſe vegetables, it will be proper to mix ſome earth, mud, or any other ſuch like ſubſtance with them, to prevent their taking fire in their fermentation; which they are very ſubject to, where they are laid in large heaps without any other mixture to prevent it; and it will be alſo proper to cover the heaps over with earth, mud, or dung, to detain the ſalts, otherwiſe many of the finer particles will evaporate in fermenting. When theſe vegetables are thoroughly rotted, they will form a ſolid maſs, which will cut like butter, and be very full of oil, which will greatly improve land.

In ſuch places where there are neither ponds, lakes, or ditches, to ſupply theſe weeds, and the ſituation being far from the ſea (from whence alſo may be obtained many ſorts of weeds for this purpoſe) there may be many ſorts of vegetables ſown, in order to plough them into the grounds when they are full grown, to enrich the land; at preſent thoſe chiefly uſed for this purpoſe are Buck Wheat, Vetches, and Spurry. And in ſome countries abroad they commonly ſow Lupines upon ſuch land as they want to improve, and when they are full grown they mow them down, and plough them into the ground, which they eſteem to be good Manure. This is chiefly uſed in the ſouth of France and in Italy, where ſome of the ſorts of Lupines grow naturally; but theſe are not proper for this climate, becauſe, if the ſeaſon ſhould prove cold or wet after the Lupines are ſown, they will rot in the ground, ſo that it is very hazardous to ſow them in this country; and there being many other ſorts of plants which are hardy, and grow to a much larger ſize with us than Lupines, they ſhould be preferred to them for this purpoſe. I have known ſome land ſown pretty thick with Horſe-beans which have been mowed down when they were in bloſſom, and ploughed in for a crop of Wheat, and it hath largely repaid the owner. Almoſt any of the pulſe kind, which grow large, are very proper to be ſown for this purpoſe; and next to theſe may be ſown Muſtard, Cole-ſeed, or any of theſe large growing plants; which, if cut before they form their ſeeds, and ploughed in, will greatly enrich the ground.

The refuſe of kitchen-gardens, when laid in heaps and rotted, will alſo afford a good ſort of Manure for Corn land; but as this is not to be obtained in any quantity, excepting near great cities, ſo, in ſuch places, dung being to be had pretty reaſonable, the other will not be much ſought after.

I have lately been informed of another improvement, which may be of great uſe in ſeveral parts of the kingdom; which is, the mowing down of Fern while it is green and tender, and laying it in heaps to rot, which will make a tolerable Manure for land; and as this is a moſt troubleſome plant in many parts of England, ſo by frequently mowing, it may be deſtroyed; and when rotted, a good quantity of this Manure may be obtained, which will more than defray the charges of cutting it down. In ſome places, where no tan or horſe-dung can be obtained, they have cut down Fern and chopped it pretty ſmall, and laid it in a heap to ferment, then have uſed it for hot-beds, for which purpoſe it has anſwered pretty well. The firſt perſon who informed me of this, was Mr. Samuel Brewer, a very curious gentleman in gardening, who made ſeveral hot-beds of Fern, which, he ſays, continued their heat for ſome months; ſo that he prefers it to dung, where a moderate laſting heat is required.

There are many kinds of weeds which infeſt the lands in many parts of England, which, if cut down at a proper time and laid to rot, might be uſed to great advantage for manuring of land; and hereby the weeds may in time be deſtroyed, and the Manure would more than pay the expence of doing it: but few perſons who are employed in huſbandry care to go out of their old beaten road to try experiments, even where they are attended with little expence and nothing hazarded; otherwiſe there is great room to make improvements of this kind, eſpecially in countries where dung, or other common Manure is very ſcarce; in which places, if ſome experiments were properly made, of rotting whatever vegetables could be procured in the neighbourhood, it might turn to good account.

The aſhes of all kinds of vegetables are an excellent Manure for land, ſo that where the ground is overrun with buſhes, brambles, &c. which are become woody, if they are grubbed up in ſummer, and ſpread abroad to dry for a little time, then gently conſumed to aſhes, and theſe ſpread on the land, it will greatly improve it. The method for doing this is already explained under the article of Land.

Rotten wood, and ſaw-duſt when rotted, is a very good Manure for ſtrong land, becauſe it looſens the parts of the earth and renders it light.

Bones, horns, and other parts of animals, alſo enrich land greatly, as do decayed fiſh; ſo that in ſome places where theſe can be eaſily obtained, a great improvement may be made of them.

Sea-ſand and ſhells are in ſeveral parts of England uſed to great advantage, eſpecially in Devonſhire, where they are at the expence of fetching the ſand and ſhells on horſes backs, twelve or fourteen miles. The land on which they lay this Manure, is a ſtrong loam inclining to clay; ſo that this ſeparates the parts, and the ſalts which are contained in the dreſſing are a very great improvement of their land. Coral, and ſuch kinds of ſtony plants which grow on the rocks, are filled with ſalts which are very beneficial to land; but as theſe bodies are hard, the improvement is not the firſt or ſecond year after they are laid on the ground, becauſe they require time to pulverize them before their ſalts can mix with the earth to impregnate it. Therefore dreſſings of this kind are ſeldom uſed by tenants, who want to reap the fruit of their labour as ſoon as poſſible. But theſe Manures are much better for cold ſtrong land, than for that which is light and ſandy. In ſome countries, at a great diſtance from the ſea, have been diſcovered great quantities of foſſil ſhells, which have been dug out of the earth, and uſed as Manure, which have improved the ground a little, eſpecially ſtrong land: as theſe have little ſalts, when compared to thoſe ſhells which are taken from the ſhore, therefore where the latter can be obtained, they other are ſcarce worth uſing.

Where the land lies near the ſea, ſo that either ſand, ſhells, corals, wrecks, or ſea-weeds, can be obtained at an eaſy expence, they are by far the beſt kinds of Manure, becauſe they enrich the land for ſeveral years; for as their ſalts are cloſely locked up, they are communicated by degrees to the land, as the heat and cold cauſes the bodies to pulverize, and fall into ſmall parts; ſo that where ſand and ſmaller kinds of ſea-weeds are uſed, if they are laid on land in proper quantities it will enrich it for ſix or ſeven years; but ſhells, corals, and other hard bodies, will continue many years longer.

In dunging of land, I have frequently obſerved in ſeveral parts of England, but eſpecially in Cambridgeſhire, a very wrong cuſtom continued, by carrying and laying the dung on the land about Midſummer, and ſpread abroad perhaps a month or ſix weeks before the ground is ploughed; in which time the ſun exhales all the goodneſs of the dung, ſo that what remains is of little ſervice to the land. Therefore when dung or any other Manure is uſed, it ſhould not be laid on the ground until the laſt time of ploughing, when it ſhould be buried as ſoon as poſſible, to prevent the evaporation of the ſalts. Indeed, where ſhells, corals, or any other hard ſubſtances, are uſed for Manure, if theſe are ſpread abroad ſome months before the ground is ploughed, the ſun, rain, or froſt will cauſe them to pulverize much ſooner than when they are buried and excluded from the air.

The dreſſing of Graſs ground in ſummer, ſoon after the crop of hay is taken off the land, is equally bad; for before Michaelmas the ſun will have dried and exhaled moſt of the goodneſs, if the dreſſing is of dung or any other ſoft Manure, ſo that the ground will receive ſmall advantage from it; and yet this method is too generally practiſed.

MAPLE. See Acer.

MARACOCK. See Passiflora.

MARANTA. Plum. Nov. Gen. 16. tab. 36. Lin. Gen. Plant. 5. Indian Arrow-root.

The Characters are,

It hath a ſmall three-leaved empalement ſitting upon the germen; the flower hath one petal, which is of the grinning kind, having an oblong compreſſed tube, which is oblique and turned inward; the rim is cut into ſix ſmall ſegments, repreſenting a lip flower, the two ſide ſegments being the largeſt. It has one membranaceous ſtamina, appearing like a ſegment of the petal, with a linear ſummit faſtened to the border. It hath a roundiſh germen ſituated under the flower, ſupporting a ſimple ſtyle the length of the petal, crowned by a three-cornered ſtigma. The germen afterward turns to a roundiſh three-cornered capſule with three valves, containing one hard rough ſeed.

This genus of plants is ranged in the firſt ſection of Linnæus's firſt claſs, intitled Monandria Monogynia, which includes thoſe plants whoſe flowers have but one ſtamina and one ſtyle.

The Species are,

1. Maranta (*Arundinacea*) culmo ramoſo. Lin. Sp. 2. *Indian Arrow-root with branching ſtalks.* Maranta Arundinacea cannacori folio. Plum. Nov. Gen. 16. *Maranta with a leaf of the Indian flowering Reed.*
2. Maranta (*Galanga*) culmo ſimplici. Lin. Sp. 3. *Indian Arrow-root with a ſimple ſtalk.* Canna Indica, radice albâ alexipharmica. Sloan. Cat. Jam. 122. *Indian Arrow-root.*

The firſt ſort was diſcovered by Father Plumier in ſome of the French ſettlements in America, who gave it this name, in honour of one Bartholomew Maranta, an ancient botaniſt. The ſeeds of this kind were ſent to Europe by the late Dr. William Houſtoun, who found the plant growing in plenty near La Vera Cruz in New Spain.

This hath a thick, fleſhy, creeping root which is very full of knots, from which ariſe many ſmooth leaves, which are ſix or ſeven inches long, and three broad toward their baſe, leſſening toward each end, terminating in points. They are of the conſiſtence and colour of thoſe of the Reed, and ſtand upon Reed-like foot-ſtalks, which ariſe immediately from the root; between theſe come out the ſtalks, which riſe near two feet high; theſe divide upward into two or three ſmaller, and are garniſhed at each joint with one leaf of the ſame ſhape with the lower, but are ſmaller. The ends of the ſtalks are terminated by a looſe bunch of ſmall white flowers, ſtanding upon foot-ſtalks which are near two inches long. The flowers are cut into ſix narrow ſegments, which are indented on their edges; theſe ſit upon the embryo, which afterward turns to a roundiſh three-cornered capſule, incloſing one hard rough ſeed. It flowers here in June and July.

The other ſort was brought from ſome of the Spaniſh ſettlements in America, into the iſlands of Barbadoes and Jamaica, where it is cultivated in their gardens as a medicinal plant, it being a ſovereign remedy to cure the bite of waſps, and to extract the poiſon of the Manchineel-tree. The Indians apply the root to expel the poiſon of their arrows, which they uſe with great ſucceſs. They take up the roots, and after cleanſing them from dirt, they maſh them, and apply it as a poultice to the wounded part, which draws out the poiſon and heals the wound. It will alſo ſtop a gangrene, if it is applied before it is gone too far, ſo that it is a very valuable plant.

This ſort is very like the firſt, but has a ſingle ſtalk; the flowers are ſmaller, and the ſegments of the petals are entire, in which their principal difference conſiſts; it flowers alſo at the ſame time.

Theſe plants being natives of a warm country, are very tender, and therefore will not live in this climate, unleſs they are preſerved in ſtoves. They may be propagated by their creeping roots, which ſhould be parted in the middle of March, juſt before they begin to puſh out new leaves. Theſe roots ſhould be planted in pots filled with light rich earth, and plunged into a moderate hot-bed of tanners bark, obſerving now and then to refreſh them with water; but it muſt not be given to them in large quantities, for too much moiſture will ſoon rot the roots, when they are in an inactive ſtate. When the green leaves appear above ground, the plants will require more frequently to be watered, and they ſhould have free air admitted to them every day, in proportion to the warmth of the ſeaſon, and the heat of the bed in which they are placed. As the plants advance in ſtrength, they ſhould have a greater ſhare of air, but they muſt conſtantly remain in the ſtove plunged in the tan, otherwiſe they will not thrive; for when the pots are placed on ſhelves in the ſtove, the moiſture paſſes too ſoon from the fibres, which generally ſpread on the ſides and bottoms of the pots, ſo that the plants do not receive much nouriſhment from the water. But where they are conſtantly kept in the tanners bark, and have proper air and moiſture, they will thrive, ſo as from a ſmall root to fill the pot in which it was planted, in one ſummer. About Michaelmas the firſt ſort will begin to decay, and in a ſhort time after the leaves will die to the ground, but the pots muſt be continued all the winter in the bark-bed, otherwiſe the roots will periſh; for although they are in an unactive ſtate, yet they will not keep very long from ſhrinking, when taken out of the ground; and if the pots are taken out of the tan, and placed in any dry part of the ſtove, the roots often ſhrivel and decay; but when they are continued in the tan-bed they ſhould have but little water given to them when their leaves are decayed, leſt it rot them. The firſt ſort doth flower conſtantly in July or Auguſt, and will often produce ripe ſeeds in England; but the ſecond ſort doth not flower ſo conſtant, nor do the flowers appear ſo conſpicuous, being very ſmall and of a ſhort duration. This ſort never hath produced any ſeeds in England, nor could I ever obſerve any rudiment of a ſeed-veſſel ſucceeding the flower. The green leaves abide on this ſort moſt part of the winter, ſeldom decaying till February; and ſometimes will continue green until freſh leaves come up, and thruſt the old ones off; in which particular there is a more remarkable difference between the two ſorts, than can be obſerved in the face of plants.

MARJORAM. See Origanum.

MARLE is a kind of clay, which is become fatter, and of a more enriching quality, by a better fermentation, and by its having lain ſo deep in the earth as not to have ſpent or weakened its fertilizing quality by any product.

Marle is ſuppoſed to be much of the nature of chalk, and is believed to be fertile from its ſalt and oily quality; and that it contracts its ſalts from the air, and for that reaſon is the better the longer it is expoſed to it.

Marles are of different qualities in different counties of England. There are reckoned to be four ſorts of Marles in Suſſex, a gray, a blue, a yellow, and a red; of theſe the blue is accounted the beſt, the yellow the next, and the gray the next to that; and as for the red, that is the leaſt valuable.

The Marle in Suſſex is moſt like fullers earth, and therefore muſt certainly be the fatteſt, whereas that in the north country runs much upon the loam.

In Cheſhire they reckon ſix ſorts of Marle:

1. The cowſhut Marle, which is of a browniſh colour, with blue veins in it, and little lumps of chalk or lime ſtone; it is commonly found under clay, or low black land, ſeven or eight feet deep, and is very hard to dig.

2. Stone, ſlate, or flag Marle, which is a kind of ſoft ſtone, or rather ſlate, of a blue or bluiſh colour, that will eaſily diſſolve with froſt or rain. This is found near rivers and the ſides of hills, and is a very laſting ſort of Marle.

In Staffordſhire they eſteem the dice or ſlate Marle better than the clay Marle, and reckon the blue beſt for arable land, and the gray for paſture.

3. Peat Marle, or delving Marle, which is cloſe, ſtrong, and very fat, of a brown colour, and is found on the ſides of hills, and in wet boggy grounds, which have a light ſand in them about two feet or a yard deep. This is accounted the ſtrongeſt of all Marles, and is very good for ſandy land, but the land muſt have a double quantity laid on.

4. Clay Marle; this reſembles clay, and is pretty near akin to it, but is fatter, and ſometimes mixed with chalk ſtones.

5. Steel Marle, which lies commonly in the bottom of pits that are dug, and is of itſelf apt to break into cubical bits; this is ſometimes under ſandy land.

6. Paper Marle, which reſembles leaves or pieces of brown paper, but ſomething of a lighter colour; this lies near coals. This ſort is leſs eſteemed, it being hard to be got.

The properties of any ſorts of Marles, and by which the goodneſs of them may be beſt known, are better judged of by their purity and uncompoundedneſs, than their colour: as if it will break in pieces like dice, or into thin flakes, or is ſmooth like lead ore, and is without a mixture of gravel or ſand; if it will ſhake like ſlate ſtones, and ſhatter after wet, or will turn to duſt when it has been expoſed to the ſun: or will not hang and ſtick together when it is thoroughly dry, like tough clay; but is fat and tender, and will open the land it is laid on, and not bind; it may be taken for granted, that it will be beneficial to it.

Some adviſe to try the goodneſs of Marle, by putting ſome of it in a glaſs of water; and they account it to be good, if it be ſo tender, that the lumps break, and diſſolve as ſoon as it comes to the bottom; they alſo reckon it a good ſign, if it ſparkle in the water, and feel fat between the fingers; but the ſureſt ſign of its goodneſs is, if it diſſolve by wet or froſt. The ſtrength of Marle may alſo be known, by putting a lump of it in a glaſs of good vinegar, where, if the fermentation is great, it is a ſure ſign of the goodneſs of the Marle.

Some approve of marling land ſhallow, becauſe they ſay, it is apt to work downwards; others of laying it in deep at firſt, becauſe the ſun waſtes the fatneſs of it.

Some recommend Marles for the improving of ſandy looſe land, but the ſureſt way to know what lands it will beſt ſuit with, is to try with a little of it on lands ſuppoſed to be of a contrary nature to it.

Marles do not make ſo good an improvement of lands the firſt year as afterwards.

Some adviſe, firſt to burn the Marle before it is laid on the lands; which if it be done, one load will go as far as five.

The quantity of Marle ought to be in proportion to the depth of the earth, for over-marling has often proved of worſe conſequence than under-marling, eſpecially where the land is ſtrong; for by laying it in too great quantities, or often repeating the marling, the land has become ſo ſtrong, and bound ſo cloſely, as to detain the wet like a diſh, ſo that the owners have been obliged to drain the ground at a great expence, and have often been obliged to lower their rents; but in ſandy land there can be no danger in laying on a great quantity, or repeating it often, for it is one of the beſt dreſſings for ſuch land.

MARRUBIASTRUM, Baſtard Horehound. See Sideritis.

MARRUBIUM. Tourn. Inſt. R. H. 192. tab. 91. Lin. Gen. Plant. 640. Pſeudodictamnus. Tourn. 188. tab. 89. Lin. Gen. Plant. 640. [ſome derive the name of מרוב, *Heb.* Marrob, i. e. bitter juice; others from the Latin word Marcidum, becauſe the leaves of this plant are ſo wrinkled, that they appear to be withering.] Horehound.

The Characters are,

The empalement of the flower is funnel-ſhaped, of one leaf, and equal at the brim, which ſpreads open. The flower is of the lip or grinning kind, with a cylindrical tube opening at the brim, where it is divided into two lips, the upper being very narrow and acute, the under broad, reflexed, and cut into three ſegments, the middle one is broad and indented. It has four ſtamina, which are under the upper lip, two of which are a little longer than the other, terminated by ſimple ſummits. It hath a four-pointed germen, ſupporting a ſlender ſtyle of the ſame length, and ſituated with the ſtamina, crowned by a bifid ſtigma. The germen afterward turns to four oblong ſeeds, ſitting in the empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's fourteenth claſs, intitled Didynamia Gymnoſpermia, which includes thoſe plants whoſe flowers have two long and two ſhort ſtamina, which are ſucceeded by naked ſeeds ſitting in the empalement.

The Species are,

1. **Marrubium** (*Vulgare*) dentibus calycinis ſetaceis uncinatis. Hort. Cliff. 312. *Horehound with hooked briſtly indentures to the empalement.* Marrubium album vulgare. C. B. P. 230. *Common white Horehound.*

2. **Marrubium** (*Peregrinum*) foliis ovato-lanceolatis ſerratis, calycum denticulis ſetaceis. Hort. Cliff. 311. *Horehound with oval, ſpear-ſhaped, ſawed leaves, and briſtly indentures to the empalement.* Marrubium album latifolium peregrinum. C. B. P. 230. *Broad-leaved, foreign, white Horehound.*

3. **Marrubium** (*Creticum*) foliis lanceolatis dentatis, verticillis minioribus, dentibus calycinis ſetaceis erectis. *Horehound with ſpear-ſhaped indented leaves, ſmaller whorls, and erect briſtly indentures to the empalements.* Marrubium album anguſtifolium peregrinum. C. B. P. 230. *Narrow-leaved, foreign, white Horehound.*

4. **Marrubium** (*Alyſſon*) foliis cuneiformibus, quinque verticillis involucro deſtitutis. Hort. Cliff. 311. *Horehound with wedge-ſhaped plaited leaves, with five indentures, and the whorls deſtitute of covers.* Marrubium alyſſon dictum, foliis profundè inciſis. H. L. *Horehound, called Madwort, with leaves which are deeply cut on their ſides.*

5. **Marrubium** (*Supinum*) dentibus calycinis ſetaceis rectis villoſis. Hort. Cliff. 312. *Horehound with hairy, erect, briſtly indentures to the empalement.* Marrubium Hiſpanicum ſupinum, foliis ſericeis argenteis. Tourn. 193. *Low Spaniſh Horehound with ſilken ſilver-coloured leaves.*

6. **Marrubium** (*Candidiſſimum*) foliis ſubovatis lanatis ſupernè emarginato-crenatis, denticulis calycinis ſubulatis. Hort. Cliff. 312. *Horehound with woolly leaves almoſt oval, the upper parts of which are indented and crenated, with awl-ſhaped indentures to the empalements.* Marrubium album candidiſſimum & villoſum. P. 222. *Baſtard Dittany, with a pan or hollow of Molucca Baum.*

The firſt ſort is the Praſium, or white Horehound of the ſhops. This grows naturally in moſt parts of England, ſo is ſeldom propagated in gardens. It hath a ligneous fibrous root, from which come out many ſquare ſtalks a foot or more in length, which branch out upward, and are garniſhed with hoary roundiſh leaves, indented on the edges, placed oppoſite. The flowers grow in very thick whorls round the ſtalks at each joint; they are ſmall, white, and of the lip kind, ſtanding in ſtiff hoary empalements, cut into ten parts at the top, which end in ſtiff briſtles; theſe are ſucceeded by four oblong black ſeeds ſitting in the empalement. It flowers in June, and the ſeeds ripen in autumn.

The ſecond ſort grows naturally in Italy and Sicily; this riſes with ſquare ſtalks near three feet high, which branch much more than the firſt; the leaves are rounder, whiter, and ſtand farther aſunder; the whorls of flowers are not ſo large, but the flowers have longer tubes.

The third ſort grows naturally in Spain and Portugal; this riſes with ſlender hoary ſtalks near three feet high; the leaves are very hoary, much longer and narrower than thoſe of the ſecond; the whorls of flowers are ſmaller, the briſtly indentures of the empalements are longer and erect; the whole plant has an agreeable flavour.

The fourth ſort grows naturally in Spain and Italy; this is a biennial plant, whoſe ſtalks are about the ſame length as thoſe of the firſt; the leaves are wedge-ſhaped, hoary, and obtuſely indented; the whorls of flowers are ſmall, and have no covers. The flowers ſtand looſer in the whorls, and the cuts of the empalement end in very ſtiff prickles, which ſpread open; the flowers are purple, and larger than thoſe of the firſt ſort.

The fifth ſort grows naturally in the iſlands of the Archipelago; the ſtalks of this are ſeldom above eight or nine inches long, covered with a ſoft hoary down; the leaves are ſmall, roundiſh, and very ſoft to the touch; they are hoary, and indented on the edges. The whorls of flowers are ſmall, very downy, and white; the flowers are ſmall and white.

The ſixth ſort grows naturally in Spain; this hath ſtalks about the ſame length as the firſt; the leaves are nearly oval, woolly, and crenated toward the top, and the empalement of the flowers are awl-ſhaped.

The ſeventh ſort grows naturally in Iſtria, from whence I received the ſeeds. The ſtalks of this grow more erect than thoſe of the common ſort: the leaves are rounder and more ſawed on the edges; the empalement of the flowers ſpread open, ending in acute ſegments. The flowers are like thoſe of the common ſort; the whole plant is very hoary.

The eighth ſort grows naturally in Spain and Sicily; this ſends out many ſtiff roundiſh ſtalks, which riſe more than two feet high, covered with a white cottony down; the leaves are almoſt round, rough on their upper ſide, and woolly on their under; the whorls of flowers are large, the borders of the empalement are flat and hairy; the tube of the flower is ſcarce ſo long as the empalement, ſo the two lips are but juſt viſible.

The ninth ſort grows naturally in Spain; the ſtalks of this are ſhrubby, and riſe near three feet high, dividing into ſmall branches; the leaves are heart-ſhaped and rough on their upper ſide, but hoary on their under; the whorls of flowers are large, the borders of the empalements flat and hairy; the tube of the flower is longer, and the flowers are larger than thoſe of the former ſort; they are of a pale purple colour, and their upper lips are erect.

The tenth ſort grows naturally in Sicily, and the Iſlands of the Archipelago. This riſes with a ſhrubby ſtalk two feet high, which divides into many branches, garniſhed with ſmall heart-ſhaped leaves, ſitting pretty cloſe to the ſtalks: the whorls of flowers are not ſo large as thoſe of the two former ſorts. The rim of the empalements are flat. The flowers are white, and the whole plant is very hoary.

The eleventh ſort grows naturally in Crete; this hath very hairy ſtalks which riſe about two feet high, garniſhed with heart-ſhaped leaves, which are rough on their upper ſide, but hoary on their under. The whorls of flowers are large, the border of the empalements flat, and cut into many ſegments, which are membranaceous, angular, and rounded at the top. The flowers are ſmall, of a pale purple colour, but ſcarce appear out of their empalements, and their upper lips are erect.

The firſt ſort is what the College of Phyſicians has directed to be uſed in medicine. The leaves and tops of the plants are eſteemed hot and dry, pectoral, and good to free the lungs from thick viſcid phlegm, and thereby to help old coughs, eſpecially in cold moiſt conſtitutions, the juice being made into a ſyrup with ſugar or honey; they open obſtructions of the liver and ſpleen, and are very ſerviceable againſt the dropſy, jaundice, green ſickneſs, and obſtructions of the catamenia, and ſuppreſſion of the lochia, and other diſtempers of the female ſex, for which few herbs go beyond this. The officinal preparation is the ſyrupus de Praſſio.

The fourth ſort is ſuppoſed to be Galen's Madwort; this was by the antients greatly recommended for its efficacy in curing of madneſs, and ſome few of the moderns have preſcribed it in the ſame diſorder, but at preſent it is ſeldom uſed; it is a biennial plant, which generally periſhes after it hath perfected ſeeds.

All theſe plants are preſerved in botanic gardens for the ſake of variety, but there are not above two of the ſorts which are cultivated in other gardens; theſe are the tenth and eleventh ſorts, whoſe ſtalks are ſhrubby; the plants are very hoary, ſo make a variety when intermixed with other plants; theſe very rarely produce ſeeds in England, ſo are propagated by cuttings, which, if planted in a ſhady border the middle of April, will take root pretty freely.

They are ſomewhat tender, ſo in very ſevere winters are killed, unleſs they are ſcreened from the hard froſts, eſpecially thoſe plants which grow in good ground, where they grow luxuriant in ſummer, ſo their branches are more replete with juice, and very liable to ſuffer by cold; but when they are in a poor dry rubbiſh, the roots will be ſhort, firm, and dry, ſo are ſeldom injured by cold, and will continue much longer than thoſe in better ground.

The other ſorts are eaſily propagated by ſeeds, which ſhould be ſown on a bed of poor earth in the ſpring, and when the plants come up they muſt be kept clean from weeds; and where they are too cloſe they ſhould be thinned, leaving them a foot and a half aſunder, that their branches may have room to ſpread; after this they require no other culture; they may alſo be propagated by cuttings, in the ſame manner as the other two ſorts. If theſe plants are upon a dry poor ſoil, they will live ſeveral years, but in rich land they ſeldom laſt above three or four.

MARRUBIUM NIGRUM. See Ballote.

MARTAGON. See Lilium.

MARTYNIA. Houſt. Gen. Nov. Martyn. Dec. 1. 42. [This name was given by the late Dr. William Houſtoun to this genus of plants, which he diſcovered in America, in honour of his friend Mr. John Martyn, who was Profeſſor of Botany at Cambridge.]

The Characters are,

The empalement of the flower is cut into five parts, three of them are erect, and two reflexed. The flower hath one petal, which is bell-ſhaped, with a large ſwelling tube, at the baſe of which is ſituated a gibbous nectarium. The rim of the petal is cut ſlightly into five obtuſe ſegments, two of which are turned upward, the other three downward, repreſenting a lip flower. It hath four ſlender incurved ſtamina, which are inflexed into each other, terminated by ſummits, which are connected together. It hath an oblong germen ſituated under the flower, ſupporting a ſhort ſtyle, crowned by a plain ſtigma. The empalement afterward turns to an oblong gibbous capſule, which divides into two parts, including a hard nut, ſhaped like the body of a ſtag beetle, with two incurved ſtrong horns at the end, having four cells, two of which are generally barren, the other two have one oblong ſeed in each.

This genus of plants is ranged in the ſecond ſection of Linnæus's fourteenth claſs, which includes the plants whoſe flowers have two long and two ſhort ſtamina, and the ſeeds are included in a capſule.

The Species are,

1. Martynia (*Annua*) caule ramoſo, foliis angulatis. Lin. Sp. Plant. 618. *Martynia with a branching ſtalk and angular leaves.* Martynia annua villoſa & viſcoſa, folio ſubrotundo, flore magno rubro. Houſt. *Annual, hairy, viſcous Martynia, with a roundiſh leaf, and a large red flower.*
2. Martynia (*Perennis*) caule ſimplici, foliis ſerratis. Lin. Sp. Plant. 618. *Martynia with a ſingle ſtalk and ſawed leaves.* Martynia foliis ſerratis. Lin. Hort. Cliff. *Martynia with ſawed leaves.*
3. Martynia (*Louiſiana*) caule decumbente ramoſa, foliis integris fructibus longiſſimis. *Martynia with a decumbent branching ſtalk, entire leaves, and very long fruit.*

The firſt of theſe plants was diſcovered by the late Dr. William Houſtoun, near La Vera Cruz, in New Spain, from whence he ſent the ſeeds into England, which ſucceeded very well in the Phyſic Garden at Chelſea; and in the year 1731, ſeveral of theſe plants were raiſed, which produced their beautiful flowers, and perfected their ſeed, from whence ſeveral plants were raiſed the ſucceeding year.

This riſes with a ſtrong, herbaceous, hairy ſtalk near three feet high, which divides upward into three or four large branches, garniſhed with oblong oval leaves, cut into angles on their ſides; they are five inches long, and three inches and a half broad at their baſe, where they are broadeſt, ending in obtuſe points; they are hairy, and very viſcous, ſticking to the fingers if handled. The flowers are produced in ſhort ſpikes from the forks of the branches, and alſo at their tops; they are ſhaped like thoſe of the Foxglove, but are of a paler purple colour; theſe are ſucceeded by oblong oval capſules, which are thick, tough, and clammy; theſe, when ripe, divide into two parts, leaving a large hard nut hanging on the plant, about the ſize, and much of the ſame form, as the ſtag beetle, with two ſtrong crooked horns at the end. The nut has two deep longitudinal furrows on the ſides, and ſeveral ſmaller croſſing each other in the middle. It is ſo hard, that it is with difficulty cut open without injuring of the ſeeds: within are four oblong cells, two of which have generally a ſingle oblong ſeed in each, but the other two are abortive. If the plants are brought forward in the ſpring, they will begin to ſhew their flowers in July, which are firſt produced at the diviſion of the branches, and afterward at the extremity of each branch, ſo there will be a ſucceſſion of flowers on the ſame plant till the end of October, when the plants decay.

The ſecond ſort was diſcovered by Mr. Robert Millar, growing naturally about Carthagena in New Spain, from whence he ſent the ſeeds to Europe; this hath a perennial root and an annual ſtalk, which decays every autumn, and new ones ariſe in the ſpring. The roots of this plant are thick, fleſhy, and divided into knots, which are ſcaly, ſomewhat like thoſe of Toothwort; theſe ſend up ſeveral ſtalks, which grow about a foot high; they are thick, ſucculent, and of a purpliſh colour, garniſhed with oblong thick leaves, whoſe baſe ſits cloſe to the ſtalk; they are ſawed on their edges, rough on their upper ſide, where they are of a dark green, but their under ſide is purpliſh. The ſtalk is terminated by a ſhort ſpike of blue flowers, which are bell-ſhaped, and do not ſpread open at the rim ſo much as the former ſort; theſe uſually appear in July or Auguſt, but are not ſucceeded by ſeeds in England.

The firſt ſort, being an annual plant, is only propagated by ſeed, which ſhould be ſown in pots filled with light rich earth, and plunged into a hot-bed of tanners bark, where (if the earth is duly watered to promote the vegetation of the ſeed) the plants will appear in about three weeks or a month, and will grow pretty faſt if the bed is warm; they ſhould therefore be tranſplanted in a little time after they come up, each into a ſeparate pot filled with light rich earth, and then plunged into the hot-bed again, obſerving to water them well, as alſo to ſhade them from the ſun until they have taken new root; after which time they ſhould have a large ſhare of freſh air admitted to them in warm weather, by raiſing the glaſſes of the hot-bed every day: with this management the plants will make great progreſs, ſo as to fill the pots with their roots in about a month or ſix weeks time, when they ſhould be ſhifted into pots about a foot diameter at the top, which ſhould be filled with light rich earth, and then plunged into the hot-bed in the bark-ſtove, where they ſhould be allowed room, becauſe they put out many ſide branches, and will grow three feet high or more, according to the warmth of the bed, and the care which is taken to ſupply them conſtantly with water; and ſhould be conſtantly kept in the tan-bed, giving them plenty of free air at all times when the weather is warm, but they will not bear to be expoſed abroad in this country; when theſe plants thrive well they will ſend out many ſide branches, which will all of them produce ſmall ſpikes of flowers; but it is only from the firſt ſpike of flowers that good ſeeds can be expected in this country, ſo that particular care ſhould be taken, that none of theſe are pulled off or deſtroyed, becauſe it is very difficult to obtain good ſeeds here; and I believe few of thoſe that are produced on the ſide branches in the natural country of their growth, are duly ripened; for I have received a great quantity of theſe ſeeds from abroad, which have appeared to be very good, and yet few of them have grown.

The ſeeds of theſe plants have a ſtrong green covering on them, as thick as the outer covering of an Almond, and when the ſeeds are ripe, the covering opens, and lets the ſeeds fall, in the ſame manner as the covering of Almonds, Walnuts, &c. In each covering there is one hard nut, in ſhape ſomewhat like a beetle, having two ſharp crooked horns at one end. This nut contains four embryos, but there are ſeldom more than two ſeeds which are perfect in any of them. However, when they are ſown, the whole nut muſt be planted, for it is ſo hard, that it is almoſt impoſſible to take out the ſeeds without ſpoiling them; ſo where there are two plants produced from the ſame nut, they are eaſily ſeparated, eſpecially if they are tranſplanted while young. Theſe ſeeds will continue good for ſome years, for I ſaved a pretty large quantity of them in the year 1734, part of which I ſowed the following year, but had not one plant produced from them; the remainder of the ſeeds I divided, and ſowed ſome of them every ſucceeding year, without any ſucceſs, until the year 1738, when I ſowed all the ſeeds I had left, from which I had one plant produced; ſo that if the ſeeds are good, it is evident they will grow when they are four years old; therefore, whenever we receive good ſeeds from abroad, or ſave any in this country which are perfectly ripened, it will be proper to preſerve ſome of them for a year or two, leſt a bad ſeaſon ſhould happen, when the plants may not perfect their ſeeds; ſo that if this precaution be not taken, the ſpecies may be loſt in Europe.

The ſecond ſort dies to the root every winter, and riſes again the ſucceeding ſpring; this muſt be conſtantly preſerved in the ſtove, and plunged into the bark-bed, otherwiſe it will not thrive in this country. During the winter ſeaſon, when the plants are decayed, they ſhould have but little water given to them, for at that time it will rot the roots. In the middle of March, juſt before the plants begin to ſhoot, is the proper ſeaſon to tranſplant and part the roots, when they ſhould be planted into pots of a middle ſize, filled with light rich earth, and then plunged into the bark-bed, which ſhould at this time be renewed with ſome freſh tan. When the plants come up, they muſt be frequently refreſhed with water, but it muſt not be given to them in large quantities, leſt it rot their tender roots; and as the warmth of the ſeaſon increaſes, it will be proper to admit a large ſhare of freſh air, which will greatly ſtrengthen the plants; they muſt alſo be placed in the tan-bed, where they are not over-hung, or ſhaded by other plants; nor ſhould they be ſhifted or tranſplanted when they are in leaf, for that will prevent their flowering. As the roots of this plant increaſe very faſt, there is no neceſſity for uſing other methods to propagate it; otherwiſe the ſhoots of the young ſtalks will take root, if they are planted in pots filled with light earth, and plunged into a hot-bed during any of the ſummer months.

The third ſort grows naturally in Louiſiana, from whence the ſeeds were brought to France. This is an annual plant, having a ſucculent viſcous ſtalk, which divides into many branches; theſe thick ſucculent ſtalks become too weighty for the ſtalk to ſupport them, whereby the ſtalk generally is brought to the ground, unleſs it is well ſupported: the leaves are large, viſcous, and hairy; ſome of them are cut into angles, but for the moſt part they are entire, five or ſix inches long, and four broad in the middle. The flowers are produced from the forks of the ſtalk in ſhort ſpikes; they are of a pale red colour, and in ſhape and ſize like thoſe of the firſt ſort; they are ſucceeded by fruit four or five inches long, having a thick green cover, which parts and falls off when ripe, leaving a rough beetle-ſhaped veſſel, having two very long horns at the end, opening in two parts, containing ſeveral oval ſeeds, covered with a black ſkin, which muſt be taken off before the ſeeds are ſown.

This being an annual plant, ſhould be brought forward in the ſpring, by ſowing the ſeeds on a hot-bed the latter end of March; and when the plants come up, they ſhould be treated almoſt in the ſame manner as the firſt, with this difference only, that being more hardy than the firſt, the plants ſhould have more air admitted to them, to prevent their drawing up weak; nor ſhould they have too much water in ſummer, which is apt to rot their ſucculent ſtems before the ſeeds are perfected.

MATRICARIA. Tourn. Inſt. R. H. 493. tab. 281. Lin. Gen. Plant. 867. [ſo called from the matrix, becauſe this plant is very good againſt diſeaſes of the womb; and for the ſame reaſon it is called Parthenium, of Παρθένος, a virgin.] Feverfew; in French, *Matricaire.*

The Characters are,

It hath a compound flower. The ray, or border, is compoſed of many female half florets, and the diſk, which is hemiſpherical, of hermaphrodite florets; theſe are included in one common hemiſpherical empalement, compoſed of linear ſcales, nearly equal. The female half florets are tongue-ſhaped, and indented in three parts at the end; theſe have a naked germen, ſupporting a ſlender ſtyle, terminated by two twiſted ſtigmas. The hermaphrodite florets are tubulous, funnel-ſhaped, and cut into five parts at the brim, which ſpread open; they have each five hairy ſhort ſtamina, terminated by cylindrical ſummits, and an oblong naked germen, with a ſlender ſtyle, crowned by a bifid ſpreading ſtigma. The germen of both turn to ſingle, oblong, naked ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's nineteenth claſs, which includes the plants with compound flowers, whoſe ſtamina and ſtyles are connected, and the florets are all fruitful.

The Species are,

1. Matricaria (*Parthenium*) foliis compoſitis planis, foliolis ovatis inciſis, pedunculis ramoſis. Hort. Cliff. 416. *Feverfew with plain compounded leaves, whoſe lobes are oval and cut, having branching foot-ſtalks.* Matricaria vulgaris, ſeu ſativa. C. B. P. 133. *Common, or Garden Feverfew.*
2. Matricaria (*Maritima*) receptaculis hemiſphæricis, foliis bipinnatis ſubcarnoſis, ſuprà convexis, ſubtus carinatis. Lin. Sp. Plant. 891. *Feverfew with hemiſpherical receptacles, doubly winged leaves, which are fleſhy, and convex on their upper ſide, but keel-ſhaped below.* Chamæmelum maritimum perenne humilius, foliis

brevoribus

brevioribus craſſis obſcurè virentibus. Raii Syn. Ed. 3. p. 186. *Dwarf, perennial, maritime Chamomile, with ſhort, thick, dark green leaves.*

3. Matricaria (*Indica*) foliis ovatis ſinuatis angulis ſerratis acutis. *Feverfew with oval, ſinuated, angular, acutely-ſawed leaves.* Matricaria latiore folio, flore pleno. Mor. Hiſt. 3. p. 33.

4. Matricaria (*Argentea*) foliis bipinnatis, pedunculis ſolitariis, Hort. Cliff. 415. *Feverfew with winged leaves, and ſingle foot-ſtalks to the flowers.* Chamæmelum Orientale incanum, Millefolium folio. Tourn. Cor. 37.

5. Matricaria (*Americana*) foliis lineari-lanceolatis integerrimis, pedunculis unifloris. *Feverfew with entire ſpear-ſhaped leaves, and foot-ſtalks with one flower.*

The firſt ſort is the common Feverfew, which is directed to be uſed in medicine. It grows naturally in lanes, and upon the ſide of banks in many parts of England, but is frequently cultivated in the phyſic-gardens to ſupply the markets; this is commonly a biennial plant, which decays ſoon after it has perfected ſeeds. The root of this plant is compoſed of a great number of fibres, which ſpread wide on every ſide. The ſtalks riſe upward of two feet high; they are round, ſtiff, and ſtriated, branching out on every ſide. The leaves are compoſed of ſeven lobes, which are cut into many obtuſe ſegments; they are of a yellowiſh green colour. The ſtalks and branches are terminated by the flowers, which are diſpoſed almoſt in the form of looſe umbels, each flower ſtanding upon a ſeparate foot-ſtalk, about two inches long. The flowers are compoſed of ſeveral ſhort rays, which are white, like thoſe of the Chamomile, ſurrounding a yellow diſk, compoſed of hermaphrodite florets, which form a hemiſphere; theſe are incloſed in one common ſcaly empalement, and are ſucceeded by oblong, angular, naked ſeeds. It flowers in June, and the ſeeds ripen in autumn. The whole plant has a ſtrong unpleaſant odour. The leaves and flowers of this are uſed in medicine, and are particularly appropriated to the female ſex, being of great ſervice in all cold flatulent diſorders of the womb, and hyſteric affections, procuring the catamenia, and expelling the birth and ſecundines.

The following varieties of this plant are preſerved in botanic gardens, many of which are pretty conſtant, if care is taken in ſaving the ſeeds; but where the ſeeds of theſe plants has been ſuffered to ſcatter, it will be almoſt impoſſible to preſerve the varieties without mixture; but if the ſeeds are ſown upon a freſh ſpot of ground, where there has not grown any of the plants before, I am inclinable to believe the ſeeds will produre the ſame plants as thoſe they were taken from; however, as they are ſuppoſed to be only varieties, ſo I ſhall only juſt inſert them here, for the uſe of thoſe who are curious in collecting the varieties.

1. Feverfew with very double flowers.
2. Feverfew with double flowers, whoſe borders, or rays are plain, and the diſk fiſtular.
3. Feverfew with very ſmall rays.
4. Feverfew with very ſhort fiſtular florets.
5. Feverfew with naked heads, having no rays or border.
6. Feverfew with naked ſulphur-coloured heads.
7. Feverfew with elegant curled leaves.

Theſe plants are all propagated by their ſeeds, which ſhould be ſown in March upon a bed of light earth, and, when they are come up, they ſhould be tranſplanted out into nurſery-beds, at about eight inches aſunder, where they may remain till the middle of May, when they may be taken up, with a ball of earth to their roots, and planted in the middle of large borders, where they will flower in July and Auguſt; and, if the autumn be favourable, will produce ripe ſeeds the ſame year. But it is not adviſeable to permit them to ſeed, which often weakens and decays the roots; therefore, when their flowers are paſt, you ſhould cut down their ſtems, which will cauſe them to puſh out freſh heads, whereby the roots may be maintained.

When the different varieties of theſe plants are intermixed with other plants of the ſame growth, they make a handſome appearance during the ſeaſon of flowering, which commonly continues a full month, or more, which renders them more valuable. But as their roots ſeldom abide more than two, or at moſt three years, freſh plants would be raiſed from ſeeds to ſupply their places; for although they may be propagated by parting their roots either in ſpring or autumn, yet theſe ſeldom make ſo good plants as thoſe obtained from ſeeds; but the ſecond variety ſeldom produces any good ſeeds, therefore that muſt be propagated in this manner, or by planting cuttings in the ſpring or ſummer months, which will take root, and make good plants.

The ſecond ſort grows naturally near the ſea, in ſeveral parts of England. I have obſerved it upon the Suſſex coaſt in great plenty, from whence I brought the plants, which were of no longer duration in the garden than two years, though in their native ſoil they may continue longer. The ſtalks of this plant branch out pretty much, and ſpread near the ground; they are garniſhed with dark green leaves, which are compoſed of many double wings, or pinnæ, like thoſe of the common Chamomile, but are much thicker in ſubſtance; they have their edges turned backward, ſo are convex on their upper ſurface, and concave on their under. The flowers are white, like thoſe of the common Chamomile, and are diſpoſed almoſt in the form of an umbel; they appear in July, and the ſeeds ripen in autumn.

This plant is ſeldom cultivated but in botanic gardens for variety. It may be propagated by ſeeds, which may be ſown either in autumn, ſoon after they are ripe, or in the ſpring, upon a bed of common earth, in almoſt any ſituation; and when the plants come up, they will require no other care but to thin them where they are too cloſe, and keep them clean from weeds.

The third ſort grows naturally in many parts of India, I received it from Nimpu, where it grows plentifully; this plant riſes a foot and a half high, dividing into many branches, garniſhed with angular oval leaves, which are acutely ſawed on their edges, and are of a pale colour; the flowers are produced on foot-ſtalks which ariſe from the wings of the leaves, and alſo terminate the branches; theſe are, in all I have yet ſeen, very double, and full as large as thoſe of the double ſort before-mentioned; theſe appear in July, and in favourable ſeaſons are ſucceeded by ſeeds which ripen late in the autumn.

This ſort is propagated by ſeeds, which ſhould be ſown in the ſpring upon a moderate hot-bed, and when the plants come up, they muſt be treated in the manner already directed for the Chryſanthemum Coronarium, with which culture they will thrive and flower very well.

The fourth ſort grows naturally in the eaſt; this ſort riſes a foot high, having winged leaves of a ſilver colour, which are for the moſt part placed oppoſite; the foot-ſtalks of the flowers ariſe ſingle from the ſide of the branches, each ſupporting one white flower. This flowers in July, and in warm ſeaſons will ſometimes perfect ſeeds in autumn.

The ſeeds of this ſort ſhould be ſown in April, on a bed of light earth, in a good expoſure; and when the plants are grown of a proper ſize to remove, they ſhould be planted in the borders of the flower-garden; where, if they are kept clean from weeds, they will flower and perfect their ſeeds.

The fifth ſort grows naturally in North America; this is a perennial plant, whoſe ſtalks and leaves decay in the autumn, and new ones come out again in the ſpring; the ſtalks riſe a foot and a half high, and divide upward into ſeveral forked branches; at each of theſe diviſions is placed one linear ſpear-ſhaped leaf about two inches long, and a quarter of an inch broad, entire on the edges, and of a deep green. The branches are terminated by ſingle foot-ſtalks, each ſupporting one blue flower, very like thoſe of ſome kind of Starwort; but the empalement being ſcaly, and the ſeeds having no down, occaſions its being here placed. The flowers appear in July and Auguſt, and the ſeeds ripen in the autumn.

This is propagated by ſeeds, which, if ſown in the autumn, ſoon after they are ripe, will more certainly ſucceed than when ſown in the ſpring; they ſhould be ſown in the full ground, and when the plants are fit to remove, if they are planted in the borders of the flower-garden, they will continue ſome years without protection, and annually produce flowers and ſeeds.

MATTED ROOTS are ſuch as are entangled or plaited together.

MAUDLIN. See ACHILLEA.

MAUROCENIA. Lin. Gen. Plant. Edit. 2. 289. Frangula. Hort. Elth. 121. The Hottentot Cherry, vulgo.

The CHARACTERS are,

The empalement of the flower is of one leaf, cut into five ſegments, and is permanent. The flower hath five oval petals, which ſpread open. It hath five ſtamina, which are ſituated between the petals, crowned by obtuſe ſummits. In the center is ſituated a roundiſh germen, having no ſtyle, crowned by a trifid ſtigma. The germen afterward turns to an oval berry with one or two cells, each containing a ſingle oval ſeed.

This genus of plants is ranged in the third ſection of Linnæus's fifth claſs, which includes the plants whoſe flowers have five ſtamina and three ſtyles or ſtigmas; and in the laſt edition of his Genera, he has joined it to the Caſſine, making them the ſame; but as the flower of Caſſine has but one petal, and the flower of theſe have five; and the berries of the former three cells, and thoſe of this but one or two, therefore I have ſeparated them.

The SPECIES are,

1. MAUROCENIA (*Frangula*) foliis ſubovatis integerrimis, floribus confertis lateralibus. *Maurocenia with entire leaves which are almoſt oval, and flowers growing in cluſters on the ſides of the branches.* Frangula ſempervirens, folio rigido ſubrotundo. Hort. Elth. 146. tab. 121. *Evergreen berry-bearing Alder with a roundiſh ſtiff leaf, commonly called Hottentot Cherry.*
2. MAUROCENIA (*Phillyrea*) foliis obverſè ovatis ſerratis, floribus corymboſis alaribus & terminalibus. *Maurocenia with obverſe, oval, ſawed leaves, and flowers growing in a corymbus at the ſides and ends of the branches.* Phillyrea capenſis, folio celaſtri. Hort. Elth. 315. tab. 236. *Phillyrea of the Cape with a Staff-tree leaf, by the Dutch called Leplebout.*
3. MAUROCENIA (*Ceraſus*) foliis ovatis nervoſis integerrimis. *Maurocenia with oval veined leaves, which are entire.* Ceraſus Hottentotorum. Pluk. Almag. 94. *The ſmaller Hottentot Cherry.*
4. MAUROCENIA (*Americana*) foliis obverſè ovatis emarginatis, floribus ſolitariis alaribus. *Maurocenia with obverſe oval leaves which are indented at the edges, and flowers growing ſingly from the ſides of the branches.* Frangula folio ſubrotundo rigido ſubtus ferrugineo. Houſt. MSS. *Berry-bearing Alder with a roundiſh ſtiff leaf, which is of an iron colour on the under ſide.*

The firſt ſort grows naturally at the Cape of Good Hope, where it riſes to a conſiderable height, but here they are rarely more than five or ſix feet high. The ſtalk is ſtrong, woody, and covered with a purpliſh bark, ſending out many ſtiff branches, garniſhed with very thick leaves, almoſt oval, ſtanding for the moſt part oppoſite; they are about two inches long, and almoſt as much in breadth, of a dark green colour, and entire. The flowers come out from the ſide of the old branches, in cluſters, three, four, or five, ſtanding upon one common foot-ſtalk, which is ſlender, compoſed of five plain equal petals, ending in acute points; they are firſt of a greeniſh yellow colour, but afterward change to white, ſpreading wide open. In the center is ſituated the oval germen, crowned by the trifid ſtigma, and between each petal is ſituated a ſtamina; theſe ſpread open in the ſame manner as the petals, and are terminated by obtuſe ſummits. The germen afterward turns to an oval pulpy berry, ſome having but one, and others two cells; in each of theſe is lodged one oval ſeed. The berries change to a dark purple when they are ripe. This plant flowers in July and Auguſt, and the berries ripen in winter.

The ſecond ſort is a native of the Cape of Good Hope; this hath a woody ſtalk, which in this country ſeldom riſes more than five or ſix feet high, ſending out many branches, covered with a dark purpliſh bark, and garniſhed with pretty ſtiff leaves, which are obverſely oval, and ſawed on their edges, ſtanding oppoſite; they are about an inch and a half long, and a little more in breadth, of a light green, having ſhort foot-ſtalks. The flowers are produced in roundiſh bunches from the ſide, and at the end of the branches; they are white, and have five ſmall petals which ſpread open; between theſe are ſituated the ſtamina, which ſpread in the ſame manner; theſe are terminated by obtuſe ſummits. In the center is ſituated the roundiſh germen, which is crowned ſometimes by a bifid, and at others by a trifid ſtigma. The flowers appear in July and Auguſt, but are not ſucceeded by berries in England.

The third ſort grows naturally at the Cape of Good Hope; this riſes with a woody ſtalk about the ſame height as the former, dividing into many branches, which are garniſhed with ſtiff oval leaves about two inches long, and nearly as much in breadth, of a lucid green colour, and entire, having three longitudinal veins; theſe are ſometimes placed oppoſite, and at others they are alternate, having a ſtrong margin, or border, ſurrounding them. This ſort hath produced its flowers in England, and I am fully convinced that the characters of the flowers are the ſame with the others.

The fourth ſort was diſcovered by the late Dr. Houſtoun, growing naturally at the Paliſadoes in Jamaica, from whence he ſent the ſeeds to Europe; this riſes with a woody ſtalk from fifteen to twenty feet high, covered with a rough brown bark, and divides into many branches, which are garniſhed with ſtiff leaves, placed alternately; they are about an inch and a half long, and a little more in breadth, indented at the top, with a ſtiff reflexed border, of a gray colour on their upper ſide, but of a ruſty iron colour on their under, ſtanding upon ſhort foot-ſtalks. The flowers come out ſingly along the ſide of the branches; they have five ſmall white petals, which end in acute points, and five ſlender ſtamina, which ſpread open, and are terminated by obtuſe ſummits. In the center is ſituated a roundiſh germen, ſupporting a long bifid ſtigma, which is permanent. The germen afterward turns to a round berry, with one or two cells, each having one oblong ſeed.

The firſt ſort is too tender to live abroad in England, but as it requires no artificial heat, ſo may be preſerved through the winter in a good green-houſe, where it deſerves a place for the beauty of its leaves, which are very thick, of a deep green, and differing in appearance from every other plant; this may be propagated by laying down thoſe ſhoots which are produced near the root, but they are long in putting out roots. The ſhoots ſhould be twiſted in the part which is laid, to facilitate their putting out roots; if theſe are laid down in the autumn, they will put out roots ſufficient to remove by the following autumn; it may alſo be propagated by cuttings, but this is a tedious method, as they are ſeldom rooted enough to tranſplant in leſs than two years. When this is practiſed, the young ſhoots of the former year ſhould be cut off, with a ſmall piece of the old wood at the bottom, in the ſpring, and planted in pots filled with loamy earth, and plunged into a moderate hot-bed, covering the pots with glaſſes, which ſhould be cloſe ſtopped down to exclude the external air; they ſhould be pretty well watered at the time they are planted, but afterward they will require but little wet; the glaſſes over them ſhould be covered every day with mats, to ſcreen the cuttings from the ſun during the heat of the day, but in the morning before the ſun is too warm, and in the afternoon, when the ſun is low, they ſhould be uncovered, that the oblique rays of the ſun may raiſe a gentle warmth under the glaſſes. With this care the cuttings will take root, but where it is wanting, they ſeldom ſucceed. When the cuttings or layers are rooted, they ſhould be each planted in a ſeparate ſmall pot, filled with ſoft loamy ſoil, and placed in the ſhade till they have taken new root; then they may be removed to a ſheltered ſituation, where they may remain during the ſummer ſeaſon; and, before the froſts of the autumn come on, they muſt be removed into the green-houſe, and treated in the ſame way as the other plants of that country, giving them but little water in cold weather, and in mild weather admitting the free air. In ſummer they muſt be removed into the open air, and placed in a ſheltered ſituation with other exotic plants, and in very warm weather they muſt be watered three times a week, but it muſt not be given them too freely at any time. When the plants have obtained ſtrength, they will produce flowers and fruit, which, in warm ſeaſons, will ripen perfectly; and if the ſeeds are ſown ſoon after they are ripe, in pots, and plunged into the tan-bed in the ſtove, the plants will come up the ſpring following, and may then be treated in the ſame manner as thoſe which are propagated by cuttings and layers.

The ſecond ſort is not altogether ſo hardy as the firſt, ſo muſt have a warmer place in the green-houſe in winter, and ſhould not be placed abroad quite ſo early in the ſpring, nor ſuffered to remain abroad ſo late in the autumn, but if the green-houſe is warm, the plants will require no additional heat. This may be propagated by layers and cuttings, in the ſame manner as the firſt, and requires the ſame care, for the cuttings are with difficulty made to root; nor will the branches which are laid, put out roots in leſs than a year, and if theſe are not young ſhoots, they will not take root.

As this ſort does not produce ſeeds in England, it can be only propagated by layers and cuttings, which being difficult to root, occaſions its being ſcarce at preſent in Europe.

The third ſort is yet more rare than either of the former, and is with greater difficulty propagated, for the layers and cuttings are commonly two years before they get roots ſufficient to remove, and as it never produces ſeeds here, it can be no other way propagated; this is alſo tenderer than either of the other ſorts, ſo requires a moderate degree of heat in winter, for without ſome artificial warmth, it will ſeldom live through the winters in England. In the middle of ſummer the plants may be placed abroad in a warm ſituation, but they muſt be removed into ſhelter early in the autumn, before the cold nights come on, otherwiſe they will receive a check, which they will not recover in winter; during the ſummer ſeaſon they ſhould be gently watered three times a week in dry weather, but in winter they will require to be ſeldom watered.

The fourth ſort is much more impatient of cold than either of the other, being a native of a warmer country. This is propagated by ſeeds, which muſt be procured from the country where it grows naturally, for it does not produce any here. Theſe do not grow the firſt year, ſo the ſeeds ſhould be ſown in pots filled with light earth, and plunged into a moderate hot-bed of tanners bark, where they may remain all the ſummer; and in the autumn they ſhould be removed into the bark-ſtove, and plunged into the tan-bed between the other pots of plants, in any vacant ſpaces; there they may remain till ſpring, when they ſhould be taken out of the ſtove, and plunged into a freſh hot bed, which will bring up the plants. When theſe are fit to remove, they ſhould be each tranſplanted into a ſeparate ſmall pot, filled with a ſoft loamy earth, and plunged into a hot-bed again, being careful to ſhade them from the ſun till they have taken new root, after which they muſt be treated in the ſame manner as other tender plants from the ſame country, always keeping them in the tan-bed; and in winter they muſt have a temperate warmth, otherwiſe they will not live here.

All the ſorts delight in a ſoft, gentle, loamy ſoil, not over ſtiff, ſo as to detain the wet; nor ſhould the ſoil be too light, for in ſuch they ſeldom thrive. They retain their leaves all the year, ſo make a good appearance in the winter ſeaſon, their leaves being remarkably ſtiff and of a fine green, eſpecially the firſt ſort, whoſe fruit ripens in winter, which when it is in plenty on the plants, affords an agreeable variety.

MAYS. See ZEA.

MEADIA. Cateſb. Carol. 3. p. 1. Dodecatheon. Lin. Gen. Plant. 183.

The CHARACTERS are,

It hath a ſmall involucrum of many leaves, in which are many flowers. The flower hath a permanent empalement of one leaf, cut into five long ſegments which are reflexed. The flower hath one petal, cut into five parts, whoſe tube is ſhorter than the empalement, and the limb is reflexed backward. It hath five ſhort obtuſe ſtamina ſitting in the tube, terminated by arrow-pointed ſtigmas, which are connected into a beak, with a conical germen, ſupporting a ſlender ſtyle longer than the ſtamina, crowned by an obtuſe ſtigma. The empalement afterward becomes an oblong oval capſule with one cell, opening at the top, and filled with ſmall ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, which includes thoſe plants whoſe flowers have five ſtamina and one ſtyle. The title of this genus was given to it by Mr. Mark Cateſby, F. R. S. in honour of the late Dr. Mead, who was a generous encourager of every uſeful branch of ſcience; but being himſelf no great botaniſt, Dr. Linnæus was unwilling any plant ſhould bear his name, ſo he has altered it to that of Dodecatheon, which was a title applied by Pliny to a ſpecies of Primroſe with a yellow root, and leaves like the Garden Lettuce.

We have but one SPECIES of this genus, viz.

MEADIA (*Dodecatheon.*) Cateb. Hiſt. Carol. App. 1. tab. 1. *Meadia.* Auricula urſi Virginiana, floribus boraginis, inſtar roſtratis, cyclaminum more reflexis. Pluk. Alm. 62. tab. 79. fol. 6. *Bear's-ear of Virgina, whoſe flower has a beak like that of Borage, and reflexed petals like thoſe of Sowbread.*

This plant grows naturally in Virginia, and other parts of North America, from whence it was ſent by Mr. Baniſter, many years ſince, to Dr. Compton, Lord Biſhop of London, in whoſe curious garden I firſt ſaw this plant growing in the year 1709; after which the plant was for ſeveral years loſt in England, till within a few years paſt, when it was again obtained from America, and has been propagated in pretty great plenty. It hath a yellow perennial root, from which comes out ſeveral long ſmooth leaves in the ſpring, which are near ſix inches long, and two and a half broad; at firſt ſtanding erect, but afterward they ſpread on the ground, eſpecially if the plants are much expoſed to the ſun; from between theſe leaves ariſe two, three, or four flower-ſtalks, in proportion to the ſtrength of the roots, which riſe eight or nine inches high, they are ſmooth, naked, and are terminated by an umbel of flowers, under which is ſituated the many-leaved involucrum. Each flower is ſuſtained by a pretty long ſlender foot-ſtalk which is recurved, ſo that the flower hangs downward. The flower has but one petal, which is deeply cut into five ſpear-ſhaped ſegments, which are reflexed upward like the flowers of Cyclamen or Sowbread; the ſtamina, which are five in number, are ſhort, and ſit in the tube of the flower, having five arrow-pointed ſummits, which are connected together round the ſtyle, forming a ſort of beak. The flowers are purple, inclining to a Peach bloſſom colour, and have an oblong germen ſituated in the bottom of the tube, which afterward becomes an oval capſule incloſed by the empalement, with the permanent ſtyle on its apex, which, when ripe, opens at the top to let out the ſeeds, which are faſtened round the ſtyle. This plant flowers the beginning of May, and the ſeeds ripen in July, ſoon after which the ſtalks and leaves decay, ſo that the roots remain inactive till the following ſpring.

This plant is propagated by offsets, which the roots put out pretty freely when they are in a looſe moiſt ſoil and a ſhady ſituation; the beſt time to remove the roots, and take away the offsets, is in Auguſt, after the leaves and ſtalks are decayed, that they may be fixed well in their new ſituation before the froſt comes on. It may alſo be propagated by ſeeds, which the plants generally produce in plenty; theſe ſhould be ſown in the autumn ſoon after they are ripe, either in a ſhady moiſt border, or in pots, which ſhould be placed in the ſhade; in the ſpring the plants will come up, and muſt then be kept clean from weeds, and if the ſeaſon proves dry, they muſt be frequently refreſhed with water; nor ſhould they be expoſed to the ſun, for while the plants are young, they are very impatient of heat, ſo that I have known great numbers of them deſtroyed in two or three days, which were growing to the full ſun. Theſe young plants ſhould not be tranſplanted till their leaves are decayed, then they may be carefully taken up and planted in a ſhady border, where the ſoil is looſe and moiſt, at about eight inches diſtance from each other, which will be room enough for them to grow one year, by which time they will be ſtrong enough to produce flowers, ſo may then be tranſplanted into ſome ſhady borders in the flower-garden, where they will appear very ornamental during the continuance of their flowers.

At the firſt many ſuppoſed this plant to be tender, ſo planted it in warm ſituations and nurſed it too much, whereby the plants were often killed; but by experience it is found to be ſo hardy, as not to be hurt by the ſevereſt cold of this country; but it will not thrive in a very dry ſoil, or where it is greatly expoſed to the ſun.

MEADOW.

Under the general title of Meadow, is commonly comprehended all paſture land, or at leaſt all Graſs land, which is mown for hay; but I chuſe rather to diſtinguiſh ſuch land only by this appellation, which is ſo low, as to be too moiſt for cattle to graze upon them in winter, being generally too wet to admit heavy cattle, without poaching and ſpoiling the ſward; and thoſe Graſs lands which are drier, I ſhall diſtinguiſh by the title of paſture.

There are two ſorts of Meadows in England, one of which is ſtiled Water Meadows, and the other are ſimply called Meadows.

Water Meadows are thoſe which lie contiguous to rivers or brooks, from whence the water can be carried to overflow the Graſs at pleaſure. Of theſe there are large tracts in ſeveral parts of England, which, if ſkilfully managed, would become much more profitable to their owners than they are at preſent, as hath been already mentioned in another place; for nothing can be more abſurd than the common practice of flowing theſe low grounds all the winter, whereby the roots of all the ſweeteſt kinds of Graſs are deſtroyed, and only ſuch Graſſes left as are natives of marſhes, which are coarſe and ſour: and if people were curious to examine the herbage of theſe Water Meadows, they would find the bulk of them compoſed of bad weeds, ſuch as grow by the ſides of rivers, brooks, and ditches, of which the ſeveral ſorts of Docks make no ſmall ſhare; and although many of theſe Meadows produce a great burden of what the country people call hay, yet this is only fit for cows, cart-horſes, and other animals, which by hard labour and hunger, are driven to eat it; for horſes which have been accuſtomed to feed on good hay, will ſtarve before they will touch it: and after the Graſs is mown off theſe Meadows, and cattle turned in to graze upon them, how common is it to ſee the land almoſt covered with theſe rank weeds, which the cattle never will eat! Which muſt always be the condition of ſuch Meadows, where the water is let over them in autumn and winter; for, as the ſides of rivers and brooks do every where abound with theſe rank weeds, whoſe ſeeds ripen in autumn, and falling into the water, they are carried by the ſtream, and depoſited on the flowed land, where they grow and fill the ground in every part; but ſo incurious are the generality of farmers in this reſpect, that if the ground is but well covered, they care not what it is, few of them ever taking any pains to weed or clean their paſtures.

The method which I propoſe for the management of theſe Meadows is, never to flow them till the middle or latter end of March, excepting once or twice in winter, when there may happen floods, which may bring down a great ſhare of ſoil from the upper lands, at which times it will be of great ſervice to let water upon the Meadows, that the ſoil may ſettle there; but the ſooner the wet is drained off when this is lodged, the greater advantage the Meadows will receive by it; but from the end of March to the middle of May, in dry ſeaſons, by frequently letting on the water, the growth of the Graſs will be greatly encouraged, and at this ſeaſon there will be no danger of deſtroying the roots of the Graſs; and after the hay is carried off the ground, if the ſeaſon ſhould prove dry, it will be of great ſervice to the Graſs, if the Meadows are flowed again; but when this is practiſed, no cattle ſhould be turned into the Meadows, till the ſurface of the ground is become firm enough to bear their weight without poaching the land, for otherwiſe the Graſs will ſuffer more from the treading of the cattle, than it will receive benefit by the flowing; but theſe are things which the country people ſeldom regard, ſo that the Meadows are generally very unſightly, and rendered leſs profitable.

I would alſo recommend the weeding of theſe Meadows twice a year; the firſt time in April, and again in October; at which times if the roots of Docks and all bad weeds are cut up with a ſpaddle, the Meadows will ſoon be cleared of this trumpery, and the herbage greatly improved.

Another great improvement of theſe lands might be procured, by rolling them with a heavy roller in ſpring and autumn. This will preſs the ſurface of the ground even, whereby it may be mown much cloſer, and it will alſo ſweeten the Graſs; and this piece of huſbandry is of more ſervice to paſtures than moſt people are aware of.

As to thoſe Meadows which cannot be flowed, there ſhould be the ſame care taken to weed and roll them, as hath been directed for the Water Meadows; as alſo never to let heavy cattle graze upon them in winter when they are wet; for the cattle will then poach them, and greatly injure the Graſs; therefore theſe ſhould be fed down as cloſe as poſſible in the autumn, before the heavy rains fall to render the ground ſoft; and thoſe paſtures which are drier, may be kept to ſupply the want of theſe in winter; and where there are not cattle enough to eat down the Graſs in time, it will be much better to cut off what is left, than to ſuffer it to rot upon the ground, for that will prevent the Graſs from ſhooting early in the ſpring; but where people have not cattle enough of their own to eat down the Graſs in time, they had much better take in ſome of their neighbours, than ſuffer their fog (as it is called) to remain all the winter. When theſe Meadows are fed in the autumn, the greater variety of animals are turned in, the cloſer they will eat the Graſs; and I am fully convinced, the cloſer it is eaten, the better the Graſs will come up the following ſpring; therefore, if during the time while the cattle are feeding, the Meadows are well rolled, the animals will eat the Graſs much cloſer than they otherwiſe would.

Thoſe perſons who are beſt ſkilled in this part of huſbandry, always dreſs their Meadows every other, or at leaſt every third year, without which it is in vain to expect any good crop of hay; but the generality of the farmers are ſo much diſtreſſed for dreſſing to ſupply their Corn land, as not to have any to ſpare for their Meadows, ſo that they are content with what the land will naturally produce, rather than take any part of their manure from their arable ground; but this is a very imprudent piece of huſbandry; for if land is to be annually mowed far hay, can it be ſuppoſed that it will produce a good crop long, unleſs there are proper dreſſings allowed it? And when ground is once beggared for want of manure, it will be ſome years before it can be recovered again; but I ſhall reſerve what is neceſſary to be farther enlarged on this ſubject, to be fully treated under the article of PASTURE.

MEADOW SAFFRON. See COLCHICUM.

MEDEOLA. Lin. Gen. Plant. 411.

The CHARACTERS are,

The flower has no empalement; it hath ſix oblong oval petals which are equal, ſpread open, and turn backward; and ſix awl-ſhaped ſtamina the length of the petal, terminated by incumbent ſummits, and three corniculated germen terminating the ſtyle, crowned by thick recurved ſtigmas. The germen afterward turns to a roundiſh trifid berry with three cells, each containing one heart-ſhaped ſeed.

This genus of plants is ranged in the third ſection of Linnæus's ſixth claſs, which includes thoſe plants whoſe flowers have ſix ſtamina and three ſtyles.

The SPECIES are,

1. MEDEOLA (*Aſparagoides*) foliis ovato-lanceolatis alternis, caule ſcandente. *Medeola with oval, ſpear-ſhaped, alternate leaves, and a climbing ſtalk.* Aſparagus Africanus, ſcandens, myrti folio. Hort. Piſſ. 17. *Climbing African Aſparagus, with a Myrtle leaf.*
2. MEDEOLA (*Anguſtifolia*) foliis lanceolatis alternis, caule ſcandente. *Medeola with ſpear-ſhaped alternate leaves, and a climbing ſtalk.* Aſparagus Africanus, ſcandens, myrti folio anguſtiore. Hort. Piſſ. 17. *Climbing African Aſparagus, with a narrower Myrtle leaf.*
3. MEDEOLA (*Virginiana*) foliis verticillatis, ramis inermibus. Lin. Sp. Plant. 339. *Medeola with leaves growing in whorls and ſmooth branches.* Lilium ſive martagon puſillum, floribus minutiſſimè herbaceis. Pluk. Alm. 410. tab. 328. fol. 4. *The Lily or little Martagon, with very ſmall herbaceous flowers.*

The firſt ſort grows naturally at the Cape of Good Hope; this hath a root compoſed of ſeveral dugs or oblong knobs, which unite together at the top like that of the Ranunculus, from which ariſe two or three ſtiff winding ſtalks, which divide into branches riſing four or five feet high, if they meet with any neighbouring ſupport to which they can faſten, otherwiſe they will fall to the ground; theſe are garniſhed with oval ſpear-ſhaped leaves, ending in acute points, placed alternately, and ſitting cloſe to the ſtalks; they are of a light green on their under ſide, and dark on their upper. The flowers come out from the ſide of the ſtalks, ſometimes ſingly, and at others there are two upon a ſlender ſhort foot-ſtalk; they have ſix oblong equal petals which ſpread open, and are of a dull white colour; within theſe are ranged ſix ſtamina, which are as long as the petals, terminated by incumbent ſummits. In the center is ſituated a germen with three horns, upon a ſhort ſtyle, crowned by three thick recurved ſtigmas; the germen afterward turns to a roundiſh berry with three cells, each containing one heart-ſhaped ſeed. It flowers the beginning of winter, and the ſeeds are ripe in the ſpring.

The ſecond ſort is alſo a native of the Cape of Good Hope, from whence I received the ſeeds. This hath a root like the firſt, but the ſtalks are not ſo ſtrong; they climb higher, but do not branch ſo much; the leaves are much longer and narrower, and are of a grayiſh colour. The flowers come from the ſide of the branches, two or three upon each foot-ſtalk; they are of an herbaceous white colour, ſhaped like thoſe of the former ſort, and appear about the ſame time, but this has not produced any fruit here. Theſe are undoubtedly diſtinct ſpecies, for they never vary when they are propagated by ſeeds.

Both theſe ſorts propagate freely by offsets from the roots, ſo that when they are once obtained, there will be no neceſſity of ſowing their ſeeds, which commonly lie a year in the ground, and the plants will not be ſtrong enough to flower in leſs than two years more, whereas the offsets will flower the following ſeaſon. The time for tranſplanting and parting of the roots is in July, when their ſtalks are entirely decayed, for they begin to ſhoot toward the end of Auguſt, and keep growing all the winter, and decay in the ſpring. Theſe roots ſhould be planted in pots filled with good kitchen-garden earth, and may remain in the open air till there is danger of froſt, when they muſt be removed into ſhelter, for they are too tender to live through the winter in the open air; but if they are placed in a warm green-houſe, they will thrive and flower very well, but they do not produce fruit unleſs they have ſome heat in winter; therefore where that is deſired, the plants ſhould be placed in a ſtove kept to a moderate degree of warmth. During the winter, when the plants are in vigour, they ſhould be frequently, but gently watered; but when the ſtalks begin to decay, they muſt have very little wet, for much moiſture will rot them while they are in an inactive ſtate; during which time, if the pots are placed where they have only the morning ſun, they will require little or no water: but when they begin to ſhoot out their ſtalks, they ſhould be removed to a warmer ſituation, and ſhould then be frequently but gently watered.

The flowers of theſe plants make no great appearance, ſo the plants are not preſerved for their beauty; but as their ſtalks are climbing, and their leaves are in full vigour in winter, during that ſeaſon they add to the variety in the green-houſe.

The third ſort is a native of North America; it is by Dr. Linnæus joined to this genus, in which I have followed him; though, if I remember rightly, the characters of this ſort do not exactly agree with thoſe of the other, for the flower is either polypetalous, or is cut into many ſegments, and has but five ſtamina; it being ſome years ſince I ſaw the flowers, I cannot be very certain if I am right. This hath a ſmall ſcaly root, from which ariſes a ſingle ſtalk about eight inches high, garniſhed with one whorl of leaves at a ſmall diſtance from the ground, and at the top there are two leaves ſtanding oppoſite; between theſe come out three ſlender foot-ſtalks which turn downward, each ſuſtaining one pale herbaceous flower with a purple pointal. It flowers in June, but I have not ſeen any fruit upon it.

This plant is hardy enough to live in the open air, but does not propagate faſt here, as it produces no ſeeds, ſo can only be encreaſed by offsets.

MEDICA. Tourn. Inſt. R. H. 410. tab. 231. Medicago. Tourn. Inſt. 412. Lin. Gen. Plant. 805. [This plant takes its name from Media (as Pliny writes) becauſe when Darius Hyſtaſpis carried his army into Greece, he had with him a great many ſacks of this ſeed for provender for his cattle, and ſo the ſeeds came to be ſcattered in Greece.] Medick, or La Lucerne.

The CHARACTERS are,

The flower hath a bell-ſhaped empalement of one leaf, cut into five equal acute points. The flower is of the butterfly kind; the ſtandard is oval, entire, and the border is reflexed; the two wings are oblong, oval, and fixed by an appendix to the keel; the keel is oblong, bifid, obtuſe, and reflexed toward the ſtandard. It has ten ſtamina, nine of which are joined almoſt to their tops, the other is ſingle; they are terminated by ſmall ſummits. It hath an oblong compreſſed germen which is incurved, ſitting on a ſhort ſtyle, terminated by a ſmall ſtigma; this and the ſtamina are involved by the keel and ſtandard. The germen afterward turns to a compreſſed moon-ſhaped pod, incloſing ſeveral kidney-ſhaped ſeeds.

This genus of plants is ranged in the third ſection of Linnæus's ſeventeenth claſs, which includes the herbs with a butterfly flower, having ten ſtamina in two houſes. He alſo has joined the Medica and

Medicago of Tournefort together, making them one genus under the title Medicago, but Tournefort makes the diſtinguiſhing character of Medicago to conſiſt in having a falcated compreſſed pod. Therefore I ſhall here ſeparate thoſe plants whoſe pods are of that form, from the others whoſe pods are twiſted like a ſcrew; and as the title of Medica was firſt applied to the Lucern, ſo I ſhall continue it to thoſe ſpecies as have ſuch pods, and refer the others to the genus of Medicago.

The Species are,

1. Medica (*Sativa*) pedunculis racemoſis, leguminibus contortis, caule erecto glabro. Lin. Sp. 1096. *Medick with branching foot-ſtalks, contorted pods, and an erect ſmooth ſtalk.* Medica major, erectior, floribus purpuraſcentibus. J. B. 2. 382. *Greater upright Medick with purpliſh flowers, commonly called La Lucerne, and by the French, Burgundy Hay.*
2. Medica (*Falcata*) pedunculis racemoſis, leguminibus lunatis, caule proſtrato. Flor. Suec. 620. *Medick with branching foot-ſtalks, moon-ſhaped pods, and trailing ſtalks.* Medica ſylveſtris, floribus croceis. J. B. 2. 383. *Wild Medick with Saffron-coloured flowers.*
3. Medica (*Radiata*) leguminibus reniformibus, margine dentatis, foliis ternatis. Hort. Cliff. 377. *Medick with kidney-ſhaped pods indented on the borders, and trifoliate leaves.* Medicago annua, trifolii facie. Tourn. Inſt. R. H.. 412. *Annual Medicago with the appearance of Trefoil.*
4. Medica (*Hiſpanica*) caule herbaceo procumbente, foliis pinnatis, leguminibus ciliato-dentatis. *Medick with a trailing herbaceous ſtalk, winged leaves, and pods having hairy indentures.* Medicago vulnerariæ facie Hiſpanica. Tourn. Inſt. R. H. 412. *Spaniſh Medicago with the appearance of Ladies Finger.*
5. Medica (*Italica*) caule herbaceo proſtrato, foliis ternatis, foliolis cuneiformibus ſupernè ſerratis, leguminibus margine integerrimis. *Medick with a proſtrate herbaceous ſtalk, trifoliate leaves whoſe lobes are wedge-ſhaped and ſawed at the top, and the borders of the pods entire.* Medicago Italica, annua maritima, trifolia, polycarpos, fructu toroſo non ſpinoſo. Mitchel. Hort. Piſſ. *Annual, Italian, maritime Medicago with trifoliate leaves, and bearing much fruit, which is thick and without ſpines.*
6. Medica (*Cretica*) caule herbaceo proſtrato, foliis radicalibus integerrimis, caulinis pinnatis leguminibus dentatis. *Medick with a proſtrate herbaceous ſtalk, the bottom leaves entire, thoſe on the ſtalks winged, and indented pods.* Medicago vulnerariæ facie Cretica. Tourn. Inſt. 412. *Cretan Medicago, with the appearance of Ladies Finger.*
7. Medica (*Arborea*) leguminibus lunatis margine integerrimis caule arboreo. Hort. Cliff. 376. *Medick with moon-ſhaped pods whoſe borders are entire, and a tree-like ſtalk.* Medicago trifolia, fruteſcens, incana. Tourn. Inſt. R. H. 412. *Shrubby, hoary, three-leaved Medica, or the Cytiſus Virgilii.*

The firſt ſort hath a perennial root and annual ſtalks, which riſes near three feet high in good land; theſe are garniſhed with trifoliate leaves at each joint, whoſe lobes are ſpear-ſhaped, about an inch and a half long, and half an inch broad, a little ſawed toward their top, of a deep green, and placed alternately on the ſtalks. The flowers grow in ſpikes, which are from two to near three inches in length, ſtanding upon naked foot-ſtalks which are two inches long, riſing from the wings of the ſtalk; they are of a Pea bloom or butterfly kind, of a fine purple colour, and are ſucceeded by compreſſed moon-ſhaped pods, which contain ſeveral kidney-ſhaped ſeeds. It flowers in June, and the ſeeds ripen in September.

There are the following varieties of this plant:
One with Violet-coloured flowers.
Another with pale blue flowers.
And a third with variegated flowers.

Theſe variations of their flowers have accidentally riſen from ſeed, therefore are not to be ſuppoſed different plants; yet thoſe with the pale blue and variegated flowers are never ſo ſtrong as thoſe with purple, ſo are leſs profitable to the cultivators.

This plant is ſuppoſed to have been brought originally from Media, and from thence had its name Medica: it is by the Spaniards called Alfaſa; by the French, La Lucerne, and Grand Trefle; and by ſeveral botanic writers it is called Fœnum Burgundiacum, i. e. Burgundian Hay. But there is little room to doubt of this being the Medica of Virgil, Columella, Palladius, and other ancient writers of huſbandry, who have not been wanting to extol the goodneſs of this fodder, and have given direction for the cultivation of it in thoſe countries where they lived.

But notwithſtanding it was ſo much commended by the antients, and hath been cultivated to ſo good purpoſe by our neighbours in France and Switzerland for many years, it hath not as yet found ſo good reception in our country as could be wiſhed; nor is it cultivated in conſiderable quantities, though it is evident, it will ſucceed as well in England as in either of the before-mentioned countries, though will not bear cutting ſo often here, yet is extremely hardy, and reſiſts the ſevereſt cold of our climate: as a proof of this, I muſt beg leave to mention, that the ſeeds which have have happened to be ſcattered upon the ground in autumn, have come up, and the plants have endured the cold of a ſevere winter, and made very ſtrong plants the following ſeaſon.

About the year 1650, the ſeeds of this plant were brought over from France, and ſown in England; but whether for want of ſkill in its culture, whereby it did not ſucceed, or that the people were ſo fond of going on in their old beaten road, as not to try the experiment whether it would ſucceed here or not, was the occaſion of its being entirely neglected in England, I cannot ſay, but it is very certain that it was neglected many years, ſo as to be almoſt forgotten. However, I hope, before I quit this article, to give ſuch directions for its culture, as will encourage the people of England to make farther trial of this valuable plant, which grows in the greateſt heat, and alſo in very cold countries, with this difference only, that in very hot countries, ſuch as the Spaniſh Weſt-Indies, &c. where it is the chief fodder for their cattle at this time, they cut it every week; whereas in cold countires, it is ſeldom cut oftener than four or five times in a year. And it is very likely that this plant may be of great ſervice to the inhabitants of Barbadoes, Jamaica, and the other hot iſlands in the Weſt-Indies, where one of the greateſt things they want is fodder for their cattle; ſince by the account given of this plant by Pere Feuillé, it thrives exceedingly in the Spaniſh Weſt-Indies, particularly about Lima, where they cut it every week, and bring it into the market to ſell, and is there the only fodder cultivated.

It is alſo very common in Languedoc, Provence, aad Dauphiné, and all over the banks of the Rhone, where it produces abundantly, and may be mowed five or ſix times in a year. Horſes, mules, oxen, and other domeſtic cattle, love it exceedingly; but above all when it is green, if they are permitted to feed on it, and eſpecially the black cattle, which will feed very kindly upon the dried plant; the exceſs of which is, by many people, thought to be very dangerous; but it is ſaid to be exceeding good for milch cattle, to promote their quantity of milk; and is alſo ſaid to agree with horſes the beſt of all, though ſheep, goats, and moſt other cattle, will feed upon it, eſpecially when young.

The directions given by all thoſe who have written of this plant are very imperfect, and generally ſuch as, if practiſed in this country, will be found entirely wrong; for many of them order the mixing of this ſeed with Oats or Barley, (as is practiſed for Clover) but in this way it ſeldom comes up well, and if it does, it will draw up ſo weak by growing amongſt the Corn, as not to be recovered under a whole year, if ever it can be brought to its uſual ſtrength again. Others have directed it to be ſown upon a low, rich, moiſt ſoil, which is found to be the worſt next to a clay, of any for this plant; in both which the roots will rot in winter, and in a year or two the whole crop will be deſtroyed.

But the ſoil in which this plant is found to ſucceed beſt in this country is, a light, dry, looſe, ſandy land, which ſhould be well ploughed and dreſſed, and the roots of all noxious weeds, ſuch as Couch Graſs, &c. deſtroyed, otherwiſe they will overgrow the plants while young, and prevent their progreſs.

The beſt time to ſow the ſeed is about the middle of April, when the weather is ſettled and fair; for if you ſow it when the ground is very wet, or in a rainy ſeaſon, the ſeeds will burſt and come to little (as is often the caſe with ſeveral ſorts of the leguminous plants;) therefore you ſhould always obſerve to ſow it in a dry ſeaſon, and if there happens rain in about a week or ten days after it is ſown, the plants will ſoon appear above ground.

But the method I would direct for the ſowing theſe ſeeds is as follows: after having well ploughed and harrowed the land very fine, you ſhould make a drill quite acroſs the ground, about half an inch deep, into which the ſeeds ſhould be ſcattered very thin by a hopper fixed to a drill plough; then cover them over half an inch thick, with the earth that came out of the drill; then proceed to make another drill about two feet and a half from the former, ſowing the ſeeds therein in the ſame manner as before, and ſo proceed through the whole ſpot of ground, allowing the ſame diſtance between row and row, and ſcatter the ſeeds very thin in the drills. In this manner, an acre of land will require about ſix pounds of ſeeds; for when it is ſown thicker, if the ſeed grows well, the plants will be ſo cloſe as to ſpoil each other in a year or two, the heads of them growing to a conſiderable ſize, as will alſo the roots, provided they have room. I have meaſured the crown of one root, which was in my poſſeſſion, eighteen inches diameter; from which I cut near four hundred ſhoots at one time, which is an extraordinary increaſe, and this upon a poor, dry, gravelly ſoil, which had not been dunged for many years, but the root was at leaſt fourteen years old; ſo that if this crop be well cultivated, it will continue many years, and be equally good as when it was firſt ſown; for the roots generally run down very deep in the ground, provided the ſoil be dry; and although they ſhould meet a hard gravel a foot below the ſurface, yet their roots would penetrate it, and make their way downward, as I have experienced, having taken up ſome of them which were above four feet in length, and had run above two feet into a rock of gravel, which was ſo hard as not to be looſened without mattocks and crows of iron, and that with much difficulty.

The reaſon for directing this ſeed to be ſown in rows is, that the plants may have room to grow; and for the better ſtirring the ground between them, to deſtroy the weeds, and encourage the growth of the plants, which may be very eaſily effected with a Dutch hoe, juſt after the cutting the crop each time, which will cauſe the plants to ſhoot again in a very little time, and be much ſtronger than in ſuch places where the ground cannot be ſtirred; but when the plants firſt come up, the ground between them ſhould be hoed by hand with a common hoe; and if in doing of this you cut up the plants where they are too cloſe in the rows, it will cauſe the remaining to be much ſtronger. This hoeing ſhould be repeated two or three times while the plants are young, according as the weeds are produced, obſerving always to do it in dry weather, that the weeds may the better be deſtroyed; for if it be done in moiſt weather, they will take root and grow again.

With this management, the plants will grow to the height of two feet, or more, by the beginning of Auguſt, when the flowers will begin to appear, when it ſhould be cut for the firſt time, obſerving to do it in a dry ſeaſon, eſpecially if it is to be made into hay, and keep it often turned, that it may ſoon dry, and be carried off the ground; for if it lie long upon the roots, it will prevent their ſhooting again. After the crop is taken off, you ſhould ſtir the ground between the rows with a hoe, to kill the weeds, and looſen the ſurface, which will cauſe the plants to ſhoot again in a ſhort time, ſo that by the middle of September there will be ſhoots four or five inches high, when you may turn in ſheep upon it to feed it down, for it will not be fit to cut again the ſame ſeaſon; nor ſhould the ſhoots be ſuffered to remain upon the plants, which would decay when the froſty weather comes on, and fall down upon the roots, and prevent their ſhooting early the ſucceeding ſpring; but theſe ſheep ſhould not remain ſo long upon it as to endanger the crowns of the roots.

So that the beſt way is to feed it until November, when it will have done ſhooting for that ſeaſon; but it ſhould not be fed by large cattle the firſt year, becauſe the roots being young, would be in danger of being deſtroyed, either by their trampling upon them, or their pulling them out of the ground; but ſheep will be of ſervice to the roots by dunging the ground, provided they do not eat it too cloſe.

The beginning of February, the ground between the roots ſhould be again ſtirred with the hoe, to encourage them to ſhoot again; but in doing of this you ſhould be careful not to injure the crown of the roots, upon which the buds are at that time very turgid, and ready to puſh. With this management, if the ſoil be warm, by the middle of March the ſhoots will be five or ſix inches high, when, if you are in want of fodder, you may feed it down till a week in April; after which it ſhould be ſuffered to grow for a crop, which will be fit to cut the beginning of June, when you ſhould obſerve to get it off the ground as ſoon as poſſible, and ſtir the ground again with a Dutch hoe, which will forward the plants ſhooting again, ſo that by the middle of July, there will be another crop fit to cut, which muſt be managed as before: after which it ſhould be fed down again in autumn; and as the roots by this time will have taken deep hold in the ground, there will be little danger of hurting them, if you ſhould turn in larger cattle; but you muſt always obſerve not to ſuffer them to remain after the roots have done ſhooting, leſt they ſhould eat down the crown of the roots below the buds, which would conſideraby damage, if not deſtroy them. In this manner you may continue conſtantly to have two crops to cut, and two feedings upon this plant, and in good ſummers there may be three crops cut, and two feedings; which will be a great improvement, eſpecially as this plant will grow upon dry barren ſoils, where Graſs will produce little, eſpecially in dry ſeaſons, when it will be of great uſe, the Graſs being often burnt up. And as it is an early plant in the ſpring, ſo it will be of great ſervice when fodder falls ſhort at that ſeaſon, when it will be fit to feed at leaſt a month before Graſs or Clover; for I have had this plant eight inches high by the tenth of March, old ſtyle, at which time the Graſs in the ſame place has ſcarcely been one inch high.

That the cold will not injure this plant, I am fully ſatisfied; for in the very cold winter, anno 1729-30, I had ſome roots of this plant which were dug up in October, and laid upon the ground in the open air till the beginning of March, when I planted them again, and they ſhot out very vigorouſly ſoon after; nay, even while they lay upon the ground, they ſtruck out fibres from the under ſide of the roots, and begun to make ſhoots from the crown of the roots. But that wet will deſtroy the roots I am fully convinced, for I ſowed above an acre upon a moiſt ſpot of ground for a trial, which came up very well, and flouriſhed exceedingly during the ſummer ſeaſon, but in winter, when the great rains fell, the roots began to rot at bottom, and before the ſpring moſt of them were deſtroyed. There has been lately ſome perſons who have adviſed the ſowing of Lucern in broad-caſt, and to make uſe of a ſtrong harrow, to tear up and deſtroy the weeds which naturally grow up among the plants; but this advice has been given too prematurely, therefore it is to be hoped will not be followed by any diſcreet perſons, who are deſired to take a ſurvey of ſome of theſe lands which have been ſo cultivated three or four years, which I am fully perſuaded will convince them of the bad huſbandry, for no perſon who has any regard to neatneſs and utility, will ever practiſe this method.

The beſt places to procure the ſeed from, are Switzerland, and the northern parts of France, for the ſeeds ſaved in thoſe countries ſucceed better with us than that which comes from a more ſouthern climate; but this ſeed may be ſaved full as well in England, and in as great plenty, were people curious enough to let the firſt crop ſtand for that purpoſe; in order to which, a ſmall quantity of the plants ſhould be ſuffered to grow uncut till the ſeeds are ripe, which is commonly about the beginning of September, when it muſt be cut, and laid to dry in an open barn, where the air may freely paſs through, but be defended from the wet; for if it be expoſed thereto, it will ſhoot while it remains in the pod, whereby it will be ſpoiled. When it is quite dry, it muſt be threſhed out, and cleanſed from the huſk, and preſeved in a dry place till the ſeaſon for ſowing it; and this ſeed ſaved in England is much preferable to any brought from abroad, as I have ſeveral times experienced, the plants produced from it having been much ſtronger than thoſe produced from French, Helvetian, and Turkey ſeeds, which were ſown at the ſame time, and on the ſame ſoil and ſituation.

I am inclinable to think, that the reaſon of this plant not ſucceeding, when it has been ſown in England, has either been occaſioned by the ſowing it with Corn, with which it will by no means thrive (for though the plant be very hardy when grown pretty large, yet at its firſt coming up, if it be incommoded by any other plants or weeds, it ſeldom does well; therefore it ſhould always be ſown by itſelf, and carefully cleared from weeds until it has ſtrength, after which it is not eaſily deſtroyed;) or, perhaps, people have ſown it at a wrong ſeaſon, or in wet weather, whereby the ſeeds have rotted, and never come up, which hath diſcouraged their attempting it again: but however the ſucceſs has been, I dare aver, that if the method of ſowing and managing of this plant, which is here laid down, be duly followed, it will be found to thrive as well as any other ſort of plant now cultivated in England, producing a much greater crop than any other ſort of fodder, and will continue much longer; for if the ground be duly ſtirred after the cutting each crop, and the laſt crop fed as hath been directed, the plants will continue in vigour forty years or more, without renewing, provided they are not permitted to ſeed, which will weaken the roots more than four times cutting it would do. The hay of this plant ſhould be kept in cloſe barns, it being too tender to be kept in ricks open to the air as other hay; but it will remain good, if well dried before it be carried in, three years. The people abroad reckon an acre of this fodder ſufficient to keep three horſes all the year round.

And I have been aſſured by perſons of undoubted credit, who have cultivated this plant in England, that three acres of it have fed ten cart-horſes from the end of April to the beginning of October, without any other food, though they have been conſtantly worked. Indeed, the beſt uſe which can be made of this Graſs is, to cut it, and give it green to the cattle; where this hath been daily practiſed, I have obſerved that by the time the field has been cut over, that part which was the firſt cut hath been ready to cut again; ſo that there has been a conſtant ſupply in the ſame field, from the middle of April to the end of October: when the ſeaſon has continued long mild, and when the ſummers have proved ſhowery, I have known ſix crops cut in one ſeaſon, but in the drieſt ſeaſons there will be always three or four. When the plant begins to flower, it ſhould then be cut; for if it ſtands longer, the ſtalks will grow hard, and the under leaves will decay, ſo that the cattle will not ſo greedily devour it. Where there is a quantity of this cultivated, ſome of it ſhould be cut before the flowers appear, otherwiſe there will be too much to cut within a proper time.

When this is made into hay, it will require a great deal of making; for as the ſtalks are very ſucculent, it muſt be often turned, and expoſed a fortnight or longer, before it will be fit to houſe; for this requires a longer time to make than Saint Foin; therefore, when it is cut, it ſhould be carried to make upon ſome Graſs ground, becauſe the earth in the intervals of the rows will waſh up, and mix with the hay in every ſhower of rain, and by carrying it off as ſoon as it is cut, the plants will ſhoot up again ſoon; but it is not ſo profitable for hay, as to cut green for all ſorts of cattle, but eſpecially horſes, which are extremely fond of it; and to them it will anſwer the purpoſe both of hay and Corn, and they may be worked at the ſame time juſt as much as when they are fed with Corn, or dry food.

The ſecond ſort grows naturally in the ſouth of France, in Spain, Italy, and alſo in ſome more northern countries, and has been ſuppoſed only a variety of the firſt, but I have frequently cultivated this by ſeeds, and have never obſerved it to alter. The ſtalks of this are ſmaller, and never riſe ſo high, generally proſtrating on the ground; the leaves are not half ſo broad, the flowers are produced in ſhort roundiſh ſpikes, and are of a Saffron colour. This flowers about the ſame time as the firſt, and the ſeeds ripen the latter part of ſummer. It may be eaſily propagated by ſeeds, and hath a perennial root which will continue many years, but is ſeldom cultivated any where.

The third ſort grows naturally in Italy; this is an annual plant, having ſeveral ſlender branching ſtalks a foot and a half long, which ſpread on the ground, garniſhed with trifoliate leaves, whoſe lobes are oval, ſpear-ſhaped, and entire. The flowers are produced ſingly upon ſlender foot-ſtalks, which proceed from the ſide of the branches; they are ſmall, of a yellow colour, and ſhaped like thoſe of the former ſort; theſe are ſucceeded by broad, flat, moon-ſhaped pods, whoſe borders are indented, and theſe indentures are terminated by fine hairs; in each of theſe pods is lodged four or five kidney-ſhaped ſeeds. It flowers in June and July, and the ſeeds ripen in the autumn.

The fourth ſort grows naturally in Spain; this is alſo an annual plant, whoſe ſtalks grow a foot and a half long, trailing on the ground, and are garniſhed with winged leaves compoſed of two pair of ſmall lobes, terminated by one large, oval, ſpear-ſhaped lobe, which are a little hoary, and placed alternately at the joints. The flowers ſtand upon long ſlender foot-ſtalks, each ſuſtaining four or five gold-coloured flowers at the top, which are ſucceeded by compreſſed moon-ſhaped pods, not half ſo large as thoſe of the third ſort, but have hairy indentures like thoſe. This flowers and perfects its ſeeds about the ſame time as the former.

The fifth ſort grows naturally on the borders of the ſea in ſeveral parts of Italy; it is alſo an annual plant, with proſtrate herbaceous ſtalks about a foot long, garniſhed with trifoliate leaves, whoſe lobes are wedge-ſhaped and ſawed toward the top. The flowers are produced upon ſlender foot-ſtalks ariſing from the joints of the ſtalk; they are about an inch long, each ſuſtaining five or ſix pale yellow flowers, which are ſucceeded by ſmall, thick, moon-ſhaped pods, whoſe borders are entire, containing three or four ſmall kidney-ſhaped ſeeds in each. It flowers and ſeeds about the ſame time with the two former.

The ſixth ſort grows naturally in the Archipelago; this is an annual plant, from whoſe roots come out ſeveral oblong leaves about two inches and a half long, narrow at their baſe, but broad toward the top, where they are rounded; theſe ſpread on the ground, and between them come out the ſtalks which are ſlender, about a foot long, branching out into ſmaller, garniſhed with winged hoary leaves: thoſe on the lower part of the ſtalk are compoſed of two pair of lobes terminated by an odd one; theſe are equal in ſize, but thoſe on the upper part of the ſtalks are trifoliate. The flowers are produced at the end of the ſtalks; they are ſmall, yellow, and ſhaped like thoſe of the other ſorts, and are ſucceeded by compreſſed moon-ſhaped pods, which are acutely indented on their borders, and contain three or four kidney-ſhaped ſeeds. This plant flowers and ripens its ſeeds about the ſame time as the other.

Theſe annual ſorts are preſerved in the gardens of thoſe who are curious in botany; the ſeeds of theſe ſhould be ſown upon an open bed of freſh ground, in the places where the plants are to remain, becauſe they do not bear tranſplanting well, unleſs when they are very young. As the plants ſpread their branches on the ground, ſo they ſhould not be ſown nearer than two feet and a half aſunder; when the plants come up, they will require no other care but to keep them clean from weeds. In June they will begin to flower, and as the ſtalks and branches extend, there will be a ſucceſſion of flowers produced till the autumn; but the early flowers are ſuch as will have good ſeeds ſucceed them; for thoſe which come late in ſummer, have not time to ripen before the cold weather comes on.

The ſeventh ſort grows naturally in the iſlands of the Archipelago, in Sicily, and the warmeſt parts of Italy. This riſes with a ſhrubby ſtalk to the height of eight or ten feet, covered with a gray bark, and divides into many branches, which, while young, are covered with a hoary down; theſe are garniſhed at each joint with trifoliate leaves, ſtanding upon foot-ſtalks about an inch long; there are two or three of theſe at each joint, ſo that the branches are cloſely covered with them; the lobes are ſmall, ſpear-ſhaped, and hoary on their under ſide; theſe remain all the year. The flowers are produced on foot-ſtalks which ariſe from the ſide of the branches, they are of a bright yellow, each foot-ſtalk ſuſtaining four or five flowers; theſe are ſucceeded by compreſſed moon-ſhaped pods, each containing three or four kidney-ſhaped ſeeds.

It flowers great part of the year, and when the winters are favourable all the year; or when the plants are ſheltered in winter, they are ſeldom deſtitute of flowers; but thoſe in the open air begin to flower in April, and continue in ſucceſſion till December. Thoſe flowers which appear early in ſummer will have their ſeeds ripe in Auguſt, or the beginning of September, and the others will ripen in ſucceſſion till the cold ſtops them.

This plant may be propagated by ſowing the ſeeds upon a moderate hot-bed, or a warm border of light earth, in the beginning of April; and when the plants come up, they ſhould be carefully cleared from weeds; but they ſhould remain undiſturbed, if ſown in the common ground, till September following; but if on a hot-bed, they ſhould be tranſplanted about Midſummer into pots, placing them in the ſhade until they have taken root; after which they may be removed into a ſituation where they may be ſcreened from ſtrong winds, in which they may abide till the latter end of October, when they muſt be put into a common garden frame, to ſhelter them from hard froſts; for thoſe plants which have been brought up tenderly, will be liable to ſuffer by hard weather, eſpecially while they are young. In April following theſe plants may be ſhaken out of the pots, and placed in the full ground where they are deſigned to remain, which ſhould be in a light ſoil and a warm ſituation, in which they will endure the cold of our ordinary winters extremely well, and continue to produce flowers moſt part of the year, and retaining their leaves all the winter renders them the more valuable.

Thoſe alſo which were ſown in an open border may be tranſplanted in Auguſt following, in the ſame manner; but in doing of this you muſt be careful to take them up with a ball of earth to their roots, if poſſible, as alſo to water and ſhade them until they have taken root; after which they will require little more care than to keep them clean from weeds, and to prune off the luxuriant branches to keep them within due compaſs; but you ſhould never prune them early in the ſpring, nor late in autumn, for if froſt ſhould happen ſoon after they are pruned, it will deſtroy the tender branches, and many times the whole plant is loſt thereby.

Theſe plants have been conſtantly preſerved in the green-houſe, ſuppoſing them too tender to live thro' the winter in the open air; but I have had large plants of this kind, which have remained in a warm ſituation many years without any cover, and have been much ſtronger, and flowered better, than thoſe which were houſed; though, indeed, it will be proper to keep a plant or two in ſhelter, leſt by a very ſevere winter (which ſometimes happens in England) the plants abroad ſhould be deſtroyed.

They may alſo be propagated by cuttings, which ſhould be planted in April, upon a bed of light earth, and watered and ſhaded until they have taken root, after which they may be expoſed to the open air; but they ſhould remain in the ſame bed till July or Auguſt following, before they are tranſplanted, by which time they will have made ſtrong roots, and may be removed with ſafety to the places where they are to remain, obſerving (as was before directed) to water and ſhade them until they have taken root; after which you may train them up with ſtrait ſtems, by faſtening them to ſticks, otherwiſe they are apt to grow crooked and irregular; and when you have got their ſtems to the height you deſign them, they may then be reduced to regular heads, and with pruning their irregular ſhoots every year, they may be kept in very good order.

This plant grows in great plenty in the kingdom of Naples, where the goats feed upon it, with whoſe milk the inhabitants make great quantities of cheeſe; it alſo grows in the iſlands of the Archipelago, where the Turks uſe the wood of theſe ſhrubs to make handles for their ſabres, and the Caliogers of Patmos make their beds of this wood.

This is, as hath been before obſerved, by many people, ſuppoſed to be the Cytiſus of Virgil, Columella, and the old writers in huſbandry, which they mention as an extraordinary plant, and worthy of cultivation for fodder, from whence ſeveral perſons have recommended it as worthy of our care in England. But however uſeful this plant may be in Crete, Sicily, Naples, or thoſe warmer countries, yet I am perſuaded it will never thrive in England, ſo as to be of any real advantage for that purpoſe; for in ſevere froſt it is very ſubject to be deſtroyed, or at leaſt ſo much damaged, as not to recover its former verdure before the middle or latter end of May; and the ſhoots which are produced will not bear cutting above once in a ſummer, and then will not be of any conſiderable length; and the ſtems growing very woody, will render the cutting of it very troubleſome; ſo that, upon the whole, it can never anſwer the trouble and expence in cultivating it, nor is it worth the trial, ſince we have ſo many other plants preferable to it; though in hot, dry, rocky countries, where few other plants will thrive, this may be cultivated to great advantage, ſince in ſuch ſituations this plant will live many years, and thrive very well.

But however unfit this may be for ſuch uſes in England, yet for the beauty of its hoary leaves, which will abide all the year, together with its long continuance in flower, it deſerves a place in every good garden, where, being intermixed with ſhrubs of the ſame growth, it makes a very agreeable variety.

As there are at preſent ſo many perſons inquiſitive to know which is the true Cytiſus mentioned by the antients, I have taken the pains of tranſcribing briefly what they have ſaid as to its deſcription, by which may be judged how uncertain it is to determine in an affair where there is ſo little to be found in authors to aſſiſt us.

Theophraſtus ſays, Cytiſus is ſuch an enemy to other plants, that it will kill them, by robbing them of nouriſhment, and that the medulla of it is ſo hard and thick, that it comes the neareſt of any thing to Ebenum.

The ſhrub Cytiſus, by Ariſtomachus, the Athenian, as may be ſeen in Pliny [who ſays much the ſame as Varro and Columella, from whom probably he has taken it,] is highly commended for food for ſheep, and, being dry, for ſwine; the utility [as to health and fattening, Dal.] the ſame as that of Ervum, but the ſatiety is quicker, a four-footed animal growing fat with a little of it, ſo that cattle ſet light by their Barley.

No food makes a greater quantity, nor better milk, and it excels all things as to the diſeaſes of cattle; moreover, being given dry, or in a decoction of water mixed with wine, to nurſes whoſe milk fails, it helps very much, and makes the children ſtronger, and take to their feet ſooner; green, it is alſo good for them, or dry, if it be made moiſt.

Democritus and Ariſtomachus ſay, bees will never want food, if they have Cytiſus enough, nor is any thing cheaper.

If, when the ſeed be ſown, ſhowers are wanting, Columella directs, That it be watered the fifteen following days.

It is ſown [according to the antients] after the equinoxes. It is perfected in three years. It is mown in the vernal equinox [for it flouriſhes all the winter, Dal.] with the cheap labour of a boy, or old woman.

The Cytiſus is hoary in aſpect. If any one would expreſs its likeneſs briefly, it is a ſhrub of a broader ſort of Trefoil.

In winter, being moiſtened, ten pounds will ſatisfy a horſe, and a leſs quantity other animals. Being dry, it has more virtue, and a leſs quantity ſatisfies.

This ſhrub was found in the iſle Cythnus, thence it was tranſlated into all the Cyclades, and afterwards into the cities of Greece, where it occaſioned a great increaſe of cheeſe.

It fears not the injury of heat nor cold, nor hail nor ſnow, and Hyginus adds, nor of enemies, becauſe the wood is of no value.

Alſo Galen, in his book de Antid. writes, "Cytiſus
" is a ſhrub. In Myſia, in that part that is neareſt to
" our province, there is a tract which they call Brot-
" ton, in which there is a place full of Cytiſus, from
" the flowers of which, all agree, the bees make very
" much honey.
" It is a fruticoſe plant; it riſes to the height of a
" Myrtle."

He ſays, ſeven ſimple leaves have the faculty of digeſting, mixed with warm water, as the leaves of Mallows: thus Galen.

Cornarus too ſecurely writes, That Cytiſus either never came among the Germans, or that it periſhed long ago. From what Pliny ſays, That it was very rare in Italy in his time, he cannot perſuade me, that nothing could grow in Germany, that was ſcarce in Italy. Jo. Bauh.

Strabo, contrary to Dioſcorides, Pliny, and Galen, will have the Cytiſus to be a tree, and he likens it to the Balſamum, an odoriferous tree, which probably was the occaſion, that Cornarus thought this tree came neareſt to a ſhrub, becauſe Pliny ſaid the wood was of no value, therefore he perſuades himſelf, that it produces woody branches, not tender and ſoft, as in an herb.

But Virgil ſhews it is neither a tree nor a ſhrub, when he ſays:

" —— Non me paſcente, capellæ,
" Florentem Cytiſum, & ſalices capretis amaras."
[Buc. Eclog. 1.
" Sic Cytiſo paſtæ diſtendunt ubera vaccæ."
Eclog. 9.
" Nec Cytiſo ſaturantur apes, nec fronde capellæ."
Eclog. 10.

Virgil, I ſay, indicates very plainly in theſe verſes, that it is neither a tree nor a ſhrub, for goats do not uſe it; nor can they, if they were wont to eat flowery trees. Neither will what Cornarus ſays avail, when Pliny ſays the wood is of no value, that it muſt of neceſſity produce woody branches; nay, the contrary is rather true, that there is no value in the wood, that it bears viny pliable branches, with which the goats cannot be ſatiated.

Theocritus very plainly expreſſes it, That Cytiſus is a very grateful food to goats:

Ἡ αἶξ τὸν κύτισον, ὀλύκος τὴν αἶγα διώκει.

" Capra Cytiſum, lupus capellam ſequitur."

Which is thus imitated by Virgil:

" Torva leæna lupum ſequitur, lupus ipſe capellam:
" Florentem Cytiſum ſequitur laſciva capella."

Amatus, to avoid this difficulty, concludes Cytiſus to be between trees and ſhrubs, by the difference of genus, to be diſtinguiſhed by Pliny, that, as a tree, it may be uſed in the feminine gender, as a ſhrub in the maſculine, which is not worth the minding.

Columella uſes Cytiſus in the feminine gender, and Theocritus and others in the maſculine; as Cob. Conſt. in Lex. who writes that it was called ἀρνόφυλλον, and Theocritus calls this ſhrub κυτιλὸν, and others, κύτισον; others again τῆλις.

Of Cythnus, or, as others, of Cythiſa, the name of an iſland, as Severius has it.

Among theſe words of Dioſcorides in ſome manuſcripts, there are found, falſely written, in ſome, Telinen Triphyllon, in others Lotum Grandem.

Dioſcorides's deſcription of the Cytiſus is not ſo accurate, that from it the true Cytiſus may be aſcertained.

Although in the ſeveral ſpecies of Cytiſuſes it is hard to judge which is the legitimate Cytiſus ſpecified by the antients; the moſt ſkilful take it to be that which Maranthus has deſcribed, which is our Medica, which has been ranged under the genus of Cytiſus, by moſt of the writers before Dr. Tournefort, who eſtabliſhed the genus of Medicago, on account of the ſeed-veſſel being like that of Medica, or Snail Trefoil.

This plant grows in great plenty at Abruzzo, where the goats feed upon it, and from their milk are made great quantities of cheeſe. I have had both ſeeds and ſpecimens of the plant ſent me from thence, by perſons of the greateſt ſkill in botany, who have aſſured me, that this plant is generally ſuppoſed, by all the people of learning in that country, to be the plant mentioned by Virgil.

Trifolium fruticans, according to Dodonæus, or Polemonium, according to ſome, is improperly called, Cytiſus by many.

Trifolium candidum Dodon. by ſome is ſaid to be the Cytiſus of Columella, concerning which, ſee Lib. Hiſt. n. 9. 17. of Trifolious herbs.

Tragus writes, That their opinion is to be rejected, who interpret the Trifolium pratenſe to be a Cytiſus. Some contend the Trifolium candidum of Dodon. the Rectum Melilotum vulgarem, to be the Cytiſus of the antients, as Dodonæus ſays, but they have not hit on the truth.

Ruellius writes, That he was afraid that Marcellus took Cytiſus for Medica.

MEDICAGO. Lin. Gen. Plant. 805. Medica. Tourn. Inſt. R. H. 410. tab. 231. Snail Trefoil.

The CHARACTERS are,

The flower hath a cylindrical erect empalement of one leaf, which is cut at the brim into five equal acute ſegments. The flower is of the butterfly kind, having an oval erect ſtandard, whoſe borders are reflexed. The wings are oblong, oval, and fixed to the keel by an appendix. The keel is oblong, bifid, obtuſe, and reflexed. It hath ten ſtamina, nine of which are joined, and the other is ſingle, terminated by ſmall ſummits, and an oblong germen, which ſits upon a ſhort ſtyle, is involved with the ſtamina by the keel, and crowned by a very ſmall ſtigma. The germen afterward turns to a long compreſſed pod, twiſted into the form of a ſnail, incloſing many kidney-ſhaped ſeeds.

This genus of plants is ranged in the ſame ſection and claſs, as the former by Tournefort and Linnæus.

The Species are,

1. Medicago (*Marina*) pedunculis racemoſis, leguminibus cochleatis, ſpinoſis, caule procumbente tomentoſo. Hort. Cliff. 378. *Medicago with branching foot-ſtalks, ſnail-ſhaped prickly pods, and a trailing woolly ſtalk.* Medica Marina. Lob. Icon. 38. *Sea Medick, or Snail Trefoil.*
2. Medicago (*Scutellata*) leguminibus chochleatis, inermibus ſtipulis dentatis caule anguloſo diffuſo, foliolis oblongo ovatis acute dentatis. *Medicago with ſmooth ſnail-ſhaped pods, indented ſtipulæ, an angular diffuſed ſtalk, and oblong, oval, ſmall leaves, which are ſharply indented.* Medica ſcutellata. J. B. 2. 384. *Snail Trefoil, commonly called Snails.*
3. Mbdicago (*Tornato*) leguminibus tornatis inermibus, ſtipulis acutè dentatis foliolis ſerratis. *Medicago with a turned ſmooth pod, acute indented ſtipulæ, and the ſmall leaves ſawed.* Medica tornata minor lenis. Park. Theat. 1116. *Snail Trefoil with a ſmaller, turned, ſmooth fruit.*
4. Medicago (*Intortexta*) leguminibus cochleatis ſpinoſiſſimis aculeis utrinque tendentibus. *Medicago with very prickly ſnail-ſhaped pods, whoſe ſpines point every way.* Medica magno fructu, aculeis ſurſum & deorſum tendentibus. Tourn. Inſt. R. H. 411. *Snail Trefoil with a large fruit, whoſe ſpines point upward and downward, commonly called Hedgehog.*
5. Medicago (*Laciniata*) leguminibus chochleatis ſpinoſis, foliolis acutè dentatis tricuſpidiſque. *Medicago with prickly ſnail-ſhaped pods, whoſe lobes are acutely indented, and terminate in three points.* Medica cochleata dicarpos capſulâ rotundâ ſpinoſâ, foliis eleganter diſſectis. H. L. B. *Snail-ſhaped Trefoil, having a double fruit with a round prickly capſule, and elegant cut leaves.*

There are many other ſpecies of this genus, which grow naturally in the warm parts of Europe, and are frequently preſerved in botanic gardens for the ſake of variety; but theſe are rarely cultivated in other gardens, ſo it would be beſide my purpoſe to enumerate them here.

The firſt ſort grows naturally on the borders of the Mediterranean Sea; this is a perennial plant, with trailing woolly branches about a foot long, which are divided into ſmall branches, garniſhed with ſmall, trifoliate, downy leaves at each joint, ſtanding upon ſhort foot-ſtalks. The flowers are produced from the ſide and at the ends of the branches, in ſmall cluſters; they are of a bright yellow colour, and are ſucceeded by ſmall roundiſh ſnail-ſhaped fruit, which are downy, and armed with a few ſhort ſpines. The flowers appear in June and July, and the ſeeds ripen in September.

This plant is propagated by ſeeds, which ſhould be ſown upon a warm border of dry ſoil in the ſpring, where the plants are deſigned to remain; when the plants are come up, two or three of them may be tranſplanted into ſmall pots to be ſheltered in winter, becauſe in very ſevere froſt, thoſe which are in the open air are frequently deſtroyed; though they will endure the cold of our ordinary winters, if they are growing in a dry ſoil and a ſheltered ſituation. Thoſe plants which are left remaining, will require no other culture but to thin them where they are too cloſe, and keep them clean from weeds. This ſort may be propagated by cuttings, which may be planted in June or July, in a ſhady border, covering them cloſe with a glaſs to exclude the external air; theſe will take root in about ſix weeks time, and may then be either planted in a warm border or in pots, and treated in the ſame way as the ſeedling plants.

The ſecond ſort is an annual plant, which grows naturally in the warm parts of Europe, but in England it is frequently cultivated in gardens for the oddneſs of its fruit, which is twiſted in the form of a ſnail; and as it ripens turns to a dark brown colour, ſo as to have the appearance of ſnails feeding on the plants at a diſtant view. This hath trailing branches; the flowers are of a pale yellow, and come out from the ſide of the branches. Theſe appear in June and July, and the ſeeds ripen in the autumn. It is propagated by ſeeds, which ſhould be ſown in the middle of April, where the plants are to remain; and the plants ſhould be thinned where they are too cloſe, and kept clean from weeds, which is all the culture they require.

The third ſort is alſo an annual plant, which grows in the ſame countries as the former. This hath trailing branches, and yellow flowers like the ſecond ſort, but the fruit is much longer and cloſer twiſted, ſo as to reſemble the figure of a veſſel called a pipe, being leſs at each end than in the middle. This is frequently kept in gardens for the ſake of variety, and may be propagated and treated in the ſame way as the ſecond ſort.

The fourth ſort is an annual plant, which was formerly more cultivated in the Engliſh gardens than at preſent. The ſtalks, leaves, and flowers, are like thoſe of the two former ſorts, but the fruit is much larger, and cloſely armed with long ſpines like a hedgehog, from whence it had the title; theſe ſpines point every way, ſo that it is difficult to handle the fruit without ſmarting for it. This is propagated by ſeeds in the ſame way as the ſecond ſort, and the plants require the ſame treatment. It flowers in June, and the ſeeds ripen in September.

The fifth ſort grows naturally in Syria; it is an annual plant, with trailing ſtalks like the former; the lobes of the trifoliate leaves are wedge-ſhaped, ſharply indented on the edges, and at the top have three acute points. The flowers are of a pale yellow, and the fruit is ſnail-ſhaped, but ſmall, armed with many weak ſpines. It flowers about the ſame time with the former, and may be cultivated in the ſame way.

MEDLAR. See Meſpilus.

MELAMPYRUM. Tourn. Inſt. R. H. 173. tab. 78. Lin. Gen. Plant. 660. Μελάμπυρον, of μέλας, black, and πυρὸς, Wheat.] Cow Wheat.

The Characters are,

The flower has a permanent empalement of one leaf, which is tubulous, cut into four ſegments at the brim. The flower is of the lip kind, having an oblong recurved tube compreſſed at the brim; the upper lip is formed like a helmet, and is compreſſed and indented at the top; the under lip is plain, erect, and cut into three ſegments at the top, which are equal and obtuſe. It hath four awl-ſhaped ſtamina which are curved under the upper lip, two of which are ſhorter than the other, terminated by oblong ſummits, and in the center is ſituated an acute-pointed germen, ſupporting a ſingle ſtyle crowned by an obtuſe ſtigma. The empalement afterward turns to an oblong acute-pointed capſule with two cells, incloſing two pretty large oval ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's fourteenth claſs, which contains thoſe plants whoſe flowers have two long and two ſhorter ſtamina, and the ſeeds are included in a capnſule.

The Species are,

1. Melampyrum (*Pratenſe*) floribus ſecundis lateralibus, conjugationibus remotis, corollis clauſis. Flor. Suec. 513. *Cow Wheat with fruitful foot-ſtalks of flowers ſtanding at a diſtance, and the petals ſhut.* Melampyrum luteum latifolium. C. B. P. 234. *Broad-leaved yellow Cow Wheat.*
2. Melampyrum (*Criſtatum*) ſpicis quadrangularibus bracteis cordatis compactis denticulis imbricatis. Flor. Suec. 510. *Cow Wheat with quadrangular ſpikes, and heart-ſhaped bracteæ, which are imbricated.* Melampyrum luteum anguſtifolium. C. B. P. 234. *Yellow narrow-leaved Cow Wheat.*
3. Melampyrum (*Arvenſe*) ſpicis conicis laxè bracteis dentato-ſetaceis. Flor. Seuc. 511. *Cow Wheat with looſe conical ſpikes, and briſtly indented bractea.* Melampyrum purpuraſcente comâ. C. B. P. 234. *Cow Wheat with purpliſh tops.*
4. Melampyrum (*Nemoroſum*) floribus ſecundis lateralibus bracteis dentato cordato lanceolatis, ſummis, coloratis ſterilibus, calycibus lanatis. Flor. Suec. 512. *Cow Wheat with fruitful lateral flowers, heart ſpear-ſhaped bracteæ, ſterile coloured tops, and woolly empalements.*

ments. Melampyrum comâ cæruleâ. C. B. P. 234. *Cow Wheat with blue tops.*

Theſe plants are ſeldom cultivated in gardens. The firſt ſort grows naturally in woods in many parts of England. The ſecond ſort grows plentifully in Bedfordſhire and Cambridgeſhire. The fourth ſort grows in the northern parts of Europe. The third ſort grows naturally in ſome of the ſandy lands in Norfolk, tho' not in great plenty; but in Weſt Friezland and Flanders, it grows very plentifully among the Corn; and Cluſius ſays, it ſpoils their bread, making it dark; and that thoſe who eat of it uſed to be troubled with heavineſs of the head, in the ſame manner as if they had eaten Darnel or Cockle: but Mr. Ray ſays, He has eaten of this bread very often, but could never perceive that it gave any diſagreeable taſte, or that it was accounted unwholeſome by the country people, who never endeavour to ſeparate it from the Corn: and Tabernæmontanus declares, he has often eaten it without any harm; and ſays, it makes a very pleaſant bread. It is a delicious food for cattle, particularly for fattening of oxen and cows, for which purpoſe it may be cultivated.

The ſeeds of theſe plants ſhould be ſown in the autumn ſoon after they are ripe, otherwiſe it ſeldom grows the firſt year; when the plants come up, they muſt be weeded in the ſpring while young, and as ſoon as they begin to ſhew their flowers, the cattle may be fed upon it; but they ſhould be confined to a certain ſpace, and not permitted to run over the whole field to trample it down, which would deſtroy a great part of it.

The third and fourth ſorts make a pretty appearance, with their purple and blue tops, during the months of July and Auguſt. They are all of them annual plants.

MELANTHIUM, Star-flower.

The Characters are,

The flower has no empalement (unleſs the corolla is ſo called) it hath ſix oblong, oval, ſpreading petals, which are permanent, and ſix ſlender erect ſtamina inſerted above the tails, with globular ſummits, with a ſtreaked globular germen, ſupporting three curved diſtinct ſtyles, crowned by obtuſe ſtigma; the germen afterward turns to an oval capſule, having three cells, which are united within, containing ſeveral oval compreſſed ſeeds.

This genus of plants is ranged in the third ſection of Linnæus's ſixth claſs, intitled Hexandria Trigynia, the flower having ſix ſtamina and three ſtyles.

The Species are,

1. Melanthium (*Virginicum*) petalis unguiculatis. Lin. Sp. Plant. 483. *Star-flower with tender nail-ſhaped petals.* Aſphodelo affinis Floridana, ramoſo caule, floribus ornithogali obſoletis. Pluk. tab. 434. f. 8.
2. Melanthium (*Sibericum*) petalis ſeſſilibus. Amœn. Acad. 2. p. 349. *Star-flower with ſeſſile petals.* Ornithogalum ſpicis florum longiſſimis ramoſis. Flor. Siber. p. 45.
3. Melanthium (*Punctatum*) petalis punctatis, foliis cucullatis. Amœn. Acad. 6. *Star-flower with punctuated petals, and hooded leaves.*

The firſt ſort grows naturally in Virginia and in other parts of North America, but being a plant of little beauty, is ſeldom cultivated except in botanic gardens; the flower-ſtalks of this riſes from ſix to eight inches high, branching upward into three or four diviſions, garniſhed below the flower with two or three linear leaves. The flowers are compoſed of ſix ſpreading petals of a duſky worn-out colour, which are rarely ſucceeded by ſeeds in England.

If the roots of this plant are planted in a border of light earth, not too dry, they will thrive and produce their flowers here, but ſeldom increaſe.

The ſecond ſort grows naturally in Siberia, ſo is at preſent a ſtranger in England, but may be propagated here (if once obtained) by planting the bulbous roots in an eaſt border.

The third ſort grows at the Cape of Good Hope, ſo is too tender to thrive in the open air in England. But if the roots are planted in a border, covered in winter with a garden frame, and treated in the ſame way as is directed for the Ixia, they will thrive and flower annually.

MELASTOMA. Lin. Gen. Plant. 481. Groſſularia. Sloan. Hiſt. Jam. Plum. Sp. 18. The American Gooſeberry-tree, vulgò.

The Characters are,

The flower has a permanent empalement of one leaf, ſwelling like a bladder, and obtuſe. It hath five roundiſh petals, which are inſerted into the border of the empalement, and ten ſhort ſtamina, terminated by long erect ſummits a little curved. Under the flower is ſituated a roundiſh germen, ſupporting a ſlender ſtyle, crowned by an incurved indented ſtigma. The germen afterward turns to a berry with five cells, covered by the empalement which crowns it, and contains many ſmall ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's tenth claſs, intitled Decandria Monogynia, which includes thoſe plants whoſe flowers have ten ſtamina and one ſtyle.

The Species are,

1. Melastoma (*Plantaginis folio*) foliis denticulatis ovatis acutis. Lin. Sp. Plant. 389. *Melaſtoma with oval, acute-pointed, indented leaves.* Groſſularia Americana, plantaginis folio ampliſſimo. Plum. Sp. 18.
2. Melastoma (*Acinodendron*) foliis denticulatis ſubtrinerviis ovatis acutis. Lin. Sp. Plant. 558. *Melaſtoma with oval indented leaves ending in acute points, having three veins.* Groſſularia alia plantaginis folio, fructu rariore violaceo. Plum. Sp. 18.
3. Melastoma (*Hirta*) foliis denticulatis quinquenervibus, ovato-lanceolatis caule hiſpido. Lin. Sp. 390. *Melaſtoma with ſpear-ſhaped indented leaves, with five veins, and a prickly ſtalk.* Groſſularia plantaginis folio anguſtiore hirſuto. Plum. Sp. 18.
4. Melastoma (*Holoſericea*) foliis integerrimis trinerviis oblongo-ovatis tomentoſis racemis brachiatis, ſpicis bipartitis. Lin. Sp. 559. *Melaſtoma with very entire oblong oval leaves, which are woolly on their under ſide, and ſpikes of flowers dividing in two parts.* Arbor racemoſa Braſiliana, folio Malabathri. Breyn. Cent. tab. 2 & 3.
5. Melastoma (*Groſſularioides*) foliis lanceolatis utrinque glabris nervis tribus ante baſin coëuntibus. Hort. Cliff. 162. *Melaſtoma with ſpear-ſhaped leaves ſmooth on both ſides, and three veins which join before they reach the baſe.* Groſſularia fructu non ſpinoſo, Malabathri foliis oblongis, floribus herbaceis racemoſis, fructu nigro. Sloan. Cat. 165.
6. Melastoma (*Bicolor*) foliis lanceolatis, nervis tribus longitudinalibus, ſubtus glabris coloratis. Hort. Cliff. 162. *Melaſtoma with ſpear-ſhaped leaves having three longitudinal veins, ſmooth and coloured on their under ſide.*
7. Melastoma (*Malabathrica*) foliis lanceolato-ovatis quinquenervibus ſcabris. Flor. Zeyl. 171. *Melaſtoma with ſpear-ſhaped oval leaves which are rough, and have five veins.* Melaſtoma quinque nervia hirta major, capitulis ſericeis villoſis. Burm. Zeyl. 155. tab. 73.
8. Melastoma (*Lævigata*) foliis oblongo-ovatis minutiſſimè dentatis infernè ſericeis quinquenervibus, floribus racemoſis. *Melaſtoma with oblong oval leaves, having very ſmall indentures on the edges, and ſilky on their under ſide, with five veins, and flowers growing in long bunches.* Groſſulariæ fructu, arbor maximo non ſpinoſa, Malabathri folio maximo inodora, flore racemoſo albo. Sloan. Cat. Jam. 165.
9. Melastoma (*Petiolatis*) foliis denticulatis ovatis acuminatis, infernè nitidiſſimis, petiolis longiſſimis. *Melaſtoma with oval acute-pointed leaves, which are indented on their edges, very ſhining on their under ſide, and have very long foot-ſtalks.*
10. Melastoma (*Umbellata*) foliis cordatis acuminatis integerrimis, infernè incanis, floribus umbellatis. *Melaſtoma with heart-ſhaped, acute-pointed, entire leaves, hoary on their under ſide, and flowers growing in umbels.* Sambucus Barbadenſis dicta, foliis ſubincanis. Pluk. Phyt. tab. 221. fol. 6.
11. Melastoma (*Racemoſa*) foliis oblongo-cordatis acuminatis, denticulato-ſerratis, floribus racemoſis ſparſis.

ſis. *Melaſtoma with oblong, heart-ſhaped, acute-pointed leaves, having ſawed indentures, and flowers growing thinly in long bunches.*

12. MELASTOMA (*Verticillata*) foliis ovato-lanceolatis, quinquenervibus, ſubtus aureis, floribus verticillatis, caule tomentoſo. *Melaſtoma with oval ſpear-ſhaped leaves having five veins, which are of a gold colour on their under ſide, and flowers growing in whorls, with a woolly ſtalk.*

13. MELASTOMA (*Acuta*) foliis lanceolatis acutis denticulatis infernè incanis trinervibus, floribus racemoſis. *Melaſtoma with acute ſpear-ſhaped leaves which are indented on their edges, hoary on their under ſide, have three veins, and flowers growing in bunches.*

14. MELASTOMA (*Glabra*) foliis ovato-lanceolatis acuminatis integerrimis, utrinque glabris trinervibus, floribus racemoſis. *Melaſtoma with entire, oval, ſpear-ſhaped leaves ending in acute points, having three veins, and ſmooth on both ſides, with flowers growing in long bunches.* Arbor Syrinamenſis, canellæ folio utrinque glabro. Pluk. Phyt. tab. 249. fol. 5.

15. MELASTOMA (*Quinquenervia*) foliis ovatis quinquenervibus ſcabris, floribus racemoſis alaribus. *Melaſtoma with oval rough leaves having five veins, and flowers growing in bunches from the ſides of the branches.*

16. MELASTOMA (*Octandria*) foliis lanceolatis trinervibus glabris, marginibus hiſpidis. *Melaſtoma with ſmooth ſpear-ſhaped leaves having three veins, and hairy prickles on the border.*

17. MELASTOMA (*Aſpera*) foliis ovatis quinquenervibus glabris, marginibus hiſpidis. *Melaſtoma with oval ſmooth leaves, having five veins, and hairy prickly borders.*

18. MELASTOMA (*Scabroſa*) foliis ovato-lanceolatis ſcabris acuminatis quinquenervibus, floribus racemoſis. *Melaſtoma with oval, ſpear-ſhaped, acute-pointed leaves, having five veins, and flowers growing in long bunches.*

The title of this genus of plants was given to it by Profeſſor Burman, of Amſterdam, in the Theſaurus Zeylanicus; ſome of theſe plants have been titled Sambucus, others Chriſtophoriana, and to ſome of the ſpecies Dr. Plukenet gave the title of Acidendron; but Sir Hans Sloane and Father Plumier, gave them the title of Groſſularia, from whence I have applied the Engliſh name of Gooſeberry to them, which is the name by which ſome of the ſorts are known in America.

The firſt ſort riſes about four or five feet high, the ſtem and branches being covered with long ruſſet hairs; the leaves are placed on the branches oppoſite; they are five inches long and two broad, and are alſo covered with the ſame ruſſet down, having five ribs or veins running through the leaves from end to end, but the three inner join before they reach the baſe, with ſmall tranſverſe ribs; the fruit is produced at the end of the ſhoots, which is a pulpy blue berry, as large as a Nutmeg.

The ſecond ſort grows to be a large tree, having many crooked branches, covered with a brown bark, the leaves placed oppoſite on the branches; theſe are ſmooth, entire, and above five inches long, and two broad in the middle, with three deep veins running through them; both ſides of theſe leaves are of a light green and ſmooth, and are ſharply indented on their edges, ending in acute points. The fruit grows in looſe ſpikes at the end of the branches; they are thinly placed on the ſpikes, and are of a Violet colour.

The third ſort grows to the height of twenty feet, with a large trunk, covered with a ruſſet bark: the leaves of this tree are very large, being above ſeven inches long, and three and a quarter broad, of a dark ruſſet colour on their upper ſide, but of a yellowiſh ruſſet on their under, ſoft to the touch, having a ſoft down over them; the ſtalks are covered with rough hairs, and the leaves are placed by pairs on the branches, which make a beautiful appearance when the trees are viewed at a diſtance.

The fourth ſort ſeldom grows more than eight or ten feet high, the leaves are about four inches long, having three veins, which join before they reach the baſe; they are entire, and are of a ſattin colour on their under ſide, but of a light green on their upper; theſe are placed by pairs on the branches.

The fifth ſort ſeldom grows more than ſeven or eight feet high, ſpreading out into many branches, which are covered with a ſmooth purple bark; they are ſlender, and are garniſhed with ſpear-ſhaped leaves, five inches long and two broad in the middle, where they are broadeſt; they are ſmooth on both ſides, their edges are entire, and they terminate in acute points. The flowers are produced in pretty long hanging bunches, of an herbaceous colour, with long ſtyles which are ſtretched out a good length beyond the petals; and are permanent; the fruit is ſmall, and black when ripe.

The ſixth ſort riſes four or five feet high, dividing into many ſlender branches, which are ſmooth, and garniſhed with ſpear-ſhaped leaves three inches long, and one and a quarter broad, of a lucid green on the upper ſide, but white on the under, having three longitudinal veins which join before they reach the baſe; theſe are entire, and placed alternately on the branches. The flowers are produced in a looſe panicle at the end of the branches; they are ſmall, white, and have pretty long tubes; theſe are ſucceeded by ſmall purple fruit.

The ſeventh ſort riſes with an angular ſtalk ſix or ſeven feet high, ſending out branches oppoſite, which are garniſhed with ſpear-ſhaped, oval, rough leaves, placed by pairs; they are hairy, of a dark green on their upper ſide, but of a pale green on their under. The flowers are produced at the end of the branches, two or three ſtanding together; they are large, and of a Roſe colour, inclining to purple, ſitting in large hairy empalements; theſe are ſucceeded by roundiſh purple fruit crowned by the empalement, which are filled with a purple pulp ſurrounding the ſeeds.

The eighth ſort grows to the height of twenty feet, with a large ſtrait ſtem, covered with a gray bark, and at the top divides into many angular branches; theſe are garniſhed with oblong oval leaves near a foot long, and ſix inches broad in the middle, of a dark green on their upper ſide, but ſilky on their under, with five ſtrong longitudinal veins; they are indented on their edges, and placed oppoſite. The flowers are produced in looſe long bunches at the end of the branches; theſe are white, and are ſucceeded by roundiſh purple fruit, filled with pulp, in which the ſeeds are lodged.

The ninth ſort riſes with a ſtrong erect ſtalk near thirty feet high, covered with a gray bark, dividing at the top into ſeveral angular compreſſed branches, which are garniſhed with oval leaves indented on their edges; they are ſeven inches long and almoſt five broad, ſtanding by pairs oppoſite on very long footſtalks, of a lucid green on their upper ſide, but of a pale gold colour and ſattiny on their under, with five ſtrong longitudinal veins, and a great number of ſmaller tranſverſe ones. The flowers are produced in looſe panicles at the end of the branches; they are white, and are ſucceeded by purple fruit, about the ſame ſize as thoſe of the former.

The tenth ſort riſes with a ſhrubby ſtalk ten or twelve feet high, covered with a hairy bark, and divides into many branches toward the top, which are garniſhed with heart-ſhaped leaves ending in acute points; they are five inches long and three broad toward their baſe, entire in their borders, of a dark green on their upper ſide, but hoary on their under, with five longitudinal veins, and many ſmaller tranſverſe ones; theſe are placed oppoſite, and ſtand upon hairy footſtalks, two inches and a half in length. The flowers are produced at the end of the branches, in a ſort of umbel; they are of a pale Roſe colour and pretty large, ſitting on hairy empalements; theſe are ſucceeded by ſmall black fruit, a little larger than Elder-berries.

The eleventh ſort riſes with a ſhrubby ſtalk about eight or nine feet high, covered with a dark brown bark, and divides at the top into many ſtraggling branches, which are garniſhed with oblong heart-ſhaped leaves ſix inches long, and three broad toward their baſe, ending in acute points, indented on their edges with ſharp ſerratures; they are ſmooth on both ſides, and of a light green colour. The flowers are produced in very looſe bunches at the end of the branches; they are ſmall, of an herbaceous colour, and are ſucceeded by ſmall fruit, of a dark colour when ripe.

The twelfth ſort riſes with a ſhrubby ſtalk five or ſix feet high, dividing into many ſmaller branches, which are covered with a hairy woolly bark, of a ruſty iron colour; theſe are garniſhed with oval ſpear-ſhaped leaves, one inch and a half long, and three quarters of an inch broad in the middle; they are of a dark green on their upper ſide, and of a ruſty iron colour on their under, having five longitudinal veins; they are placed oppoſite, and ſit cloſe to the branches. The flowers come out in whorls at the joints of the ſtalks; they are ſmall, of a purpliſh colour, and are ſucceeded by ſmall black fruit.

The thirteenth ſort is a low ſhrub, ſeldom riſing more than three feet high, dividing at the bottom into ſlender branches, which are garniſhed with ſpear-ſhaped leaves, ending in acute points; theſe are five inches long, and one and a half broad in the middle, ſawed on their edges, of a dark green on their upper ſide, but of a hoary white on their under, having three longitudinal veins; they are placed oppoſite, upon ſhort foot-ſtalks. The flowers are produced in looſe bunches at the end of the branches; they are white, and ſucceeded by ſmall purple fruit.

The fourteenth ſort hath a ſhrubby ſtalk eight or nine feet high, divided toward the top into many ſlender branches which are ſmooth, garniſhed with oval ſpear-ſhaped leaves, which are ſeven inches long and three broad, ending in acute points; they are entire on their edges, and ſmooth on both ſides, ſtanding oppoſite, and have three longitudinal veins. The flowers are produced in looſe panicles at the end of the branches, and are ſucceeded by very ſmall purple fruit.

The fifteenth ſort riſes with ſeveral ſhrubby ſtalks five or ſix feet high, dividing into ſeveral crooked branches, garniſhed with oval leaves three inches long, and almoſt as much broad, having five longitudinal veins; they are rough, of a dark green on their upper ſide, but of a pale green on their under, indented on their edges, ſtanding upon very hairy foot-ſtalks; they are ſometimes oppoſite, and at others alternate, on the branches. The flowers are produced in very looſe bunches, which come out from the ſide of the ſtalks; they are ſmall, of an herbaceous colour, and are ſucceeded by ſmall purpliſh fruit, filled with very ſmall ſeeds.

The ſixteenth ſort riſes with a ſhrubby ſtalk ſeven or eight feet high, and divides into many ſmooth branches, which are garniſhed with ſpear-ſhaped leaves about four inches long, and one inch and a quarter broad in the middle; they are ſmooth on both ſides, of a dark green colour, and have three longitudinal veins; the edges of theſe leaves are cloſely ſet with briſtly ſtinging hairs. The flowers are produced in looſe bunches at the end of the branches; they are ſmall, of a purpliſh colour, and are ſucceeded by very ſmall black fruit.

The ſeventeenth ſort is in many parts like the former, but the leaves are oval, a little more than two inches long, and one and a quarter broad; theſe have five longitudinal veins, and are ſmooth on both ſides, of a dark green colour, and ſtand oppoſite on ſhort foot-ſtalks. The flowers grow in looſe bunches at the end of the branches, they are larger than thoſe of the former ſort, but are of the ſame colour. The edges of the leaves of this ſort are cloſely ſet with ſtinging hairs, as thoſe of the other.

The eighteenth ſort riſes with a ſhrubby ſtalk eight or nine feet high, dividing into branches ſtanding oppoſite, as do alſo the leaves, which are ſeven inches long and three broad; rough on their ſurface, entire on their edges, ending in acute points; they are of a light green on both ſides, and ſtand upon ſhort foot-ſtalks. The flowers are produced in pretty large looſe panicles at the end of the branches; they are ſmall, white, and are ſucceeded by ſmall, round, purple fruit.

All the ſorts are natives of the warm parts of America, where there are many more ſpecies than are here enumerated. Moſt of theſe here mentioned, were found by the late Dr. Houſtoun, growing naturally in Jamaica, from whence he ſent many of their ſeeds to Europe, ſome of which ſucceeded; but moſt, if not all the plants which were raiſed from them, were loſt in the ſevere winter in 1740, ſince which time they have not been recovered in Europe.

There is great beauty in the diverſity of the leaves of theſe plants, many of them being very large, and moſt of them are of different colours on the two ſurfaces, their under ſide being either white, gold colour, or ruſſet, and their upper of different ſhades of green, ſo that they make a fine appearance in the hot-houſe all the year; indeed, their flowers have no great beauty to recommend them, but yet for the ſingular beauty of their leaves, theſe plants deſerve a place in all curious collections, as much as moſt other ſorts.

There are very few of theſe plants at preſent in any of the European gardens, which may have been occaſioned by the difficulty of bringing over growing plants from the Weſt-Indies; and the ſeeds being ſmall when they are taken out of the pulp, ſoon become dry, ſo ſeldom ſucceed. The beſt way to obtain theſe plants is, to have the entire fruits put up in dry ſand as ſoon as they are ripe, and forwarded by the ſooneſt conveyance to England; theſe ſhould be immediately taken out when they arrive, and the ſeeds ſown in pots of light earth, and plunged into a moderate hot-bed of tanners bark. When the plants come up, and are fit to remove, they muſt be each planted into a ſmall pot of light earth, and plunged into the tan-bed; and may afterward be treated in the manner directed for the ANNONA, to which I ſhall deſire the reader to turn, to avoid repetition.

MELIA. Lin. Gen. Plant. 473. Azederach. Tourn. Inſt. R. H. 616. tab. 387. The Bead-tree.

The CHARACTERS are,

The empalement of the flower is ſmall, erect, and of one leaf, cut into five points at the top, which are obtuſe. The flower hath five long, narrow, ſpear-ſhaped petals which ſpread open, and a cylindrical nectarium of one leaf, the length of the petals, indented at the brim in ten parts. It has ten ſmall ſtamina inſerted in the top of the nectarium, terminated by ſummits which do not appear above it, with a conical germen ſupporting a cylindrical ſtyle, crowned by an obtuſe indented ſtigma. The germen afterward turns to a ſoft globular fruit, including a roundiſh nut having five rough furrows, and five cells, each containing one oblong ſeed.

This genus of plants is ranged in the firſt ſection of Linnæus's tenth claſs, intitled Decandria Monogynia, which includes thoſe plants whoſe flowers have ten ſtamina and one ſtyle.

The SPECIES are,

1. MELIA (*Azedarach*) foliis bipinnatis. Flor. Zeyl. 162. *Melia with double winged leaves.* Azederach. Dod. Pempt. 848. *The Bead-tree, or Falſe Sycamore.*
2. MELIA (*Azedirachta*) foliis pinnatis. Hort. Cliff. 161. *Melia with winged leaves.* Olea Malabarica, fraxini folio. Pluk. Alm. 269.

The firſt ſort grows naturally in Syria, from whence it was brought to Spain and Portugal, where it is now become as common almoſt, as if it were a native of thoſe countries. This in warm countries grows to a large tree, ſpreading out into many branches, which are garniſhed with winged leaves, compoſed of three ſmaller wings, whoſe lobes are notched and indented on their edges; they are of a deep green on their upper ſide, and paler on their under. The flowers come out from the ſide of the branches in long looſe bunches; they are compoſed of five long, narrow, ſpear-ſhaped petals, of a blue colour, and are ſucceeded by oblong fruit as large as a ſmall Cherry, green at firſt, but when ripe changes to a pale yellow, incloſing a nut with five deep furrows, having four or five cells, in each of which is lodged one oblong ſeed. This produces its flowers in England in July, but are not often ſucceeded by ſeeds here; it drops its leaves in the autumn, and puts out freſh in the ſpring. The pulp which ſurrounds the nut, is ſaid to have a deadly quality if eaten; and if mixed with greaſe, and given to dogs, it will kill them. The nuts are bored through, and ſtrung by the Roman Catholics to ſerve as beads.

There has been of late years ſome of theſe plants introduced to the iſlands in the Weſt-Indies, where I am informed they continue flowering, and produce their fruit moſt part of the year. The fruit I have received from thence by the title of Indian Lilac, from which I have raiſed many of the plants, and find them to be the ſame as that from Syria.

This ſort is propagated by ſeeds (which may be obtained from Italy or Spain, where theſe trees annually produce ripe fruits in the gardens where they are planted:) the ſeeds or berries ſhould be ſown in pots filled with good freſh light earth, and plunged into a moderate hot-bed of tanners bark, where (if the ſeeds are freſh) they will come up in about a month or five weeks time. When the plants are come up they ſhould be frequently watered, and ſhould have a large ſhare of free air, by raiſing the glaſſes every day; in June they ſhould be expoſed to the open air, in a well ſheltered ſituation, that they may be hardened before winter. In October the pots ſhould be removed under a hot-bed frame, where they may enjoy free open air when the weather is mild, and be covered in hard froſt. During the winter ſeaſon they muſt be refreſhed gently with water, but by no means repeat this too often, nor give them too much at a time; for their leaves being off, they will not be in a condition to throw off a ſuperfluity of moiſture.

In March following, you may ſhake out the plants from the ſeed-pots and divide them, planting each into a ſeparate ſmall pot, filled with light freſh earth, plunging them into a moderate hot-bed, which will greatly promote their rooting, and increaſe their growth, but they muſt not be drawn too much; and in June you ſhould remove them out into the open air as before, and during the three or four winters, while the plants are young, you muſt ſhelter them, to ſecure them from the cold; but when the plants are grown pretty large and woody, they will endure to be planted in the open air againſt a ſouth wall. The beſt ſeaſon for this is in April, at which time you ſhould ſhake them out of the pots, being careful not to break the earth from the roots, but only pare off with a knife the outſide of the ball of earth; then open your holes and put in the plants, cloſing the earth to their roots, obſerving if the weather is dry, to give them ſome water, which ſhould be repeated twice a week until the plants have taken root; but you muſt obſerve to plant them on a dry ſoil, otherwiſe they will be liable to miſcary in ſevere froſty weather.

The ſecond ſort grows naturally in India, where it becomes a large tree; the ſtem is thick, the wood of a pale yellow, and the bark of a dark purple colour and very bitter. The branches extend wide on every ſide, which are garniſhed with winged leaves, compoſed of five or ſix pair of oblong acute-pointed lobes, terminated by an odd one; theſe are ſawed on their edges, of a light green colour, and a ſtrong diſagreeable odour; they ſtand upon pretty long footſtalks, which come out ſometimes oppoſite, and at others they are alternate. The flowers are produced in long branching panicles which proceed from the ſide of the branches; they are ſmall, white, and ſit in ſmall empalements, which are cut in five acute ſegments; theſe are ſucceeded by oval fruit of the ſize of ſmall Olives, which are green, afterward yellow, and when ripe, they change to a purple colour; the pulp which ſurrounds the nut is oily, acrid, and bitter; the nut is white, and ſhaped like that of the former. It grows in ſandy land, both in India and the iſland of Ceylon, where it is always green, and produces flowers and fruit twice a year.

This ſort is now very rare in England, and alſo in the Dutch gardens, where ſome years paſt it was more common; it is propagated by ſeeds in the ſame way as the other ſort, but being much tenderer, the plants ſhould be kept conſtantly in the tan-bed while young. In the ſummer they may be placed under a frame, but in winter they muſt be removed into the bark-ſtove, and treated in the ſame way with other plants from the ſame countries. When the plants have obtained ſtrength, they may be treated more hardily, by placing them in winter in a dry ſtove, and in the middle of ſummer they may be placed abroad for two or three months in a warm ſheltered ſituation, but they ſhould not remain too long abroad; and during the winter ſeaſon they ſhould be ſparingly watered: with this management the plants will produce flowers annually, and as they retain their leaves all the year, they are ornamental in winter in the ſtove.

The firſt ſort is commonly called, Zizyphus alba, in Portugal and Spain, and in Italy, Pſeudocycamorus. It was by moſt of the modern botaniſts titled, Azederach, but Dr. Linnæus has altered it to this of Melia, which was by Theophraſtus applied to a ſpecies of Aſh.

MELIANTHUS. Tourn. Inſt. R. H. 430. tab. 245. Lin. Gen. Plant. 712. [μελίανθος, of μέλι, honey, and ἄνθος, a flower.] Honey Flower.

The Characters are,

The flower has a large, coloured, unequal empalement, divided into five ſegments; the two upper are oblong and erect, the lower is ſhort, and ſhaped like a bag. The middle are ſpear-ſhaped and oppoſite. It hath four narrow ſpear-ſhaped petals, reflexed at their points, ſpreading open outward, and ſhaped like the empalement into two lips, connected on their ſides. It has a nectarium of one leaf, ſituated in the lower ſegment of the empalement, and faſtened with it to the receptacle; it is ſhort, compreſſed on the ſides, and cut on the margin. It hath four erect awl-ſhaped ſtamina, the two under being ſomewhat ſhorter than the other, terminated by oblong heart-ſhaped ſummits. In the center is ſituated a four-cornered germen, ſupporting an erect ſtyle, crowned by a quadrifid ſtigma. The germen afterward becomes a quadrangular capſule with diſtended cells, divided by partitions in the center, each containing one almoſt globular ſeed, fixed to the center of the capſule.

This genus of plants is ranged in the ſecond ſection of Linnæus's fourteenth claſs, which includes thoſe plants whoſe flowers have two long and two ſhorter ſtamina, and their ſeeds are included in empalemnets.

The Species are,

1. Melianthus (*Major*) ſtipulis ſolitariis petiolo adnatis. Hort. Cliff. 492. *Honey Flower with ſingle ſtipulæ growing cloſe to the foot-ſtalk.* Melianthus Africanus. H. L. B. 414. *Greater African Honey Flower.*
2. Melianthus (*Minor*) ſtipulis geminis diſtinctis. Hort. Cliff. 492. *Smaller Honey Flower with two diſtinct ſtipulæ.* Melianthus Africanus minor fœtidus. Com. Rar. Pl. 4. tab. 4.

The firſt ſort grows naturally at the Cape of Good Hope, from whence it was brought to Holland in the year 1672; this hath a ligneous perennial root, which ſpreads far on every ſide, from which ariſe many ligneous ſtalks which riſe four or five feet high, and are herbaceous toward the top, where they are garniſhed with large winged leaves, which embrace the ſtalks with their baſe, where they have a large ſingle ſtipulæ faſtened on the upper ſide of the foot-ſtalk, with two ears at the baſe, which alſo embrace the ſtalk. The leaves have four or five pair of very large lobes, terminated by an odd one; theſe are deeply jagged on their edges into acute ſegments, and between the lobes runs a double leafy border or wing on the upper ſide of the midrib, ſo as to connect the baſe of the lobes together; theſe are alſo deeply jagged in the ſame manner as the lobes; they are of a gray colour. The flowers are produced in pretty long ſpikes, which ariſe from between the leaves toward the top of the ſtalks; they are of a brown or chocolate colour, and are formed like the lip flowers, but have four narrow petals, in which it differs from the other plants of this claſs with lip flowers; theſe are ſucceeded by oblong four-cornered capſules, divided by a central partition into four cells, each containing one roundiſh ſeed; this plant flowers in June, but unleſs the ſeaſon proves warm, they are not ſucceeded by ſeeds in England.

This plant was formerly preſerved in green-houſes as a tender exotic, but if planted in a dry ſoil and a warm ſituation, it will endure the cold of our ordinary winters very well; and if in a ſevere froſt the tops of them ſhould be deſtroyed, yet the roots will abide, and put forth again the ſucceeding ſpring, ſo that there is no great danger of loſing it; and the plants which grow in the open air always flower much better than thoſe which are preſerved in the green-houſe, as they are leſs drawn, which always is hurtful to the flowering of plants; for it rarely happens that any of the plants of this ſort, which are placed in the green-houſe do flower, for they are apt to draw up tall and weak, which prevents their flowering, and thoſe branches which produce flowers, generally decay ſoon after; ſo that although the ſtems become woody, yet they are not of long duration, but the roots ſpread where they have room, and ſend out a great number of ſtalks annually; and when the plants grow in the full ground, moſt of thoſe ſtalks which are not injured by froſt, ſeldom fail to flower the ſpring following, ſo that the ſureſt method to have them flower, is to cover the ſhoots of theſe plants in froſty weather with Reeds or mats, to prevent their tops being killed by the cold; therefore it is the beſt way to plant them cloſe to a good aſpected wall, and on a dry rubbiſh, in which they will not ſhoot ſo vigorous as in good ground, ſo will be leſs ſucculent, and therefore not ſo liable to ſuffer by cold; but if the winter proves ſevere, the ſtalks may be faſtened up to the wall, and covered to protect them; for want of this care the ſtalks are frequently killed to the ground in winter, ſo that there is ſeldom any flowers produced.

This plant may be propagated by taking off its ſuckers or ſide ſhoots, any time from March to September, obſerving to chuſe ſuch as are furniſhed with fibres, and after they are planted and taken root, they will require no farther care but to keep them clear from weeds: they may be alſo propagated by planting cuttings, during any of the ſummer months, which, if watered and ſhaded, will take root very well, and may afterwards be tranſplanted where they are deſigned to remain.

The ſecond ſort is alſo a native of the country about the Cape of Good Hope, from whence it was brought to Europe; this riſes with round, ſoft, ligneous ſtalks five or ſix feet high, which ſend out two or three branches from their ſide, garniſhed with winged leaves like thoſe of the former ſort, but not half ſo large; theſe have two diſtinct ſtipulæ adhering to their foot-ſtalks; they are of a deep green on their upper ſide, and whitiſh on their under. The flowers come out from the ſide of the ſtalks in looſe hanging panicles, each ſuſtaining ſix or eight flowers, which are ſhaped like thoſe of the firſt ſort, but ſmaller; the lower part of the petals are green, their upper part are of a Saffron colour, and on the outſide, in the ſwelling part of the petals, is a bluſh of fine red; theſe have two long and two ſhorter ſtamina, which are terminated by yellow ſummits. The flowers are ſucceeded by four-cornered ſeed-veſſels, which are ſhorter than thoſe of the firſt ſort, in which are lodged four oval ſeeds in ſeparate apartments; this flowers at the ſame ſeaſon with the former.

This ſort does not ſpread its roots as the firſt, ſo is not propagated with ſo great facility, but cuttings of this ſort planted upon an old hot-bed, whoſe heat is over, and covered cloſe with bell or hand-glaſſes to exclude the air, will take root pretty freely; theſe may be planted in pots, and ſheltered in the winter under a common frame for a year or two till they have obtained ſtrength, then they may be planted in a warm border, and treated in the ſame way as the former ſort, with which management I have ſeen them flower much better than any of thoſe which have been treated more tenderly, and theſe plants have perfected their ſeeds in good ſeaſons.

MELICOCCA. See Sapindus.

MELILOTUS. See Trigonella.

MELISSA. Tourn. Inſt. R. H. 193. tab. 91. Lin. Gen. Plant. 647. [ſo called of μέλι, honey, becauſe the bees procure it from this plant; it is alſo called Meliſſophyllon, μέλι, and φύλλον, a leaf, q. d. Honey Leaf.] Baum.

The Characters are,

The empalement of the flower is of the open, bell-ſhape, angular kind, ſtreaked with one leaf, whoſe brim is formed into two lips; the upper lip is indented in three parts, which are ſpread open and reflexed; the under lip is ſhort, acute, and indented in two parts. The flower is of the lip kind, having a cylindrical tube; the chaps are gaping, the upper lip is ſhort, erect, forked, and roundiſh, indented at the end. The under lip is trifid, the middle part being the largeſt. It hath four awl-ſhaped ſtamina, two of which are as long as the petal, but the other are but half ſo long; they are terminated by ſmall ſummits, which join by pairs. It hath a quadrifid germen, ſupporting a ſlender ſtyle the length of the petal, which, with the ſtamina, are ſituated under the upper lip, and is crowned by a ſlender, bifid, reflexed ſtigma. The germen afterward turns to four naked ſeeds, ſitting in the empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's fourteenth claſs, which includes the plants whoſe flowers have two long and two ſhort ſtamina, whoſe ſeeds are naked.

The Species are,

1. Melissa (*Officinalis*) racemis axillaribus verticillatis, pedicellis ſimplicibus. Lin. Sp. Plant. 592. *Baum with whorled bunches of flowers proceeding from the ſides of the ſtalks, having ſingle foot-ſtalks.* Meliſſa hortenſis. C. B. P. 229. *Garden Baum, or common Baum.*
2. Melissa (*Romana*) floribus verticillatis ſeſſilibus, foliis hirſutis. *Baum with whorls of flowers ſitting cloſe to the ſtalks, and hairy leaves.* Meliſſa Romana, molliter hirſuta & graveolens. H. R. Par. *Roman Baum with ſoft hairy leaves, and a ſtrong ſmell.*
3. Melissa (*Grandiflora*) pedunculis axillaribus dichotomis longitudine florum. Lin. Sp. Plant. 592. *Baum with foot-ſtalks ariſing from the wings of the ſtalk, which are divided in forks, and are the length of the flowers.* Calamintha magno flore. C. B. P. 229. *Calaminth with a large flower.*
4. Melissa (*Calamintha*) pedunculis axillaribus dichotomis longitudine foliorum. Lin. Sp. Plant. 593. *Baum with foot-ſtalks ariſing from the wings of the ſtalk, which are forked, and as long as the leaves.* Calamintha vulgaris & officinarum Germaniæ. C. B. P. 228. *Common officinal Calamint of the Germans.*
5. Melissa (*Nepeta*) pedunculis axillaribus dichotomis folio longioribus, caule decumbente. Lin. Sp. Plant. 593. *Baum with foot-ſtalks ariſing from the wings of the ſtalk, which are forked, and longer than the leaves, with a declining ſtalk.* Calamintha pulegii odore ſive nepeta. C. B. P. 228. *Calamint with the ſcent of Penny Royal, or Cat Mint.*
6. Melissa (*Cretica*) racemis terminalibus, pedunculis ſolitariis breviſſimis. Lin. Sp. Plant. 593. *Baum with ſpikes of flowers terminating the ſtalks, growing upon very ſhort ſingle foot-ſtalks.* Calamintha incana ocymi foliis. C. B. P. 228. *Hoary Calamint with Baſil leaves.*
7. Melissa (*Majoranifolia*) foliis ovatis glabris, floribus verticillatis ſeſſilibus, pedunculis ſolitariis breviſſimis. *Baum with oval ſmooth leaves, and flowers growing in whorls, ſitting cloſe to the branches, which have very ſhort ſingle ſtalks.* Calamintha Romana, majoranæ

folio, pulegii odore. Bocc. Muſ. *Roman Calamint with a Marjoram leaf, and the ſcent of Penny Royal.*

8. Melissa (*Fruticoſa*) fruticoſa, ramis attenuatis virgatis, foliis ſubtus tomentoſis. Lin. Sp. Plant. 593. *Shrubby Baum with ſlender twig-like branches, and leaves which are woolly on their under ſide.* Calamintha Hiſpanica fruteſcens, mari folio. Tourn. Inſt. 194. *Shrubby Spaniſh Calamint with a Marum leaf.*

The firſt ſort grows naturally on the mountains near Geneva, and in ſome parts of Italy, but is cultivated here in gardens as a medicinal and culinary herb. It has a perennial root, and an annual ſtalk, which is ſquare, branching, and riſes from two to three feet high, garniſhed with leaves ſet by pairs at each joint, which are two inches and a half long, and almoſt two inches broad at their baſe, growing narrower toward the top, indented about their edges, and the lower ones ſtanding upon pretty long foot-ſtalks. The flowers grow in looſe ſmall bunches at the wings of the ſtalk, in whorls, ſtanding upon ſingle foot-ſtalks; they are of the lip kind, the upper lip ſtanding erect and is forked; the under lip is divided into three parts; the middle one is roundiſh, and indented at the top. The flowers are white, and appear in July. The whole plant has a pleaſant ſcent, ſomewhat like Lemons.

It is reckoned to be cordial, cephalic, and good for all diſorders of the head and nerves; there is a ſimple water of this herb. It is alſo uſed as Tea, and is by ſome greatly eſteemed for that purpoſe; there is a variety of this with ſtriped leaves.

This plant is eaſily propagated by parting of the root; the beſt time for this is in October, that the offſets may have time to get root before the froſts come on. The roots may be divided into ſmall pieces with three or four buds to each, and planted two feet apart in beds of common garden earth, in which they will ſoon ſpread and meet together; the only culture it requires is to keep it clean from weeds, and cut off the decayed ſtalks in autumn, ſtirring the ground between the plants.

The ſecond ſort grows naturally about Rome, and in ſeveral parts of Italy; this hath a perennial root, and an annual ſtalk like the former. The ſtalks are ſlender, the leaves are much ſhorter than thoſe of the former ſort, and the whole plant is hairy, and of a ſtrong diſagreeable odour. The flowers grow in whorls, ſitting pretty cloſe to the branches, and are ſmaller than thoſe of the firſt ſort; it flowers about the ſame time. It is ſeldom preſerved in gardens, but may be cultivated in the ſame way as the former.

The third ſort grows naturally in the mountains of Tuſcany and Auſtria, but is preſerved in many Engliſh gardens for the ſake of variety. It hath a perennial root, and an annual ſtalk, which riſes about a foot high, garniſhed at each joint with two leaves ſtanding oppoſite, which are an inch and a half long, and three quarters of an inch broad, ſawed on their edges, of a lucid green on their upper ſide, and whitiſh on their under: from the wings of the ſtalks come out ſingle foot-ſtalks half an inch long, which divide into two ſmaller, and each of theſe ſuſtain two flowers upon ſhort ſeparate foot-ſtalks. The flowers are large, of a purple colour, and ſhaped like thoſe of the other ſpecies. It flowers in June, and the ſeeds ripen in Auguſt. This may be propagated in the ſame way as the firſt ſort, and the plants may be treated in the ſame manner.

The fourth ſort is the common Calamint of the ſhops, which grows naturally in many parts of England, ſo is ſeldom kept in gardens. It hath a perennial root, from which ariſe ſeveral ſquare ſtalks near a foot long, which are hairy, and garniſhed with two roundiſh leaves at each joint, about the ſize of thoſe of Pot Marjoram, a little indented on their edges, and of a ſtrong penetrating odour. The flowers come out in whorls on the ſide of the ſtalks, upon foot-ſtalks, which divide by pairs, and are as long as the leaves; theſe ſuſtain ſeveral ſmall bluiſh flowers, which appear in July, and are ſucceeded each by four ſmall, roundiſh, black ſeeds. The herb is uſed in medicine, and is hotter, and abounds with more ſubtile and volatile parts than Mint. It provokes urine, brings down the menſes, opens the liver, and is good for coughs. This may be planted in gardens, and treated in the ſame way as the common Baum.

The fifth ſort is found in greater plenty than the fourth, growing wild in England. The ſtalks of this are longer and bend towards the ground. The leaves are larger, and more indented on their edges, and have a very ſtrong ſcent like Penny Royal. The whorls of flowers are ſet cloſer together than thoſe of the fourth ſort, but in other reſpects they agree.

The ſixth ſort grows naturally in the ſouth of France and in Italy; this is not of ſo long duration as the former ſorts, ſeldom continuing more than two or three years. The ſtalks are ſlender, a little ligneous, and are garniſhed with ſmall, roundiſh, hoary leaves, placed oppoſite at each joint. The flowers are produced in whorls toward the upper part of the ſtalks, which are terminated by a looſe ſpike; they are ſmall and white, ſhaped like thoſe of the other ſpecies, and appear in June; theſe are ſucceeded by ſeeds, which ripen in autumn, and if they are permitted to ſcatter, there will be a ſufficient ſupply of young plants.

The ſeventh ſort grows naturally in Italy; this is a biennial plant, whoſe ſtalks are about eight inches long, declining toward the ground, and are garniſhed with roundiſh leaves about the ſize of Marjoram, of a light green colour. The flowers come out in cloſe whorls on the upper part of the ſtalks, each ſtanding upon a ſhort ſeparate foot-ſtalk; they are large, and of a bright purple colour, appearing in July and Auguſt, and the ſeeds ripen in autumn; this is propagated by ſeeds, which ſhould be ſown ſoon after they are ripe, and then the plants will come up in the ſpring; but when the ſeeds are not ſown till the ſpring, they ſeldom grow till the next year. The plants may alſo be propagated by cuttings, which if planted in the ſummer, and ſhaded from the ſun, will take root very freely. If theſe plants are on a warm border, they will live through the winter, but to preſerve the ſpecies, a plant or two ſhould be kept in pots, and ſheltered under a frame in winter.

The eighth ſort grows naturally in Spain; this hath ſlender ſhrubby ſtalks about nine inches long, which put out ſmall ſide branches oppoſite, and are garniſhed with ſmall, hoary, oval-pointed leaves, placed by pairs; theſe have much the appearance of thoſe of the Marum. The flowers grow in whorled ſpikes, at the end of the ſtalks; they are ſmall and white, appearing in July, and the ſeeds ripen in autumn. The whole plant has a ſtrong ſcent of Penny Royal; this plant is of as ſhort a duration as the ſeventh ſort, and may be propagated either by ſeeds or cuttings in the ſame way as the ſeventh, and the plants require the ſame treatment.

MELISSA TURCICA. See Dracocephalon.

MELITTIS. Greater Dead Nettle.

The Characters are,

It hath an erect, taper, bell-ſhaped empalement, having two lips; the upper is tall and indented, the under is ſhort and bifid; the flower is ringent, the tube is longer than the empalement, the chaps are thicker; the upper lip is roundiſh, plain, and erect; the lower is trifid, ſpreading, and obtuſe. It hath four ſtamina, which are awl-ſhaped, ſituated under the upper lip, two being a little longer than the other, terminated by bifid obtuſe ſummits, which are placed a croſs; it hath an obtuſe, quadrifid, hairy germen ſupporting a ſlender ſtyle, crowned by a bifid acute ſtigma. The flower is ſucceeded by four ſeeds which ripen in the empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's fourteenth claſs, intitled Didynamia Gymnoſpermia, the flowers having two long and two ſhort ſtamina, and are ſucceeded by four naked ſeeds ſitting in the empalement.

We know but one Species of this genus, viz.

Melittis (*Melyſſophyllum.*) Hort. Cliff. 309. *Greater Dead Nettle.* Meliſſa. Fuchſii.

This plant grows naturally in ſome woods in the Weſt of England and in Wales, Germany and near Montpelier. It hath a perennial root, which in the ſpring ſends up three, four, or more ſtalks, according to the age and ſtrength, which riſe a foot and a half high; theſe are ſquare, and garniſhed with leaves like thoſe of the common Dead Nettle, but are much larger, rougher, and ſtand on longer foot-ſtalks, two being placed oppoſite at each joint. The flowers come out at the joints of the ſtalks, juſt above the foot-ſtalks of the leaves; they are in ſhape like thoſe of the Dead Nettle, but are much larger, of a redder purple colour, and the upper lip grows erect. Theſe appear in May, when the plants make a handſome appearance, and if the ſeaſon does not prove hot, the flowers will continue in beauty upward of three weeks. As the plants do rarely produce good ſeeds in the gardens, ſo they are uſually propagated by parting the roots; but where the plants are intended for ornament, the roots ſhould not be diſturbed oftener than every third year; nor ſhould they then be divided into ſmall parts, leſt thereby they ſhould not flower the firſt year. The beſt time to remove and part the roots is the beginning of October, that they may have time to get root before the froſt comes on. They ſhould have a loamy ſoil and an eaſt expoſure, where the plants will thrive and produce flowers in plenty.

MELO. Tourn. Inſt. R. H. 104. tab. 32. Cucumis. Lin. Gen. Plant. 969. [it takes its name of Μῆλον, an Apple, becauſe the fruit reſembles an Apple.] The Melon.

The Characters are,

It hath male and female flowers on the ſame plant. The male flowers have a bell-ſhaped empalement of one leaf, whoſe border is terminated by five awl-ſhaped briſtles. The flower is of one petal, which is bell-ſhaped, faſtened to the empalement, and cut into five ſegments at the brim; theſe are veined and rough. It hath three ſhort ſtamina inſerted in the empalement, and are joined together, two of which have bifid points. The ſummits are linear, and run up and down on the outſide of the ſtamina, to which they adhere. The female flowers have no ſtamina or ſummits, but have a large oval germen ſituated below the flower, ſupporting a ſhort cylindrical ſtyle, crowned by three thick gibbous ſtigmas. The germen afterward turns to an oval fruit with ſeveral cells, filled with oval, acute-pointed, compreſſed ſeeds, incloſed in a ſoft pulp.

This genus of plants is by Dr. Linnæus joined with the Colocynthus and Anguria, to the Cucumis, making them only ſpecies of the ſame genus, which, according to his ſyſtem, may be allowable; but whoever will admit the fruit as a characteriſtic note to diſtinguiſh the genera, will find marks to ſeparate them; and however properly theſe may be put together in a ſyſtem of botany, yet in a work of this nature it cannot be admitted.

There is a great variety of this fruit cultivated in the different parts of the world, and in this country there are too many of them propagated, which are of no value, eſpecially by thoſe who ſupply the markets, where their ſize is chiefly regarded; ſo that by endeavouring to augment their bulk, the fruit is rendered of no value; I ſhall therefore only mention a very few of the varieties, which are the moſt deſerving of care, excluding the common Melons, as being unworthy of the trouble and expence in cultivating.

The ſort of Melon which is in the greateſt eſteem among all the curious in every part of Europe, is the Cantaleupe; which is ſo called from a place about fourteen miles from Rome, where the pope has a country ſeat, in which place this fruit has been long cultivated; but it was brought thither from that part of Armenia which borders on Perſia, where this fruit is in ſo great plenty, that a horſe-load is ſold for a French crown. The fleſh of this Melon, when in perfection, is delicious, and does not offend the moſt tender ſtomachs, ſo may be eaten with ſafety. The Dutch are ſo fond of this fruit, as to cultivate very few other ſorts, and by way of pre-eminence, call it only by the appellation of Cantaleupe, and never join the title of Melon to it, which they apply indifferently to all the other ſorts. The outer coat of this is very rough, and full of knobs and protuberances like warts; it is of a middling ſize, rather round than long, and the fleſh is for the moſt part of an Orange colour, though there are ſome with a greeniſh fleſh, but I have never met with any of that colour ſo good as thoſe of the other.

The Romana is by ſome much eſteemed, and when the fruit is well conditioned, the plants in perfect health, and the ſeaſon dry, it is a good Melon, and may be brought forwarder in the ſeaſon than the Cantaleupe; therefore thoſe who are deſirous of early Melons may cultivate this ſort.

The Succado is alſo a good ſort, and may alſo be cultivated for early fruit, but theſe muſt give way to the Cantaleupe, when that is in ſeaſon.

The Zatte is alſo a very good Melon, but very ſmall. The fruit of this is ſeldom bigger than a large Orange; it is a little flatted at the two ends, and the outer coat is warted like the Cantaleupe, but there is ſo little fleſh in one of theſe fruit, that they are ſcarce worthy the trouble of propagating.

The ſmall Portugal Melon, which is by ſome called the Dormer Melon, is a pretty good fruit, and the plants generally produce them in plenty, ſo by many people this is preferred to moſt other, eſpecially thoſe who love a plenty, and are not ſo nice in diſtinguiſhing the quality: this may alſo be cultivated for an early crop.

But the beſt Melon for this purpoſe is the Black Galloway, which was brought from Portugal by Lord Galloway many years ſince, but of late years is rarely to be met with in England, it having been degenerated by growing among other ſorts. The fruit of this ſort will ripen in a ſhorter time from its firſt ſetting, than any other which I have yet ſeen, and when ſuffered to ripen naturally, is not a bad fruit.

The few varieties here mentioned, are ſufficient to ſatisfy the curious, who may be fond of variety, for there are ſcarce any other which deſerve the trouble; and indeed thoſe who have a true taſte for this fruit, ſeldom cultivate any but the Cantaleupe; but as I before obſerved, where this fruit is deſired early in the ſeaſon, the Cantaleupe is not ſo proper as ſome of the other, therefore a few plants of one of the other ſorts ſhould be raiſed earlier in the ſpring, but ſhould be in a different part of the garden from the Cantaleupe Melons; for when two ſorts of Melons grow near, they cannot be preſerved perfectly right; therefore the Dutch and German gardeners are very careful in this reſpect, and in order to keep the ſort in perfection, do not plant any other ſort of Melon, Cucumber or Gourd, near theſe, leſt, by the impregnation of the farina of thoſe other, theſe fruit ſhould be rendered bad; and in this particular, I am convinced, from long experience, they are right; and from the not obſerving this, many perſons who are lovers of this fruit, have gradually diminiſhed their goodneſs, without knowing the cauſe, and have imputed it to the long cultivating from the ſeeds ſaved in the ſame garden, believing it abſolutely neceſſary to procure ſeeds from a diſtant place frequently to preſerve them good: indeed, where a perſon can ſecurely depend on the care and ſkill of thoſe he procures the ſeeds from, it is a very good method to exchange ſeeds now and then; but there are ſo few who are exact in making choice of the fruits from which they ſave the ſeeds, or careful enough to do it themſelves, but often depend on others to clean the ſeed, that I ſhould adviſe every one to do it himſelf, which is the ſure way to have it good; for I have frequently been deceived myſelf, by depending on the fidelity and ſkill of others; nor could I procure any of theſe ſeeds from Cantaleupe which were good, until my much honoured friend, the Chevalier Rathgeb, ſent me plentifully of it from thence; though I had often been ſupplied with ſeeds by perſons who I thought could not be deceived in their choice, and who lived near the place of their growth.

Before I quit this head, I beg leave to caution all perſons againſt depending upon ſeeds which are brought from abroad, either by thoſe perſons who import them for ſale, or gentlemen who frequently bring or ſend over theſe ſeeds to their friends, for it ſeldom happens that any of theſe prove tolerable. I have been ſo often deceived by theſe myſelf, as to determine never to make trial of any of theſe ſeeds again, unleſs I receive them from a perſon who is ſkilful, and who eat of the fruit himſelf of which he ſaved the ſeeds; for in Italy, Spain, Portugal, and many parts of France, the gardeners are very careleſs in the choice of all their ſeeds, but of the Melons they are remarkably ſo; and as for thoſe which come from Conſtantinople, Aleppo, and other parts of Turkey, I have rarely ſeen one Melon produced from thoſe ſeeds which was tolerable.

The ſeeds of Melons ſhould not be ſown until they are three years old, nor would I chuſe to ſow them when they are more than ſix; for although they will grow at ten or twelve years old, yet the fruit which are produced from thoſe old ſeeds are ſeldom ſo thick fleſhed, as thoſe which come from ſeeds which are freſher: and it is the ſame of light ſeeds, which ſwim upon water, when they are taken out of the pulp, for I have made ſome trials of theſe, and have had them grow at three years old; but not one of the Melons produced on theſe plants was near ſo deep fleſhed, as thoſe which grew upon plants raiſed from heavy ſeeds taken out of the ſame fruit, though they grew in the ſame bed, and were cultivated exactly in the ſame manner; nor was their fleſh ſo firm, but rather inclining to be meally; therefore I would not adviſe the ſowing of theſe light ſeeds, nor thoſe which are very old.

Having thus largely treated of the choice of the ſorts, and of the ſeeds, I ſhall next proceed to the method of cultivating them, in order to obtain plenty of good fruit: the method which I am going to preſcribe being very different from what has been conſtantly practiſed in England, will, I doubt not, be objected to by many; but it is what has been practiſed in all the good gardens in Holland and Germany, where the Cantaleupe Melon is produced in great plenty and perfection; and from ſeveral years experience, I have found this to be the only method in which theſe Melons can be cultivated with ſucceſs; and I am likewiſe convinced of its being the beſt way to obtain plenty of any other ſort of Melon.

It is common to hear many perſons valuing themſelves upon having two or three early Melons, which, when brought to the table are not better than a Pumpkin, and theſe are procured at a great expence and with much trouble; and in order to have them ripe a little earlier than they would naturally come, if ſuffered to grow to their full ſize, the ſtem upon which the fruit grows is commonly twiſted, to prevent the nouriſhment entering the fruit, whereby the growth is checked; then the fruit is cloſely covered with the mowings of Graſs-plats, laid of a ſufficient depth to cauſe a fermentation, by which the fruit becomes coloured: but where this unnatural method is practiſed, the fruit has little fleſh, and that has neither moiſture, firmneſs, or flavour; ſo that after four months attendance, with a great expence of dung, &c. there may, perhaps, be three or four brace of Melons produced, which are fitter for the dunghill than the table. Therefore my advice is, never to attempt to have theſe fruit ripe earlier than the middle or latter end of June, which is generally ſoon enough for this climate; and from that time to the end of September, they may be had in plenty, if they are ſkilfully managed; and when the autumn has continued favourable, I have had them very good in the middle of October.

But in order to continue this fruit ſo long, the ſeeds muſt be ſown at two or three different ſeaſons: the firſt ſhould be ſown about the middle or end of February, if the ſeaſon proves forward; but if it is otherwiſe, it will be better to defer it till the end of that month; the future ſucceſs greatly depends on the raiſing the plants in ſtrength, which cannot be ſo well effected, if the weather ſhould prove ſo bad after the plants are come up, as that a ſufficient quantity of freſh air cannot be admitted to them, therefore it is not adviſeable to be too early in ſowing the ſeeds.

When the ſeaſon is come, theſe ſeeds may be ſown on the upper ſide of a Cucumber-bed, where there are any; and if there are none, a proper quantity of new horſe dung muſt be provided, which muſt be thrown in a heap to ferment, and turned over, that it may acquire an equal heat, in the ſame manner as hath been directed for Cucumbers; and the plants muſt be raiſed and managed in the ſame manner as hath been directed for them, until they are planted where they are to remain for good, to which article the reader is deſired to turn, to avoid repetition.

The ſecond ſeaſon for ſowing of theſe ſeeds is about the middle of March, and both theſe ſowings muſt be underſtood to be planted under frames; for thoſe which are deſigned for bell or hand-glaſſes, or to be covered with oil papers, ſhould not be ſown till about a week in April; for when theſe are ſown earlier, if the plants are properly managed, they will grow ſo long, as to extend their ſhoots to the ſides of the glaſſes, before it will be ſafe to let them run out; for it often happens in this country, that we have ſharp morning froſts in the middle of May; ſo that if the ends of theſe Vines are then without the glaſſes, if they are not covered with mats to guard them againſt the froſt, they will be in danger of ſuffering greatly therefrom; and, on the other hand, if the plants have ſpread ſo much as to fill the glaſſes, and not permitted to run out, they will be in equal danger of ſuffering by their confinement from the heat of the ſun in the day time; therefore it is that I ſhould adviſe the putting of the ſeed rather a little later into the hot-bed for the glaſſes, than thoſe which are to be covered with the oil papers. Nor will the times here mentioned be found too late, for I have put the ſeeds of Cantaleupe Melons into a hot-bed the third of May, which were not tranſplanted, but remained where they were ſown, and covered with oiled paper; and from this bed I cut a large crop of good fruit, which ripened about the latter end of Auguſt, and continued till the end of October. This I only mention, to ſhew what has and may be done, though it muſt not be always depended on.

But we next come to the making and preparing of the beds, or, as the gardeners term it, the ridges, into which the plants are to be put out to remain; theſe ſhould always be placed in a warm ſituation, where they may be defended from all cold and ſtrong winds, for the eaſt and north winds are generally very troubleſome in the ſpring of the year; ſo that if the place be expoſed to thoſe aſpects, it will be difficult to admit a proper ſhare of freſh air to the young plants; and if it is much expoſed to the ſouth-weſt winds, which often are very boiſterous in ſummer and autumn, theſe will turn up and diſplace the Vines, whereby they will ſuffer greatly; therefore the beſt poſition for theſe beds is where they are open to the ſouth, or a little inclined to the eaſt, and ſheltered at a diſtance by trees from the other points: this place ſhould be incloſed with a good Reed fence, which is better for this purpoſe than any other incloſure, becauſe the winds are deadened by the Reeds, and are not reverberated back again, as they are by walls, pales, and other cloſe fences; but in making the incloſure, it ſhould be extended to ſuch diſtance every way from the beds, as not to obſtruct the ſun's rays during any part of the day; this ſhould have a door wide enough to admit of wheelbarrows paſſing, to carry in dung, earth, &c. and it ſhould be kept locked, that no perſons ſhould be allowed to go in but thoſe who have buſineſs; for ignorant perſons, having often curioſity to look into the beds, open the glaſſes and let the cold air to the plants, and frequently leave the glaſſes in part open; or ſometimes when they are raiſed by the gardener to admit the freſh air, the tilts are thrown down, ſo that the air is excluded; all which are very injurious to the young plants, as is alſo the handling of the fruit after it is ſet; therefore none ſhould be admitted, but when the perſon who is intruſted with the care of them is there.

The next thing is the preparation of the earth for theſe plants, in which the Dutch and German gardeners are very exact: the mixture which they generally prepare is of the following ſorts; of hazel loam, one third part; of the ſcouring of ditches or ponds a third part, and of very rotten dung a third part; theſe are mixed up at leaſt one, and often two years, before they make uſe of it, frequently turning it over, to incorporate their parts and ſweeten it; but the compoſt in which I find theſe plants ſucceed beſt in England, is two thirds of freſh gentle loam, and one third of rotten neats dung; if theſe are mixed together one year before it is wanted, ſo as to have the benefit of a winter's froſt and ſummer's heat, obſerving to turn it over often, and never ſuffer weeds to grow upon it, this will be found equal to any other compoſt whatever.

As theſe plants ſucceed beſt when they are planted young, ſo before the plants appear there ſhould be a quantity of new dung thrown in a heap, proportionable to the number of lights intended, allowing about fifteen good wheelbarrows full to each light; this muſt be two or three times turned over, to prepare it (as hath been directed for Cucumbers) and in a fortnight it will be fit for uſe, at which time the trench muſt be dug to receive the dung, where the bed is intended; this muſt be made wider than the frames, and in length proportional to the number of frames intended. As to the depth, that muſt be according as the ſoil is dry or wet; but in a dry ground it ſhould not be leſs than a foot, or a foot and a half deep; for the lower theſe beds are made the better they will ſucceed, where there is no danger of their ſuffering by wet. In the well laying and mixing of the dung, the ſame care muſt be taken as hath been adviſed already for Cucumbers, which in every reſpect muſt be the ſame for theſe beds. When the bed is made, the frames ſhould be placed over it to keep out wet; but there ſhould be no earth laid upon it till after it has been three or four days made, and is found of a proper temperature of heat; for many times theſe beds will heat ſo violently when they are firſt made, as to burn the earth, if covered with it; and when this happens, it is much the beſt way to take this earth off again, for the plants will never thrive in it. As ſoon as the bed is found to be of a proper warmth, the earth ſhould be laid upon it, which at firſt need not be more than two inches thick, except in the middle of each light, where the plants are to be placed, where there muſt be a hill raiſed fifteen inches high or more, terminating in a flat cone; in two or three days after the earth is put on the bed, it will be of a proper temper to receive the plants; then in the evening you may tranſplant the plants, but always do it when there is little wind ſtirring: in taking up the plants, their roots ſhould be carefully raiſed with a trowel, ſo as to preſerve all their fibres; for if theſe are broken off, the plants do not ſoon recover this; or if they do, they are generally weaker, and ſeldom make ſo good Vines as thoſe which are more carefully removed; for theſe plants are more nice and tender in tranſplanting than thoſe of Cucumber, eſpecially the Cantaleupe Melon; which, if it is not planted out, ſoon after the third, (or what the gardeners call the rough) leaf is put out, they are long recovering their vigour; ſo that when it happens that the beds cannot be ready for them in time, it will be a good method to plant each plant into a ſmall pot while they are young, and theſe may be plunged into the hot-bed where they were raiſed, or into the Cucumber-bed where there is room, ſo that they may be brought forward; and when the bed is ready, theſe may be turned out of the pots, with the whole ball of earth to their roots, whereby they will receive no check in removing: and this latter method is what I ſhould prefer to any other for the Cantaleupe, becauſe there ſhould never be more than one plant left to grow in each light; therefore in this method there will be no neceſſity of planting more, as there will be no danger of their ſucceeding; whereas in the common way, moſt people plant two or more plants in each light, for fear ſome ſhould miſcarry. When the plants are placed on the top of the hills, they ſhould be gently watered, which ſhould be repeated once or twice after till the plants have taken good root, after which they ſeldom require more; for when they receive too much wet, they often canker at the root, and when that happens they never produce good fruit. When the plants have eſtabliſhed themſelves well in the new beds, there ſhould be a greater quantity of earth laid on the bed, beginning round the hills where the plants grow, that their roots may have room to ſtrike out; and as the earth is put in from time to time, it muſt be trodden or preſſed down as cloſe as poſſible; and it ſhould be raiſed at leaſt a foot and a half thick upon the dung all over the bed, obſerving alſo to raiſe the frames, that the glaſſes may not be too near the plants, leſt the ſun ſhould ſcorch them.

When the plants have gotton four leaves, the top of the plants ſhould be pinched off with the finger and thumb, but not bruiſed or cut with a knife, becauſe in either of theſe caſes the wound will not ſo ſoon heal over: this pinching is to cauſe the plants to put out lateral branches, for theſe are what will produce the fruit; therefore, when there are two or more of theſe lateral ſhoots produced, they muſt alſo be pinched, to force out more; and this muſt be practiſed often, that there may be a ſupply of what the gardeners call runners, to cover the bed. The management of theſe beds muſt be nearly the ſame as hath been directed for the Cucumbers, therefore I need not repeat it here; but ſhall only obſerve, that the Melons require a greater ſhare of air than Cucumbers, and very little water; and when it is given to them, it ſhould be at a diſtance from their ſtems.

If the plants have ſucceeded well, they will ſpread over the bed, and reach to the frames, in about five or ſix weeks, at which time the alleys between the beds ſhould be dug out; or where there is but one bed, there ſhould be a trench made on each ſide, of about four feet wide, as low as the bottom of the bed, and hot dung wheeled in, to raiſe a lining to the ſame height as the dung of the bed, which ſhould be trodden down cloſe, and afterward covered with the ſame earth as was laid upon the bed, to the thickneſs of a foot and a half or more, treading it down as cloſe as poſſible; this will add to the width of the bed, ſo much as to make it in the whole twelve feet broad, which is abſolutely neceſſary, for the roots of the plants will extend themſelves quite through it; and it is for want of this precaution, that it is common to ſee the Vines of Melons decay, before the fruit is well grown; for where there is no addition made to the width of the bed, the roots will have reached the ſides of the beds by the time that the fruit appears, and having no more room to extend themſelves, their extremities are dried by the ſun and air, which is ſoon diſcovered by the plants hanging their leaves in the heat of the day, which is ſoon attended with a decay of many of thoſe leaves which are near the ſtem, and the plants from that time gradually languiſh, ſo that the fruit cannot be ſupplied with nouriſhment; but when ripe, will be found to have little fleſh, and that meally and ill flavoured; whereas thoſe plants which have ſufficient breadth for their roots to run, and the earth laid of a proper depth and cloſely trod down, will remain in vigour until the froſt deſtroys them, ſo that I have had a ſecond crop of fruit on them, which have ſometimes ripened well; but all the firſt were excellent, and of a larger ſize than theſe ſorts uſually grow: the leaves of theſe plants were very large, and of a ſtrong green, ſo that they were in the utmoſt vigour; whereas, in moſt places where the Cantaleupe Melons have been raiſed in England, the beds have been no wider than they were firſt made, and perhaps not more than three inches thickneſs of earth upon them, ſo that the plants have decayed many times without producing a ſingle fruit; and from thence people have imagined, that this ſort of Melon was too tender for this climate, when their ill ſucceſs was entirely owing to their not underſtanding their culture.

There is alſo another advantage attending this method of widening the beds, as above directed, which is that of adding a freſh warmth to the beds, by the hot dung, which is buried on each ſide, which will cauſe the dung in the bed to renew its heat; and as the plants will by this time ſhew their fruit, this additional heat will be of great ſervice in ſetting the fruit, eſpecially if the ſeaſon ſhould prove cold, as it often happens in this country in the month of May. When the beds are made up in the manner here directed, and the Vines have extended ſo far as to fill the frames, and want more room, the frames ſhould be raiſed up with bricks about three inches high, to admit the ſhoots of the Vines to run from under them; for if the plants are ſtrong, they will run ſix or ſeven feet each way from the ſtems; for which reaſon, I caution every one to allow them room, and to put but one plant in each light; for when the Vines are crowded, the fruit ſeldom will ſet well, but will drop off when they are as large as an egg; therefore the frames which are deſigned for Melons ſhould not be made ſmall, but rather ſix feet wide; for the wider theſe are, the better will the plants thrive, and produce a greater plenty of fruit.

There is no part of gardening, in which the practitioners of this art differ more than in the pruning and managing of theſe plants: nor are there any rules laid down in the ſeveral books in which the culture of Melons have been treated of, by which any perſon can be inſtructed; for there is ſuch inconſiſtency in all their directions, and what is worſe, the greateſt part of them are abſurd, ſo that whoever follows them can never hope to ſucceed; therefore I ſhall, in as few words as poſſible, give ſuch plain directions, as I hope will be ſufficient to inſtruct any perſon, who is the leaſt converſant in theſe things.

I have before adviſed the pinching off the ends of the plants as ſoon as they have a joint, in order to get lateral ſhoots, which are by the gardeners called runners; and when theſe ſhoots have two or three joints, to pinch off their tops to force out more runners, becauſe it is from theſe that the fruit is to be produced; but after a ſufficient number are put out, they ſhould not be ſtopped again, but wait for the appearance of the fruit, which will ſoon come out in plenty; at which time the Vines ſhould be carefully looked over three times a week, to obſerve the fruit, and make choice of one upon each runner, which is ſituated neareſt the ſtem, having the largeſt foot-ſtalk, and that appears to be the ſtrongeſt fruit, and then pinch off all the other fruit which may appear on the ſame runner; alſo pinch off the end of the runner at the third joint above the fruit, and if the runner is gently pinched at the next joint above the fruit, it will ſtop the ſap and ſet the fruit. There is alſo another method practiſed by ſome gardeners to ſet this fruit, which is the taking off ſome of the male flowers, whoſe farina are juſt ripe and fit for the purpoſe, laying them over the female flowers, which are ſituated on the crown of the young fruit, and with their nails gently ſtrike the male flowers to ſhake the farina into the female flowers, whereby they are impregnated, and the fruit ſoon after will ſwell, and ſhew viſible ſigns of their being perfectly ſet; ſo that where the plants are under frames, and the wind excluded from them, which is neceſſary to convey the farina from the male to the female flowers, this practice may be very neceſſary. The taking off all the other fruit will prevent the nouriſhment being drawn away from the fruit intended to grow, which, if they were all left on the plant, could not be ſupplied with ſufficient nouriſhment; ſo that when they come to be as large as the end of a man's thumb, they frequently drop off, and ſcarce one of them ſets, which will be prevented by the method before directed: but there are ſome perſons, who are ſo covetous of having a number of fruit, as hot to ſuffer any to be taken off, whereby they generally fail in their expectation. My allowing but one fruit to be left upon each runner is, becauſe if half theſe ſtand there will be full as many fruit as the plant can nouriſh; for if there are more than eight upon one plant, the fruit will be ſmall and not ſo well nouriſhed: indeed, I have ſometimes ſeen fifteen or twenty Melons upon one plant, but theſe have generally been of the ſmaller kinds, which do not require ſo much nouriſhment as the Cantaleupes, whoſe ſkins are of a thick ſubſtance; ſo that where a greater number are left of them than the plants can well ſupply, their fleſh will be remarkably thin.

As I before adviſed the ſtopping or pinching off the runners three joints above the fruit, ſo by this there will be freſh runners produced a little below the places where the others were pinched; therefore it is, that I adviſe the careful looking over the Vines ſo often, to ſtop theſe new runners ſoon after they come out, as alſo to pull off the young fruit which will appear; and this muſt be repeated as often as is found neceſſary, which will be until thoſe intended to ſtand are grown ſo large as to draw all the nouriſhment which the plants can ſupply, for then the plants will begin to abate of their vigour. Theſe few directions, if properly made uſe of, is all the pruning which is neceſſary to be given them; but at the ſame time when this is practiſed, it may be neceſſary to give ſome water to the plants, but at a diſtance from their ſtems, which will be of ſervice to ſet the fruit and cauſe it to ſwell, but this muſt be done with great caution.

The glaſſes of the hot-bed ſhould alſo be raiſed high, to admit a large ſhare of air to the plants, otherwiſe the fruit will not ſet; and if the ſeaſon ſhould prove very warm, the glaſſes may be frequently drawn off, eſpecially in an evening, to receive the dews, provided there is but little wind ſtirring; but the glaſſes ſhould not remain off the whole night, leſt the cold ſhould prove too great; but in warm weather, the glaſſes may be kept off from ten in the morning till evening.

When the plants have extended themſelves from under the frames, if the weather ſhould alter to cold, it will be neceſſary to cover their extremities every night with mats; for if theſe ſhoots are injured, it will retard the growth of the fruit, and often proves very injurious to the plants: and now what water is given to the plants, ſhould be in the alleys between the beds; for as the roots of the Vines will by this time have extended themſelves through the alleys, ſo when the ground there is well moiſtened, the plants will receive the benefit of it; and by this method, the ſtems of the plants will be preſerved dry, whereby they will continue ſound; but theſe waterings ſhould not be repeated oftener than once a week in very dry warm weather, and be ſure to give as much air as poſſible to the plants when the ſeaſon is warm.

Having given full inſtructions for the management of thoſe Melons which are raiſed under frames, I ſhall next proceed to treat of thoſe which are raiſed under bell or hand-glaſſes. The plants for theſe muſt be raiſed in the ſame manner as hath been already directed, and about the latter end of Aprril, if the ſeaſon proves forward, will be a good time to make the beds; therefore a ſufficient quantity of hot dung ſhould be provided, in proportion to the intended number of glaſſes, allowing ſix or eight good wheelbarrows of dung to each glaſs. Where there is but one bed, which is propoſed to be extended in length, the trench ſhould be dug out four feet and a half wide, and the length according to the number of glaſſes, which ſhould not be placed nearer than four feet to each other; for when the plants are too near each other, the Vines will intermix, and fill the bed ſo cloſely as to prevent the fruit from ſetting: in digging the trench, it ſhould be ſo ſituated, as to allow for the widening of the bed three or four feet on each ſide; the depth muſt be according as the ſoil is dry or wet; but, as was before obſerved, if the ſoil is ſo dry as that there is no danger of the beds being hurt by the wet, the lower they are made in the ground the better: in the making of the beds, the ſame regard muſt be had to the well mixing and laying of the dung as was before directed; and after the dung is laid, there ſhould be a hill of earth raiſed, where each plant is to ſtand, one foot and a half high; the other part of the bed need not as yet be covered more than four inches thick, which will be ſufficient to keep the warmth of the dung from evaporating; then the glaſſes ſhould be placed over the hills, and ſet down cloſe, in order to warm the earth of the hills to receive the plants; and if the beds work kindly, they will be in a proper temperature to receive the plants in two or three days after making; then the plants ſhould be removed, in the ſame manner as was before directed; and if they are in pots, ſo that there will be no danger of their growing, there ſhould but one plant be put under each glaſs; and if they are not in pots, there ſhould be two, one of which may be afterward taken away, if they both grow. Theſe plants muſt be watered at firſt planting, to ſettle the earth to their roots, and ſhaded every day until they have taken new root; and if the nights prove cold, it will be proper to cover the glaſſes with mats, to preſerve the warmth of the bed.

Where there are ſeveral of the beds intended, they ſhould be placed at eight feet diſtance from each other, that there may be a proper ſpace left between them, to be afterward filled up, for the root of the Vines to have room for extending themſelves, for the reaſons before given.

When the plants have taken good root in the beds, their tops muſt be pinched off; and their pruning, &c. muſt, from time to time, be the ſame as for thoſe under the frames. In the day time, when the weather is warm, the glaſſes ſhould be raiſed on the oppoſite ſide to the wind, to admit freſh air to the plants; for where this is not obſerved, they will draw up weak and ſickly, therefore all poſſible care ſhould be taken to prevent this; for if the runners have not proper ſtrength, they can never ſupply the fruit with nouriſhment.

When the plants are grown ſo long as to reach the ſides of the glaſſes, if the weather proves favourable, the glaſſes muſt be ſet on three bricks, ſo as to raiſe them about two inches from the ſurface of the beds, to give room for the Vines to run out from under them; but when this is done, the beds ſhould be covered all over with earth to the depth of one foot and a half, and trod down as cloſe as poſſible; and if the nights ſhould prove cold, there ſhould be a covering of mats put over the beds, to prevent the cold from injuring the tender ſhoots of the Vines; but as the Vines of the Contaleupe Melons are impatient of wet, it will be neceſſary to arch the beds over with hoops to ſupport the mats, that they may be ready for covering at all times when they require it; which is the only ſure method to have theſe Melons ſucceed in England, where the weather is ſo very uncertain and variable; for I have had ſome beds of theſe Melons in as fine order under theſe glaſſes as could be deſired, which were totally deſtroyed by one day's heavy rain in June.

After the thickneſs of earth is laid upon the beds, if the weather ſhould prove cold, it will be adviſeable to dig trenches on each ſide of the beds, into which you ſhould lay a ſufficient quantity of hot dung, to make it of the ſame thickneſs with the bed, after the manner before directed for the frames; or if there is a ſufficient quantity of hot dung ready, the whole ſpace between the beds may be dug out and filled up with the dung, laying thereon the earth a foot and a half deep, treading it down cloſe; this new dung will add a freſh warmth to the beds, and cauſe the plants to ſhew fruit ſoon after.

The watering of theſe plants muſt be done with great caution, and not given to their ſtems; the pinching off the runners muſt alſo be duly attended to, as alſo the pulling off all ſuperfluous fruit, to encourage thoſe which are deſigned to remain: and in ſhort, every thing before directed for thoſe under frames, muſt likewiſe be obſerved for theſe; and the further care is, to cover them in all hard rains and cold nights, with mats, which, if performed with care, there will be little danger of their miſcarrying, and theſe Vines will remain vigorous until the cold in autumn deſtroys them.

There have been many perſons, who of late years have raiſed their Melons under oiled paper, and in many places they have ſucceeded well; but where this is practiſed, there muſt be great care taken not to keep theſe coverings too cloſe over them; for where that is done, the Vines will draw very weak, and rarely ſet their fruit in any plenty; therefore where theſe coverings are propoſed to be uſed, I ſhould adviſe the bringing up of the plants under hand or bell-glaſſes, in the manner before directed, until they are grown far enough to be let out from under the glaſſes; and then, inſtead of the covering with mats, to put over the oiled paper; and if this covering is prudently managed, it will be the beſt that can be uſed. The beſt ſort of paper for this purpoſe is that which is ſtrong, and not of too dark a colour; and it ſhould be done over with linſeed oil, which will dry ſoon. There ſhould be a proportionable number of ſheets of this paper paſted together, as will ſpread to the dimenſions of the frame to which it is faſtened; and if this is fixed to the frame, before the oil is rubbed over it, ſo much the better; but this ſhould be done ſo long before they are uſed, as that the oil may be thoroughly dry, and the ſtench gone off, otherwiſe it will deſtroy the plants.

There are ſome perſons who make theſe frames of broad hoops, in imitation of the covers of waggons; but as theſe are cumberſome to move, and there are no conveniencies for admitting air to the plants, but by raiſing the whole frame on one ſide, I prefer thoſe made of pantile laths, framed like the ridge of a houſe; and each ſlope having hinges, may be raiſed at pleaſure to admit the air to the plants; but as deſcriptions of theſe things are not well comprehended by perſons not ſo converſant with them, I ſhall exhibit a figure of one of theſe frames, to be added to the article of Stoves.

The further management of the Melons, after their fruit is ſet, is to keep pulling off all the ſuperfluous fruit, and to pinch off all weak runners, which may draw away part of the nouriſhment from the fruit; as alſo to turn the fruit gently twice a week, that each ſide may have equal benefit of the ſun and air; for when they are ſuffered to lie with the ſame ſide conſtantly to the ground, that ſide will become of a pale or whitiſh colour, as if it were blanched, for want of the advantages of the ſun and air. The plants will require a little water in very dry weather, but this ſhould be given them in the alleys at a diſtance from the ſtems of the plants, and not oftener than once in a week or ten days, at which time the ground ſhould be well ſoaked in the alleys. This will encourage the growth of the fruit, and cauſe the fleſh to be thick; but the great caution which is neceſſary to be obſerved, is not to over-water the plants, which is certain injury to them: alſo be ſure to give as much free air as poſſible, at all times, when the weather will permit, for this is abſolutely neceſſary to render the fruit good.

When the fruit is fully grown, they muſt be duly watched to cut them at a proper time; for if they are left a few hours too long upon the Vines, they will loſe much of their delicacy, therefore they ſhould be looked over at leaſt twice every day; and if thoſe fruit which are intended for the table, are cut early in the morning, before the ſun has warmed them, they will be much better flavoured; but if any ſhould require to be cut afterward, they ſhould be put into cold ſpring water, or ice, to cool them, before they are brought to the table: and thoſe cut in the morning, ſhould be kept in the cooleſt place till they are ſerved up to table. The ſign of this fruit's maturity is, that of its beginning to crack near the foot-ſtalk, and its beginning to ſmell, which never fail; for as theſe Cantaleupe Melons ſeldom change their colour until they are too ripe, that ſhould never be waited for.

The directions here given for the management of the Cantaleupe Melons, will be found equally good for all the other ſorts, as I have fully experienced; for in the common method of managing them, where the earth is laid but three or four inches thick, the plants are very apt to decay before the fruit is ripe; for their roots ſoon reach the dung, and are extended to the ſides of the bed, where their tender fibres are expoſed to the air and ſun, which cauſe the leaves of the plants to hang down in the heat of the day, ſo it is neceſſary to ſhade them with mats, to prevent their decay; and this alſo occaſions the watering of the plants often to keep them alive, which is alſo prejudicial to their roots; whereas when the beds are made of a proper width, and earthed of a ſufficient thickneſs, the plants will bear the ſtrongeſt heat of the ſun in this climate, without ſhewing the leaſt want of moiſture, or their leaves drooping, and they will continue in health till the autumn cold deſtroys them.

In ſaving of the ſeeds I need not repeat here, that only ſuch ſhould be regarded, which are taken from the firmeſt fruit, and thoſe which have the higheſt flavour; and if theſe are taken out with the pulp entire, without diſplacing the ſeeds, and ſuffered to remain in the pulp two or three days before it is waſhed out, the better; and then to preſerve only the heavy ſeeds, which ſink in the water.

MELOCACTUS. } See Cactus.
MELOCARDUUS. }

MELOCHIA, Jews Mallow.

The Characters are,

It hath a permanent empalement of one leaf, cut half way into five ſegments; the flower hath five large ſpreading petals; the ſtamina are involved in the tube of the germen, and have five ſummits. It has a roundiſh germen with five awl-ſhaped erect ſtyles, which are permanent, crowned by ſingle ſtigmas. The flower is ſucceeded by five-cornered roundiſh capſules, having five cells with two horns, in each cell is lodged one angular compreſſed ſeed.

This genus of plants is ranged in the firſt ſection of Linnæus's ſixteenth claſs, intitled Monadelphia Pentandria; the flowers of this claſs have their ſtamina and ſtyles connected in one houſe, and thoſe of this ſection have but five ſtamina.

The Species are,

1. Melochia (*Pyramidata*) floribus umbellatis oppoſitis foliis, capſulis pyramidatis pentagonis, angulis acutis, foliis nudis. Hort. Cliff. 343. *Jews Mallow with umbellated flowers placed oppoſite to the leaves, and five-cornered pyramidal capſules.* Althæa Braſiliana fruteſcens, incarnato flore, fagopyri ſemine. Pluk. Phyt. tab. 131. f. 3.
2. Melochia (*Tomentoſa*) floribus umbellatis axillaribus, capſulis pyramidatis pentagonis, angulis mucronatis, foliis tomentoſis. Lin. Sp. 943. *Jews Mallow with umbellated flowers at the wings of the ſtalk, five-cornered pyramidal capſules, and woolly leaves.* Abutilon herbaceum procumbens, betonicæ folio, flore purpureo. Sloan. Hiſt. Sp. 220.
3. Melochia (*Depreſſa*) floribus ſolitariis capſulis depreſſis pentagonis, anguſtis obtuſis ciliatis. Flor. Leyd. Prod. 348. *Jews Mallow with flowers growing ſingly, and five-cornered depreſſed capſules.* Abutilon Americanum, ribeſii foliis, flore carneo, fructu pentagono aſpero. Houſt. MSS.
4. Melochia (*Concatenata*) racemis confertis terminalibus, capſulis globoſis ſeſſilibus. Flor. Zeyl. 247. *Jews Mallow with cluſtered ſpikes terminating the ſtalks, and globular capſules ſitting cloſe.*
5. Melochia (*Supina*) floribus capititatis, foliis ovatis ſerratis, caulibus procumbentibus. Lin. Sp. 944. *Jews Mallow with flowers in heads, oval ſawed leaves, and trailing ſtalks.* Alcea ſupina puſilla, geranii exigui maritimi folio & facie, maderaſpatenſis, fructu in ſummo caule glomerato, pericarpio duro. Pluk. Phyt. tab. 132. f. 4.

The firſt ſort grows naturally in the Brazils as a common weed, having a ſtalk ſomewhat ſhrubby, which riſes four or five feet high; the flowers are produced in umbels from the ſide of the ſtalk, oppoſite to the leaves; they are of a pale fleſh colour, and are ſucceeded by pyramidal capſules with five corners having five cells, each containing one angular ſeed.

The ſecond ſort grows naturally in Jamaica, and other warm parts of America. This has a trailing herbaceous ſtalk, garniſhed with woolly leaves ſhaped like Betony. The flowers are produced in umbels at the wings of the ſtalk; they are of a purple colour, and are ſucceeded by pyramidal capſules, having five corners.

The third ſort was diſcovered growing naturally at the Havannah, by the late Dr. Houſtoun. This riſes with a ſhrubby ſtalk five or ſix feet high, garniſhed with angular leaves reſembling thoſe of the Currant buſh; the flowers are produced ſingly from the ſide of the ſtalk: they are of a fleſh colour, and in ſhape like thoſe of the ſmall flowering Mallow; theſe are ſucceeded by rough five-cornered capſules, incloſing five Mallow-ſhaped ſeeds.

The fourth ſort grows naturally in both Indies; this hath an herbaceous ſtalk, which is terminated by ſeveral oblong bunches of flowers, which are ſucceeded by globular capſules with five cells, in each of which is lodged a ſingle ſeed.

The fifth ſort grows naturally in India; this is an annual plant with trailing ſtalks which ſpread on the ground, garniſhed with ſmall Betony-ſhaped leaves; the flowers and fruit are produced in cluſters at the end of the branches.

Theſe plants are preſerved in botanic gardens for variety, but having little beauty they are rarely cultivated in other places; they are propagated by ſeeds which muſt be ſown on a hot-bed, and when the plants come up, they ſhould be treated in the ſame way as is directed for Sida, to which the reader is deſired to turn to avoid repetition. The firſt and third ſorts are ſhrubby, ſo may with care be preſerved thro' the winter in a ſtove, whereby good ſeeds may be obtained; for theſe ſeldom ripen their ſeeds well the firſt year, unleſs the plants are brought forward early in the ſpring, and the ſummer proves warm. The other three ſorts generally ripen their ſeeds the ſame year they are ſown.

MELON. See Melo.

MELONGENA. Tourn. Inſt. R. H. 151. tab. 65. Solanum. Lin. Gen. Plant. 224. Mad Apple, by ſome called Egg Plant; in French, *Mayenne*.

The Characters are,

The flower has a permanent empalement of one leaf, which is deeply cut into five acute ſegments, which ſpread open. The flower hath but one petal, which is cut into five parts, which ſpread open and are reflexed. It hath five awl-ſhaped ſtamina, terminated by oblong ſummits which converge together. In the center is ſituated an oblong germen ſupporting a ſlender ſtyle, crowned by an obtuſe ſtigma; the germen afterward becomes an oval or oblong fruit with one cell, which hath a fleſhy pulp, filled with compreſſed roundiſh ſeeds.

This genus of plants is ranged in the ſeventh ſection of Tournefort's ſecond claſs, which includes the herbs with a wheel-ſhaped flower of one leaf, whoſe pointal changes to a ſoft fruit. Dr. Linnæus has joined this genus, and the Lycoperſicon of Tournefort, to the Solanum, making them only ſpecies of that genus; but as the fruit of this genus has but one cell, ſo it ſhould be ſeparated from the Solanum, whoſe fruit have two cells, and of which there are ſo many ſpecies already known, that there need not be any addition of plants which can be ſeparated with propriety added to it; he places it in the firſt ſection of his fifth claſs.

The Species are,

1. **Melongena** (*Ovata*) caule inermi herbaceo, foliis oblongo-ovatis tomentoſis integris, fructu ovato. *Mad Apple with a ſmooth herbaceous ſtalk, oblong, oval, woolly leaves, which are entire, and an oval fruit.* Melongena fructu oblongo violaceo. Tourn. Inſt. 151. *Mad Apple with an oblong Violet-coloured fruit.*
2. **Melongena** (*Tereta*) caule inermi herbaceo, foliis oblongo-ovatis tomentoſis, fructu tereti. *Mad Apple with herbaceous, ſmooth, oblong, oval, woolly leaves, and a taper fruit.* Melongena fructu tereti violaceo. Tourn. Inſt. 151. *Mad Apple with a taper Violet-coloured fruit.*
3. **Melongena** (*Incurva*) caule inermi herbaceo, foliis oblongis ſinuatis tomentoſis, fructu incurvo. *Mad Apple with a ſmooth herbaceous ſtalk, oblong ſinuated leaves which are woolly, and an incurved fruit.* Melongena fructu incurvo. Tourn. Inſt. R. H. 152. *Mad Apple with an incurved fruit.*
4. **Melongena** (*Spinoſa*) ſpinoſa, foliis ſinuatis-laciniatis, fructu tereti, caule herbaceo. *Mad Apple, with a prickly ſtalk and leaves which are cut into ſinuſes, a taper fruit, and an herbaceous ſtalk.* Solanum pomiferum fructu ſpinoſo. J. B. 3. 619. *Apple-beariug Nightſhade with a prickly fruit.*

The firſt ſort grows naturally in Aſia, Africa, and America, where the fruit is commonly eaten by the inhabitants; and it is cultivated in the gardens in Spain as an eſculent fruit, by the title of Barenkeena; the Turks who alſo eat the fruit, call it Badinjan, the Italians Melanzana, and the inhabitants of the Britiſh iſlands in America, Brown John, or Brown Jolly. It is an annual plant with an herbaceous ſtalk, which becomes a little ligneous, and riſes near three feet high, ſending out many ſide branches, garniſhed with oblong oval leaves ſeven or eight inches long, and four broad; they are woolly, and their borders are very ſlightly ſinuated, but not indented, ſtanding without order upon very thick foot-ſtalks. The flowers come out ſingly from the ſide of the branches, having a thick fleſhy empalement of one leaf, which is deeply cut into five acute ſegments, which ſpread open, and is armed with ſtrong prickles on the outſide. The flowers have one petal, which is cut at the brim into five ſegments, which expand in form of a ſtar, and are a little reflexed; they are blue, and the ſummits which are connected together in the boſom of the flower are yellow. The flowers are ſucceeded by oval fleſhy fruit, about the ſize and ſhape of a ſwan's egg, of a dark purple on one ſide, and white on the other. The flowers come out in June and July, and the fruit ripens in September.

There are the following varieties of theſe ſpecies; one with white fruit, called by ſome the Egg Plant; one with yellow fruit, and another with pale red fruit; all theſe varieties are generally conſtant, the ſeeds producing the ſame fruit as thoſe from which they were taken, but as they only differ in colour, ſo I chuſe not to enumerate them as diſtinct ſpecies.

The ſecond ſort differs from the firſt in the ſhape of the fruit, which is commonly eight or nine inches long, taper and ſtrait; in other reſpects they are the ſame, but as this never varies when propagated in gardens, ſo there can be no doubt of their being diſtinct ſpecies. There are two varieties of this ſort, one with a purpliſh fruit, and the other white, but the latter is the moſt common in England.

The third ſort differs from the two former in the ſhape of the leaves, which are deeply ſinuated on their borders. The fruit is oblong and incurved, of a yellowiſh colour, and larger at the end than in any other part.

The ſeeds of the fourth ſort were ſent me from India; this differs greatly from either of the former. The ſtalks and leaves are armed with very ſtrong thorns, and the leaves are larger, and deeply jagged on their ſides. The flowers are larger, and of a deeper blue colour. The fruit is long, taper, and white.

Theſe fruit are eaten by moſt of the inhabitants of the warm parts of the globe, and are eſteemed a delicacy, but are ſuppoſed to have a property of provoking luſt.

They are propagated by ſeeds, which muſt be ſown upon a moderate hot-bed in March, and when the plants come up, they muſt be tranſplanted into another hot-bed about four inches aſunder, obſerving to water and ſhade them until they have taken root; after which you muſt give them a great ſhare of air when the weather is warm, otherwiſe they will draw up very weak. They muſt be alſo frequently watered, without which they will make but very indifferent progreſs; but when they are grown ſo ſtrong as to fill the frame (which will be by the middle or end of May,) you muſt tranſplant them out into a rich ſpot of ground, at two feet diſtance, or in the borders of the pleaſure-garden at the ſame diſtance from other plants, obſerving to preſerve as much earth to the roots as poſſible when you take them up, otherwiſe they are ſubject to miſcarry. You muſt obſerve to water them plentifully, and ſhade them until they have taken root, after which they will require but very little care, more than to keep them clear from weeds, and in very dry weather to give them ſome water.

About the middle of July the fruit will appear, at which time, if the weather ſhould be very dry, you muſt often water them, which will cauſe the fruit to grow very large, and increaſe their number: toward the latter end of Auguſt their fruit will ripen, when you muſt preſerve the ſeeds of each kind ſeparate; but thoſe for the table ſhould be gathered before they are quite ripe.

Theſe plants are only preſerved as curioſities in the Engliſh gardens, the fruit being ſeldom eaten in this country, except by ſome Italians or Spaniards, who have been accuſtomed to eat them in their own countries.

MELOPEPO. See Cucurbita.

MELONRY, or MELON GROUND, is an apartment in the kitchen-garden for the propagation of Melons only.

This ſpot of ground ſhould be open to the ſouth-eaſt ſun, but ſheltered from the weſt, north-weſt, and north-eaſt winds, by walls, pales, or hedges, the latter of theſe is the beſt; it ſhould alſo be upon a dry ſoil, for nothing is more injurious to theſe plants than much wet; for in the ſpring of the year it often proves very wet weather, when, if the ſoil is very wet, there will be no making the ridges until it is very late. This ſhould alſo be contrived as near to the dung as poſſible, which will ſave a great deal of labour in wheeling the dung; and, if there ſhould be a pond of water near it, which, in very dry weather, will be very uſeful to water the Melons when it is neceſſary, though it is not often that water is wanted for this purpoſe in England.

As to the ſize of the ground, that muſt be proportioned to the quantity of ridges intended, which you may eaſily calculate, by allowing twelve feet breadth for every ridge, and the holes placed at about four feet aſunder; but it is the beſt way to allow room enough where you are not ſtreightened to it.

This ground ſhould be incloſed with a Reed fence, and kept conſtantly locked up during the time that the Melons are growing, for if they are expoſed to every perſon that walks in the garden (moſt of whom have a curioſity to handle the Vines, and look after the fruit,) it will be of ill conſequence, nothing being more injurious to theſe plants than frequent tumbling or diſturbing their leaves.

The common practice in moſt gentlemens gardens is, to incloſe a ſpot of ground either with walls or pales, which they conſtantly appropriate to this purpoſe;

but this is by no means a good method, for it rarely happens that theſe ſucceed well longer than two years in the ſame place, unleſs the ſoil be removed and freſh brought in, which is very expenſive; therefore the beſt way is, to have a ſufficient parcel of Reeds made into pannels, which may be annually moved from place to place, ſo that you need not continue your ridges longer than one year in the ſame place; and if you have a piece of ground which is large enough to divide into three or four ſuch places, the fence may be every year removed till the whole has been occupied, after which you may return to the ſpot where you began, which, by that time, will be as good as freſh earth; and hereby, without much trouble, you may remove them every year, for as one of the ſides will remain unremoved every time the fence is carried forward, the labour will not be ſo great as if it were wholly removed to ſome diſtance, and theſe Reed fences are much preferable to either walls or pales, for this purpoſe.

MELOTHRIA. Lin. Gen. Plant. 48.

The title of this genus was applied to it by Dr. Linnæus in the Hortus Cliffortianus. By ſome authors it hath been placed under the genus of Cucumis, and by others under that of Bryonia; but the Doctor has removed this to a diſtance from either of thoſe genera, on account of its having but three ſtamina; but Dr. Van Royen has brought it next to the genus of Bryonia again, as the plants have male and hermaphrodite flowers.

The Characters are,

The empalement of the flower is of one leaf, bell-ſhaped, and cut ſlightly at the brim into five parts, and in the hermaphrodite flowers, reſts upon the embryo. The male flower is of one leaf, wheel-ſhaped, having a tube the length of the empalement. In the center of the hermaphrodite flower is ſituated the pointal, ſupporting a cylindrical ſtyle, attended by three conical ſtamina, which are inſerted in the tube of the flower, and are extended to the ſame length; the male flowers have three ſtamina, terminated by blunt ſtyles. The pointal afterward becomes an oval ſmall berry, having three diviſions, in which are lodged ſmall flat ſeeds.

We have but one Species of this plant, viz.

Melothria (*Pendula.*) Lin. Hort. Cliff. 490. *Small creeping Cucumber.* Cucumis minima fructu ovali nigro lævi. Sloan. Hiſt. 1. p. 227. *Smalleſt Cucumber with a ſmooth, black, oval fruit.*

This plant grows wild in the woods in Carolina, Virginia, and alſo in many of the iſlands in America; it creeps upon the ground with ſlender Vines, having angular leaves, ſomewhat reſembling thoſe of the Melon, but much ſmaller. Theſe Vines ſtrike out roots at every joint, which faſten themſelves into the ground, and thereby a larger ſhare of nouriſhment is drawn to the plants, by which means their ſtalks extend to a great diſtance each way, and cloſely cover the ground. The flowers are very ſmall, in ſhape like thoſe of the Melon, and of a pale ſulphur colour. The fruit, in the Weſt-Indies, grow to the ſize of a Pea, of an oval figure, and changes black when ripe; theſe are by the inhabitants ſometimes pickled when they are green.

In England the fruit are much ſmaller, and are ſo hidden by the leaves, as to render it difficult to find them. The plants will not grow in the open air here, but the ſeeds muſt be ſown upon a hot-bed, and if the plants are permitted, will ſoon ſpread over the ſurface of a large bed; and when the fruit is ripe, if they ſcatter their ſeeds, the plants will come up where the earth happens to be uſed on a hot-bed again, and if they are ſupplied with water, will require no farther care. This plant is in ſome gardens preſerved for the ſake of variety, but is of no uſe.

MENISPERMUM. Tourn. Act. R. Par. 1705. Lin. Gen. Plant. 1131. Moonſeed.

The Characters are,

It hath male and female flowers on different plants; the male flowers have empalements compoſed of two ſhort linear leaves, and have four oval ſpreading petals without ſide, and eight oval concave petals within, which are ſmaller than thoſe without, ranged in four ſeries, and many cylindrical ſtamina which are longer than the petals, terminated by ſhort obtuſe ſummits having four lobes. The female flowers have the ſame empalement and corolla as the male, and have eight ſtamina with pellucid ſummits, which are fruitful. Theſe have two oval incurved germina, ſupporting a ſolitary recurved ſtyle, crowned by a bifid ſtigma; the germen afterward become two roundiſh kidney-ſhaped berries of one cell, incloſing a large kidney-ſhaped ſeed.

This genus of plants is ranged in the tenth ſection of Linnæus's twenty-ſecond claſs, which includes thoſe plants which have male and female flowers on different plants, and the male flowers have twelve ſtamina.

The Species are,

1. Menispermum (*Canadenſe*) foliis peltatis ſubrotundis angulatis. Hort. Cliff. 140. *Moonſeed with target-ſhaped, roundiſh, angular leaves.* Meniſpermum Canadenſe ſcandens, umbilicatis foliis. Tourn. Act. Par. 1705. *Climbing Moonſeed of Canada, with a navel-ſhaped leaf.*
2. Menispermum (*Virginicum*) foliis cordatis peltatis lobatis. Flor. Virg. 40. *Moonſeed with heart and target-ſhaped leaves, which have lobes.* Meniſpermum folio hederaceo. Hort. Elth. 223. tab. 178. *Moonſeed with an Ivy leaf.*
3. Menispermum (*Carinianum*) foliis cordatis ſubtus villoſis. Lin. Sp. Plant. 340. *Moonſeed with heart-ſhaped leaves, which are hairy on their under ſide.*

The firſt ſort grows naturally in Canada, and moſt parts of North America, in the woods; this hath a thick ligneous root, from which are ſent out many climbing ſtalks, which become ligneous, and riſe to the height of twelve or fourteen feet, twiſting themſelves about the neighbouring plants for ſupport; theſe are garniſhed with large, ſmooth, roundiſh leaves, whoſe foot-ſtalks are placed almoſt in the middle of the back of the leaves; on the upper ſide there is a hollow in that part of the leaf reſembling a navel. The flowers come out in looſe bunches from the ſide of the ſtalks; they are of an herbaceous colour, ſmall, and compoſed of two tiers of oblong oval petals, very ſhort ſtamina, with ten in the male flowers, terminated by ſingle ſummits; the two germen ſituated in the center of the female flowers turn to ſo many channelled berries, each containing one kidney-ſhaped ſeed. It flowers in July, and the ſeeds ripen in autumn.

This ſort may be eaſily propagated by laying down of the branches, which, if performed in autumn, will have made good roots by the following autumn, when they may be ſeparated from the old plant, and tranſplanted where they are deſigned to remain; theſe plants require ſupport, for their branches are ſlender and weak. In the country where it grows naturally, they climb up the trees to a conſiderable height, ſo that if theſe are planted near trees in wilderneſs quarters, where their ſtalks may have ſupport, they will thrive better than in an open ſituation.

The ſecond ſort differs from the firſt in the ſhape of its leaves, which are angular, and ſometimes heart-ſhaped; their foot-ſtalks join to the baſe of the leaves, ſo they have no umbilical mark on their ſurface. The ſtalks of this become ligneous, and riſe nearly as high as thoſe of the firſt ſort, and the flowers and berries do not differ from them. It is alſo propagated after the ſame manner.

The third ſort grows naturally in Carolina, from whence the ſeeds were ſent to England; this has by ſome been ſuppoſed the ſame with the ſecond ſort, from which it differs in its branches, not becoming woody as thoſe do. The ſtalks are herbaceous; the leaves are entire and hairy, and are not more than half ſo large as thoſe of the ſecond, nor is the plant ſo hardy, for in ſevere winters, thoſe which are expoſed to the open air are ſometimes killed, whereas the ſecond ſort is never injured by cold. This ſort does not produce any flowers in England, unleſs the ſeaſon proves very warm.

This may be propagated by parting of the roots, which ſpread out on the ſide, ſo that part of them may be cut off every other year; the beſt time for doing this is in the ſpring, a little before the plants begin to ſhoot; theſe ſhould be planted in a warm ſituation and have a light ſoil, for in ſtrong land, where the wet is detained in winter, the roots are apt to rot; therefore if they are planted cloſe to a wall expoſed to the ſouth or weſt, their ſtalks may be faſtened againſt the wall, to prevent their trailing upon the ground; and in this ſituation the plants will frequently flower, and by having a little ſhelter in ſevere froſt, their ſtalks may be preſerved from injury.

There is little beauty in theſe plants, but yet they are preſerved in many gardens for the ſake of variety, for which reaſon they are here inſerted.

MENTHA. Tourn. Inſt. R. H. 188. tab. 89. Lin. Gen. Plant. 633. [Μίνθη, according to the ancients, a goddeſs, as alſo according to the poets. The ancients alſo gave it the name of Sweet-ſmelling, and where this word is found, this plant is underſtood. Mentha is likewiſe ſo called of Mens, *Lat.* the mind, becauſe this plant is ſaid to ſtrengthen the mind.] Mint; in French, *Menthe*.

The CHARACTERS are,

It hath a lip flower of one petal, ſitting on a permanent tubulous empalement of one leaf, which is erect, and cut at the brim into five equal ſegments. The tube of the petal is a little longer than the empalement. The chaps are cut into four almoſt equal ſegments, the upper being a little larger and indented. It hath four awl-ſhaped ſtamina, which are erect, ſtanding aſunder, the two neareſt being longeſt; they are terminated by roundiſh ſummits, and in the bottom of the tube is ſituated a four-pointed germen, ſupporting a ſlender erect ſtyle, crowned by a bifid ſpreading ſtigma. The germen afterward turns to four naked ſeeds ſitting in the empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's fourteenth claſs, which includes thoſe plants whoſe flowers have two long and two ſhorter ſtamina, and the ſeeds ripen in the empalement.

The SPECIES are,

1. MENTHA (*Viridis*) floribus ſpicatis, foliis oblongis ſerratis. Hort. Upſal. 168. *Mint with ſpiked flowers, and oblong ſawed leaves.* Mentha anguſtifolia ſpicata. C. B. P. 227. *Narrow-leaved ſpiked Mint, commonly called Spear Mint.*
2. MENTHA (*Glabra*) floribus ſpicatis, foliis longioribus glabris, ſupernè minimè ſerratis. *Mint with ſpiked flowers, and longer ſmooth leaves, which are very ſlightly ſawed toward their points.* Mentha anguſtifolia ſpicata glabra. Rand. *Narrow-leaved, ſmooth, ſpiked Mint.*
3. MENTHA (*Candicans*) foliis lanceolatis ſerratis, ſubtus incanis, floribus ſpicatis hirſutiſſimis. *Mint with ſpear-ſhaped ſawed leaves, which are hoary on their under ſide, and very hairy ſpiked flowers.* Mentha Sylveſtris candicans, odore ſativi. Doody. Raii Syn. App. *Wild Mint of a white colour, ſmelling like that of the garden.*
4. MENTHA (*Sylveſtris*) ſpicis confertis, foliis ſerratis tomentoſis ſeſſilibus. Hort. Cliff. 306. *Mint with ſpikes of flowers growing in cluſters, and woolly ſawed leaves ſitting cloſe to the ſtalks.* Mentha ſylveſtris longiore folio. C. B. P. 227. *Wild Mint with a longer leaf.*
5. MENTHA (*Aquatica*) ſpicis craſſioribus, foliis ovato-lanceolatis ſerratis ſubtus tomentoſis petiolatis. *Mint with thicker ſpikes, and oval, ſpear-ſhaped, ſawed leaves, which are woolly on their under ſide, and have foot-ſtalks.* Mentaſtri aquatici genus hirſutum, ſpicâ latiore. J. B. 3. 222. *Hairy Water Mint with a broader ſpike.*
6. MENTHA (*Piperita*) ſpicis craſſioribus interruptis, foliis lanceolatis acutè ſerratis. *Mint with thicker ſpikes of flowers, which are interrupted, and ſpear-ſhaped leaves which are ſharply ſawed.* Mentha fervida nigricans, piperis ſapore. Rand. Hort. Chel. Cat. *Blackiſh hot Mint with a taſte like Pepper, commonly called Pepper Mint.*
7. MENTHA (*Criſpa*) floribus ſpicatis, foliis cordatis dentatis undulatis ſeſſilibus. Hort. Cliff. 306. *Mint with ſpiked flowers, and heart-ſhaped indented leaves, which are waved, and ſit cloſe to the ſtalks.* Mentha criſpa Danica ſive Germanica ſpecioſa. Mor. Hiſt. 3. p. 367. *Daniſh or German curled Mint.*
8. MENTHA (*Rotundifolia*) ſpicis confertis, foliis ovatis rugoſis ſeſſilibus. *Mint with ſpikes growing together, and oval rough leaves ſitting cloſe to the ſtalk.* Mentaſtrum folio rugoſo rotundiore ſpontaneum, flore ſpicato, odore gravi. J. B. 3. 217. *Wild Mint with a rounder rough leaf, and a ſpiked flower, having a ſtrong ſcent.*
9. MENTHA (*Rubra*) ſpicis confertis interruptis, foliis oblongo-ovatis acuminatis dentatis ſeſſilibus. *Mint with interrupted ſpikes of flowers growing together, and oblong, oval, acute-pointed, indented leaves, ſitting cloſe to the ſtalk.* Mentha rotundifolia rubra, aurantii odore. Mor. Hiſt. 3. 369. *Round-leaved red Mint, ſmelling like an Orange, commonly called Orange Mint.*
10. MENTHA (*Chalepenſa*) foliis oblongis dentatis, utrinque tomentoſis ſeſſilibus, ſpicis tenuioribus. *Mint with oblong indented leaves, which are woolly on both ſides, ſet cloſe to the ſtalk, and very narrow ſpikes of flowers.* Mentraſtum chalepenſe, anguſtifolium, rarò florens. Boerh. Ind. alt. 1. p. 185. *Narrow-leaved wild Mint of Aleppo, which rarely flowers.*
11. MENTHA (*Paluſtris*) floribus capitatis, foliis ovatis ſerratis petiolatis, ſtaminibus corollâ longioribus. Hort. Cliff. 306. *Mint with flowers growing in heads, oval ſawed leaves having foot-ſtalks, and ſtamina longer than the petals.* Mentha rotundifolia paluſtris ſive aquatica major. C. B. P. 227. *Greater round-leaved Water Mint.*
12. MENTHA (*Nigricans*) floribus capitatis, foliis lanceolatis ſerratis ſubpetiolatis. Lin. Sp. Plant. 576. *Mint with flowers growing in heads, and ſpear-ſhaped ſawed leaves with very ſhort foot-ſtalks.* Mentha fervida nigricans latifolia. Rand. *Broad-leaved blackiſh Pepper Mint.*
13. MENTHA (*Arvenſis*) floribus verticillatis, foliis ovatis acutis ſerratis, ſtaminibus corollâ brevioribus. Lin. Sp. Plant. 577. *Mint with flowers growing in whorls, oval, acute, ſawed leaves, and ſtamina ſhorter than the petals.* Mentha arvenſis, verticillata hirſuta. J. B. 3. 2. 217. *Whorled hairy field Mint, or Calamint of the ſhops.*
14. MENTHA (*Exigua*) floribus verticillatis, foliis ovatis dentatis, ſtaminibus corollâ longioribus. *Mint with flowers growing in whorls, oval indented leaves, and ſtamina longer than the petals.* Mentha aquatica, exigua. Trag. Lib. 1. c. 6. *Smalleſt Water Mint.*
15. MENTHA (*Gentilis*) floribus verticillatis, foliis ovatis, marginibus ciliatis, ſtaminibus corollam æquantibus. *Mint with whorled flowers, oval leaves whoſe borders are hairy, and ſtamina equalling the petals.* Mentha verticillata, rotundiore folio, odore ocymi. Dale. *Whorled Mint with a rounder leaf, ſmelling like Baſil.*
16. MENTHA (*Hirſuta*) floribus verticillatis, foliis ovatis ſerratis hirſutis, ſtaminibus corollâ longioribus. *Mint with whorled flowers, oval, ſawed, hairy leaves, and ſtamina longer than the petals.* Mentha aquatica ſive ſiſymbrium hirſutus. J. B. 3. 2. 224. *Water Mint, or hairy Siſymbrium.*
17. MENTHA (*Verticillata*) floribus verticillatis, foliis lanceolatis acutis ſerratis, rugoſis, ſtaminibus corollam æquantibus. *Mint with whorled flowers, ſpear-ſhaped, acute-pointed, ſawed, rough leaves, and ſtamina equalling the petals.* Mentha verticillata, longiori acuminato folio, odore aromatico. Rand. Hort. Chel. Cat. *Whorled Mint with a longer acute-pointed leaf, and an aromatic ſcent.*

There are ſeveral other varieties of this genus, which have been found growing naturally in England, of which I have twelve or more in my own collection; but as I ſuſpect ſome of them to be only accidental variations, ariſing from the different ſoils and ſituations where they have been found, I have not enumerated them all here; thoſe which are here mentioned, I take to be diſtinct ſpecies, having cultivated them more than thirty years, in which time I have not obſerved them to change from one to another; ſeveral of theſe I have propagated by ſeeds, and have found them keep to the kind from which the ſeeds were ſaved.

The firſt ſort is what the gardeners cultivate to ſupply the markets, and is uſed both as a culinary herb, and for medicine; it is generally called Spear Mint, and by ſome Hart Mint; Parkinſon and Gerard title it Roman Mint; this is a plant ſo well known, as to need no deſcription. There are two varieties of this, one with a curled leaf, and the other has variegated leaves, but both theſe I have had run from the common ſort; theſe are by ſome preſerved in their gardens for the ſake of variety, therefore I have mentioned them here.

This herb is greatly eſteemed for all diſorders of the ſtomach, loſs of appetite, and vomiting; there is a ſimple water, a ſpirit, and compound ſyrup, and a diſtilled oil of it prepared in the ſhops.

The ſecond ſort hath ſmoother leaves than the firſt, and they are rather narrower, in other reſpects it agrees with that, ſo that it is frequently cultivated in the gardens for uſe, without diſtinction.

The third ſort grows naturally in England; the leaves of this are ſhorter, and broader in the middle than either of the former, the ſerratures on their edges are more acute, and their under ſides are woolly, and very white. The ſtalks divide more toward the top, ſo are terminated by a greater number of ſpikes, the lower part of which are interrupted. The ſcent of this ſort is very like that of the Garden Mint.

The fourth ſort hath longer and broader leaves than either of the former, which are woolly and white. The ſerratures on their edges are farther aſunder, and are very ſharp pointed; they ſit cloſe to the ſtalks, which are hairy. The ſpikes of flowers are ſlender, ſeveral of them growing together at the top of the ſtalk, which are hairy. This is the Mentaſtrum, or wild Mint of the ſhops, and is an ingredient in the Trochiſci de Myrrha.

The fifth ſort grows naturally in moiſt places in ſeveral parts of England, it is titled Spiked Horſe Mint, or Water Mint. The ſtalks of this are ſhorter than thoſe of either of the former, and are hairy, as are alſo the leaves, which are oval, ſpear-ſhaped, ſawed on their edges, and of a pale colour. The flowers grow in ſhort thick ſpikes at the top of the ſtalks, their ſtamina being ſhorter than the petal.

The ſixth ſort is found growing naturally in ſome parts of England; I have found it by the ſide of the river between Mitcham and Croydon, in Surry; this hath ſmooth purple ſtalks; the leaves are ſmaller than thoſe of common Mint; they are ſpear-ſhaped, ſawed on their edges, and of a darker green colour than either of the former; their midrib and veins are purple, and a little hairy on their under ſide. The ſpikes of flowers are ſhorter and thicker than thoſe of the common Mint, and are broken or interrupted at the bottom; they are of a dark purple colour, and their ſtamina are longer than the petal. The whole plant has a hot biting taſte like Pepper, and a pleaſant ſcent. There is a diſtilled water of this plant kept in the ſhops, which is by moſt people preferred to that of the common Mint, for all the purpoſes which that is uſually preſcribed, and is eſteemed an excellent remedy againſt the ſtone and gravel.

The ſeventh ſort was originally brought from Denmark, where it was thought to grow naturally, but Dr. Linnæus fixes it as a native of Siberia. The ſtalks of this ſort are hairy, and riſe about the ſame height with the common. The leaves are heart-ſhaped, deeply indented on their edges, waved and curled, and ſit cloſe to the ſtalk, they are of a light green. The flowers are purple, growing in thick interrupted ſpikes at the top of the ſtalks; their empalements are cut almoſt to the bottom, and the ſtyle of the flower is bifid, ſtanding out beyond the petal.

The eighth ſort grows naturally in many parts of England; this riſes with a ſtrong, four-cornered, hairy ſtalk, about the ſame height as the common Mint, branching out toward the top, and garniſhed with oval rough leaves ſitting cloſe to the ſtalks; they are of a dark green, and crenated on their edges. The ſpikes of flowers grow in cluſters at the top of the ſtalks, which are ſhort and cloſe; the flowers are of an herbaceous white colour, and their ſtamina are ſtretched out beyond the petal.

The ninth ſort is commonly called Orange Mint, from its ſcent, which is ſomewhat like that of the rind of Orange. This riſes with an upright ſmooth ſtalk about the ſame height with the common Mint, but does not branch out like that; the leaves are much broader than thoſe of the common ſort; the indentures on their edges are deep, and they end in acute points. The ſpikes of flowers grow in cluſters on the top of the ſtalks, which are interrupted; they are of a pale colour, and their ſtamina are ſhorter than the petal. It is commonly cultivated in gardens for its pleaſant ſcent.

The tenth ſort grows naturally at Aleppo, but is hardy enough to thrive in the open air in England. This hath ſlender four-cornered ſtalks, which are purple at bottom, but woolly upward, ſeldom branching; they are garniſhed with oblong indented leaves, which are downy on both ſides, ſitting cloſe to the ſtalks. The ſpikes of flowers are ſingle, and very ſlender; theſe do not often appear in England, but when they do it is late in the ſummer. It creeps much at the root, ſo the only way to obtain flowers, is to confine their roots in pots.

The eleventh ſort grows naturally in ditches in moſt parts of England, and is commonly known by the name of Water Mint. This hath hairy ſtalks about a foot high, which branch toward the top, and are garniſhed with oval ſawed leaves, ſtanding upon pretty long foot-ſtalks. The flowers grow in roundiſh ſpikes at the end of the branches; they are of a purple colour, and their ſtamina are longer than the petal. The whole plant has a very ſtrong ſcent, ſomewhat like that of Penny Royal. This ſort is ſometimes uſed in medicine, and is reckoned hotter than the Garden Mint: it is carminative, expelling wind out of the ſtomach, and helping the cholick.

The twelfth ſort grows naturally in ditches in ſeveral parts of England; the ſtalks of this are purple, ſmooth, and ſhort, branching out on every ſide; the leaves are ſmall, ſpear-ſhaped, of a dark colour; they are but ſlightly ſawed on their edges, and ſtand upon ſhort foot-ſtalks. The flowers grow in roundiſh heads on the top of the ſtalks, they are purple, and their ſtamina are longer than the petal. This ſort has a warm biting taſte, but not quite ſo hot as the Pepper Mint before deſcribed, but is often uſed for it. There is a variety of this which ſmells like Penny Royal.

The thirteenth ſort grows naturally in arable land in moſt parts of England, and is rarely admitted into gardens. This is the Water Calamint of the ſhops, but is now ſeldom uſed in medicine. The ſtalks of this ſort riſe about a foot high and are hairy, garniſhed with oval leaves ending in acute points, and ſawed on their edges. The flowers grow in very thick whorls round the ſtalks; they are ſmall, of a purple colour, and their ſtamina are ſhorter than the petal. The plant has a ſtrong ſcent like Penny Royal.

The fourteenth ſort grows in watery places in many parts of England; this hath weak trailing ſtalks a foot and a half long, garniſhed with ſmall oval leaves which are indented on their edges, and ſtand upon pretty long foot-ſtalks. The flowers grow in thick whorls round the ſtalks, they are purple, and their ſtamina are longer than the petal.

The fifteenth ſort grows plentifully on the ſide of the road between Bocking and Goſfield in Eſſex; the ſtalks of this are much ſmaller, and not ſo long as thoſe of the former; the leaves are ſhorter and rounder, and are very little indented on their edges, but have their borders ſet with hairs. The whorls of flowers are ſmaller, and the whole plant has the ſcent of Baſil.

The ſixteenth ſort grows naturally in ditches and on the ſides of rivers, in many parts of England. This hath hairy four-cornered ſtalks, which are a foot or more in height; the leaves are oval, ſawed, and very hairy. The flowers grow in large whorls toward the top of the ſtalks; they are purple, and their ſtamina are longer than the petals. This hath a pleaſanter ſcent than the common Water Mint, ſo is called Sweet Water Mint by way of diſtinction: it ſtands in the liſt of ſimples in moſt diſpenſaries, but is now ſeldom uſed in medicine.

The ſeventeenth grows naturally by the ſide of the river Medway, between Rocheſter and Chatham. This riſes with ſlender hairy ſtalks near two feet high, garniſhed with ſpear-ſhaped leaves, ending in acute points, which are ſawed on their edges; the ſtalks are beſet with whorls of flowers almoſt their whole length, ſo that they have frequently ten or twelve whorls on each. The flowers are purpliſh, and their ſtamina are equal with the petals; this hath a very pleaſant aromatic ſcent.

All the ſorts of Mint are eaſily propagated by parting the roots in the ſpring, or by planting cuttings during any of the ſummer months, but they ſhould have a moiſt ſoil; and after the cuttings are planted, if the ſeaſon ſhould prove dry, they muſt be often watered until they have taken root; after which, they will require no farther care but to keep them clear from weeds: they ſhould be planted in beds about four feet wide, allowing a path about two feet broad between the beds, to water, weed, and cut the plants. The diſtance they ſhould be ſet is four or five inches, or more, becauſe they ſpread very much at their roots; for which reaſon, the beds ſhould not ſtand longer than three years before you plant freſh, for by that time the roots will be matted ſo cloſely, as to rot and decay each other, if permitted to ſtand longer. There are ſome people who are very fond of Mint ſallad in winter and ſpring; in order to obtain which, they take up the roots before Chriſtmas, and plant them upon a moderate hot-bed pretty cloſe, covering them with fine earth about an inch thick, and cover the bed either with mats or frames of glaſs. In theſe beds the Mint will come up in a month's time, and be ſoon fit to cut for that purpoſe.

When the herb is cut for medicinal uſe, it ſhould be done in a very dry ſeaſon, juſt when it is in flower; for if it ſtand longer, it will not be near ſo handſome, nor ſo well taſted; and if it be cut when it is wet, it will change black and be little worth; this ſhould be hung up to dry in a ſhady place, where it may remain until it be uſed.

If the ſoil be good in which theſe plants are ſet, they will afford three crops every year, but after July they ſeldom prove good; therefore what ſhoots are produced after that time ſhould be permitted to remain till Michaelmas, when they muſt be cut down cloſe; and after having cleared the beds from weeds, you ſhould ſpread a little fine rich earth all over them, which will greatly encourage the roots againſt the ſucceeding ſpring.

As the diſtilled water of all the ſorts of Mint is eſteemed a very wholeſome cordial dram, ſo I ſhould think it might be ſubſtituted inſtead of thoſe vile ſpirits with which the common people intoxicate themſelves; for the Pepper Mint water is as warm on the ſtomach as any ſort of dram, and more ſo than any of thoſe noxious ſpirits; and if this was mixed with ſome other agreeable aromatic herbs, there might certainly be a diſtilled liquor much more palatable and wholeſome than what is now vended in common; for as the generality of the lower claſs of people are ſo debauched, as not to be contented without drams, ſo the leſs hurtful thoſe are made, the better it will be for the public; and by introducing the diſtilling of herbs, there will be leſs occaſion for uſing of Wheat.

MENTHA CATARIA. See Nepeta.

MENTZELIA. Plum. Nov. Gen. Plant. 40. tab. 6. Lin. Gen. Plant. 595.

The name was given to this plant by Father Plumier, who diſcovered it in the French ſettlements in America, in honour of Dr. Mentzelius, who was phyſician to the Elector of Brandenburgh, and who publiſhed an Index of plants in Latin, Greek, and High Dutch.

The Characters are,

The flower hath a ſpreading empalement cut into five parts, which ſits upon a long cylindrical germen. It hath five petals which ſpread open, and are a little longer than the empalement, and many erect briſtly ſtamina, terminated by ſingle ſummits. From the long cylindrical germen which is ſituated under the flower, ariſes a briſtly ſtyle the length of the petals, crowned by a ſingle ſtigma. The germen afterward turns to a cylindrical long capſule with one cell, containing many ſmall ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's thirteenth claſs, which includes thoſe plants whoſe flowers have many ſtamina and one ſtyle.

We know but one Species of this genus, viz.

Mentzelia (*Aſpera.*) Hort. Cliff. 492. Plumier titles it Mentzelia foliis & fructibus aſperis. Nov. Gen. Plant. 41. *Mentzelia with prickly leaves and fruit.*

This plant grows plentifully at La Vera Cruz, from whence the ſeeds were ſent to England by the late Dr. William Houſtoun, which have ſucceeded in the phyſic garden at Chelſea.

This plant is annual; it riſes with a ſlender ſmooth ſtalk, which is ſtiff, and becomes a little woody, riſing more than three feet high, branching out alternately at diſtances; the branches are diſtorted, and run into one another; theſe are garniſhed with leaves ſhaped like the point of an halbert, ſtanding alternately on the branches, upon ſhort foot-ſtalks; they are covered with ſhort hooded prickles, which faſten themſelves into the clothes of thoſe who rub againſt them; and thoſe parts of the branches eaſily ſeparate from the plants, and adhere to the clothes in like manner as the ſeeds of Clivers. The flowers come out ſingly from the joints of the ſtalk, reſting upon a cylindrical germen, which is near an inch in length, narrow at the baſe, but widens upward to the top. Upon the top of it comes out the empalement, which is ſpread open after the ſame manner as thoſe of the Onagra; then the petals of the flower ſpread open upon the empalement; they are of a pale yellow colour, and longer than the empalement. In the middle ariſes a great number of ſtamina which are erect, and are terminated by ſingle ſummits; from the germen ariſes a ſingle ſtyle, which is as long as the petals, crowned by a ſingle ſtigma. The germen afterward turns to a long cylindrical capſule, armed with the like prickles as the leaves, which alſo faſten themſelves to the clothes of thoſe who rub againſt them; theſe have but one cell, which is filled with ſmall ſeeds.

As this is an annual plant, which periſhes ſoon after the ſeeds are ripe, therefore the ſeeds muſt be ſown on a hot-bed early in the ſpring, that the plants may be brought forward early in the ſeaſon, otherwiſe they will not produce ripe ſeed in this country. When the plants are come up about an inch high, they ſhould be each tranſplanted into a ſeparate halfpenny pot filled with light rich earth, and plunged into a hot-bed of tanners bark, being careful to ſhade them from the ſun until they have taken new root; after which time they muſt be conſtantly watered every other day in warm weather, and ſhould have freſh air every day admitted to them, in proportion to the warmth of the ſeaſon, and the heat of the bed in which they are plunged. In about ſix weeks or two months after tranſplanting, if the plants have made a good progreſs, they will have filled the pots with their roots, when they ſhould be ſhifted into larger pots, which muſt be filled with light rich earth, and then plunged into the bark-bed in the ſtove, that they may have room to grow in height, obſerving, as before, to water them duly, as alſo to admit freſh air to them every day in warm weather: with this management the plants will riſe to the height of three feet, and will produce ripe ſeeds the latter end of Auguſt or the beginning of September.

MENYANTHES, is the Trifolium Paluſtre, or Bog Bean.

This plant is common upon boggy places in divers parts of England, but is never cultivated in gardens; for which reaſon I ſhall not trouble the reader with any farther account of it, except the taking notice, that this plant is at preſent in great eſteem, being thought an excellent remedy for the rheumatiſm, gout, and many other diſorders. It is frequently called Bog Bean, or Marſh Trefoil, in the markets, and grows plentifully on bogs in many parts of England, where it is gathered and brought to ſupply the markets.

MERCURIALIS. Tourn. Inſt. R. H. 534. tab. 308. Lin. Gen. Plant. 998. [This plant takes its name from Mercury, becauſe the ancients had a notion, that the God Mercury brought this plant into uſe.] Mercury; in French, *Mercuriale.*

The Characters are,

It is male and female in different plants; the male flowers have a ſpreading empalement, which is cut into three concave ſegments; theſe have no petals, but have nine or twelve erect hairy ſtamina, crowned by globular twin ſummits. The female flowers have no petals, but have two awl-ſhaped acute-pointed nectariums; to each of theſe there is a ſingle broad germen, impreſſed with a furrow between them; theſe roundiſh compreſſed germen have a prickly furrow on each ſide, and ſupport two reflexed prickly ſtyles, crowned by acute reflexed ſtigmas. The germen afterward turns to a twin capſule ſhaped like the ſcrotum, having two cells, each containing one roundiſh ſeed.

This genus of plants is ranged in the eighth ſection of Linnæus's twenty-ſecond claſs, which includes thoſe plants whoſe male flowers grow on different plants from the fruit, and have nine ſtamina in each.

The Species are,

1. Mercurialis (*Annua*) caule brachiato, foliis glabris. Hort. Cliff. 461. *Mercury with a branching ſtalk and ſmooth leaves.* Mercurialis ſpicata & teſticulata mas & fœmina. C. B. P. 121. *Mercury with ſpiked and teſticulated flowers, which are both male and female, called French Mercury.*
2. Mercurialis (*Perennis*) caule ſimpliciſſimo, foliis ſcabris. Hort. Cliff. 461. *Mercury with a ſingle ſtalk and rough leaves.* Mercurialis montana ſpicata & teſticulata. C. B. P. 122. *Mountain Mercury, or Dogs Mercury, with ſpiked and teſticulated flowers.*
3. Mercurialis (*Tomentoſa*) caule ſubfruticoſo, foliis tomentoſis. Hort. Cliff. 461. *Mercury with a ſtalk ſomewhat ſhrubby, and woolly leaves.* Mercurialis fruticoſa incana, ſpicata & teſticulata. Tourn. Inſt. R. H. 534. *Shrubby hoary Mercury, having ſpiked and teſticulated flowers.*

The firſt ſort is commonly called French Mercury, from whence it might have been brought into England; for although it is now become a weed in gardens and upon dunghills, yet it is ſeldom found growing at a diſtance from habitations. This is an annual plant, with a branching ſtalk about a foot high, garniſhed with ſpear-ſhaped leaves about an inch and a half long, indented on their edges, of a pale or yellowiſh green colour. The male plants have ſpikes of herbaceous flowers growing on the top of the ſtalks, theſe fall ſoon; but the female plants, which have teſticulated flowers proceeding from the ſide of the ſtalks, are ſucceeded by ſeeds, which, if permitted to ſcatter, will produce plenty of plants of both ſexes. The leaves and ſtalks of this plant are uſed in medicine, and are reckoned aperitive and mollifying.

The ſecond ſort grows under hedges and in woods in moſt parts of England. This hath a perennial root, which creeps in the ground; the ſtalks are ſingle and without branches, riſing ten or twelve inches high, garniſhed with rough leaves, placed by pairs at each joint; they are of a dark green colour, and indented on their edges; theſe have their male flowers growing in ſpikes upon different plants, from thoſe which produce ſeeds.

This hath a poiſonous quality, there have been many late inſtances of it, where people in the ſpring of the year, when there has been a ſcarcity of greens, have boiled the leaves of this, and have ſuffered greatly by eating them.

The third ſort grows naturally in the ſouth of France, in Spain, and Italy. This riſes with a ſhrubby branching ſtalk a foot and a half high, garniſhed with oval leaves placed by pairs, which are covered with a white down on both ſides. The male flowers grow in ſhort ſpikes from the ſide of the ſtalks, upon different plants from the fruit, which are teſticulated and hoary. If the ſeeds of theſe are permitted to ſcatter, the plants will come up the following ſpring; and if the ſeeds are ſown, it ſhould be performed in the autumn, for thoſe which are ſown in the ſpring ſeldom grow the ſame year. This plant ſhould have a warm ſituation and a dry rubbiſhy ſoil, in which it will live three or four years, but in hard froſt theſe plants are frequently killed.

MESEMBRYANTHEMUM. Dill. Gen. 9. Hort. Elth. 179. Ficoides. Tourn. Act. R. Par. 1705. Fig Marygold.

The Characters are,

The flower hath a permanent ſpreading empalement of one leaf, which is cut at the top into five acute parts. It hath one petal, which is cut into many linear ſegments almoſt to the bottom, and ranged in ſeveral ſeries, but are joined together at their baſe; within theſe are ranged a great number of hairy ſtamina, terminated by incumbent ſummits. Under the flower is ſituated an obtuſe five-cornered germen, ſupporting ſometimes five, and often ten or more ſtyles, which are reflexed, and crowned by ſingle ſtigmas. The germen afterward becomes a roundiſh fleſhy fruit, having as many cells as there are ſtyles, filled with ſmall ſeeds.

This genus of plants is ranged in the fourth ſection of Linnæus's twelfth claſs, which includes thoſe plants whoſe flowers have from twenty to thirty ſtamina inſerted in the empalement, and five ſtyles.

The Species are,

1. Mesembryanthemum (*Nodiflorum*) foliis alternis teretiuſculis obtuſis ciliatis. Hort. Upſal. 129. *Meſembryanthemum with taper, obtuſe, hairy leaves, placed alternately.* Ficoides Neapolitana, flore candido. H. L. *Fig Marygold of Naples with a white flower, or Egyptian Kali.*
2. Mesembryanthemum (*Cryſtallinum*) foliis alternis ovatis papuloſis undulatis. Hort. Cliff. 216. *Meſembryanthemum with oval, obtuſe, waved leaves placed alternately.* Ficoides Africana, folio plantaginis undulato, micis argenteis adſperſo. Tourn. Act. R. Par. 1705. *African Fig Marygold, with a waved Plantain leaf, marked with ſilvery ſpots, commonly called the Diamond Ficoides, or Diamond Plant.*
3. Mesembryanthemum (*Geniculiflorum*) foliis ſemiteretibus papuloſis diſtinctis floribus ſeſſilibus axillaribus. Lin. Sp. Plant. 481. *Meſembryanthemum with half taper leaves, and flowers ſitting cloſe to the wings of the ſtalks.* Ficoides Capenſe, folio tereti, flore albido. Pet. Gaz. 78. fol. 3. *Fig Marygold of the Cape, with a taper leaf and a whitiſh flower.*
4. Mesembryanmthemum (*Noctiflorum*) foliis ſemicylindraceis, impunctatis diſtinctis, floribus pedunculatis calycibus quadrifidis. Lin. Sp. Plant. 481. *Meſembryanthemum with almoſt cylindrical leaves, and quadrifid foot-ſtalks to the flowers.* Ficoides Africana, erecta, arboreſcens, lignoſa, flore radiato, primo purpureo, dein argenteo, interdiu clauſo, nocte aperto. Boerh. Ind. alt. 1. 290. *Upright, ligneous, tree Fig Marygold of Africa, with a radiated flower, which is at firſt purple, afterward ſilvery, ſhut in the day, and open at night.*
5. Mesembryanthemum (*Splendens*) foliis ſemiteretibus impunctatis recurvis diſtinctis congeſtis, calycibus

terminalibus digitiformibus. Lin. Sp. 689. *Meſembryanthemum with taper, unſpotted, recurved, diſtinct leaves in cluſters, whoſe empalement is finger-ſhaped.*

6. Mesembryanthemum (*Umbellatum*) foliis ſubulatis, ſcabrido-punctatis connatis apice patulo, caule erecto, corymbo trichotoma. Lin. Sp. Plant. 481. *Meſembryanthemum with awl-ſhaped leaves which join, having rough ſpots, an erect ſtalk, and a corymbus of flowers at the triple diviſion of the ſtalk.* Ficoides Africana erecta teretifolia, floribus albis umbellatis. Par. Bat. 166. *Upright African Fig Marygold, with a taper leaf, and white flowers growing in umbels.*

7. Mesembryanthemum (*Calamiforme*) acaule foliis ſubteretibus adſcendentibus impunctatis connatis, floribus octagynis. Lin. Sp. Plant. 481. *Meſembryanthemum without a ſtalk, almoſt taper leaves which join at their baſe, and flowers having eight ſtyles.* Ficoides Capenſis humilis, cepææ folio, flore ſtamineo. Brad. Suec. p. 10. fol. 19. *Low Fig Marygold of the Cape, with an Onion leaf, and a ſtamineous flower.*

8. Mesembryanthemum (*Tripolium*) foliis alternis lanceolatis planis impunctatis caulibus laxis ſimplicibus calycibus pentagonis. Hort. Cliff. 217. *Meſembryanthemum with plain ſpear-ſhaped leaves which are not ſpotted, a ſingle weak ſtalk, and a five-cornered empalement.* Ficoides Africana, procumbens, tripolii folio, flore argenteo. Hort. Chelſ. *Trailing African Fig Marygold, with a Tripolium leaf and a ſilvery flower.*

9. Mesembryanthemum (*Bellidiflorum*) acaule, foliis triquetris linearibus impunctatis apice trifariàm dentatis. Hort. Cliff. 218. *Meſembryanthemum without a ſtalk, having narrow, three-cornered, unſpotted leaves, marked with three indentures at their points.* Ficoides Capenſis humilis, folio triangulari in ſummitatem dentato, flore minore purpuraſcente. Brad. Suec. p. 9. tab. 18. *Dwarf Marygold of the Cape, with a triangular leaf indented at the top, and a ſmaller purpliſh flower.*

10. Mesembryanthemum (*Subulatum*) acaule foliis ſubulatis triquetris dorſo ſupernè ſerratis. *Meſembryanthemum without a ſtalk, and awl-ſhaped three-cornered leaves, whoſe back part is ſawed toward the top.*

11. Mesembryanthemum (*Deltoides*) foliis deltoidibus triquetris dentatis impunctatis diſtinctis. Hort. Cliff. 218. *Meſebryanthemum with three-cornered indented leaves, which are ſhaped like the Greek delta, without ſpots, and diſtinct.* Ficoides Africana, folio triangulari craſſo, brevi, glauco, ad tres margines aculeato. Boerh. Ind. alt. 1. 290. *African Fig Marygold, with a ſhort, thick, gray, triangular leaf, with prickles on the three edges.*

12. Mesembryanthemum (*Cauleſcens*) cauleſcens, foliis deltoidibus, lateribus minimè dentatis. *Stalky Meſembryanthemum, with leaves ſhaped like the Greek delta, whoſe ſides are a little indented.* Ficoides Africana, folio triangulari glauco, breviſſimo, craſſiſſimo, margine non ſpinoſo. Boerh. Ind. alt. 1. 290. *African Fig Marygold, with very thick, ſhort, triangular, gray leaves, having no ſpines on their edges.*

13. Mesembryanthemum (*Barbatum*) foliis ſubovatis papuloſis diſtinctis apice barbatis. Hort. Cliff. 216. *Meſembryanthemum with almoſt oval leaves, having diſtinct bladders bearded at their points.* Ficoides ſeu ficus aizoides Africana, folio variegato aſpero, ad apicem ſtella ſpinoſa armato. Boerh. Ind. alt. 1. p. 291. *African Fig Marygold, with a rough variegated leaf, whoſe point is armed with ſpines in form of a ſtar.*

14. Mesembryanthemum (*Stellatum*) caulibus decumbentibus, foliis teretibus papuloſis apice barbatis. *Meſembryanthemum with decumbent ſtalks and taper bladdered leaves, whoſe points are bearded like a ſtar.* Ficoides Capenſis fruteſcens, folio tumido, extremitate ſtellatâ, flore purpureo. Brad. Suec. Dec. 1. tab. 6. *Shrubby Fig Marygold of the Cape, with a ſtar-pointed tumid leaf, and a purple flower.*

15. Mesembryanthemum (*Hiſpidum*) foliis cylindricis papuloſis diſtinctis, caule hiſpido. Lin. Sp. Plant. 482. *Meſembryanthemum with a prickly ſtalk, and deflexed cylindrical leaves with pulpy bladders.* Ficoides Afra, fruticoſa, caule lanugine argenteâ ornato, folio tereti, parvo, longo, guttulis argenteis quaſi ſcabro, flore violaceo. Boerh. Ind. alt. 1. 291. *African ſhrubby Fig Marygold, having ſtalks adorned with ſilvery down, and long, ſmall, taper leaves, ſpotted as it were with ſilvery drops, and a Violet-coloured flower.*

16. Mesembryanthemum (*Villoſum*) caule foliiſque pubeſcentibus. Hort. Cliff. 217. *Meſembryanthemum whoſe ſtalks and leaves are garniſhed with downy hairs.*

17. Mesembryanthemum (*Scabrum*) foliis ſubulatis diſtinctis ſubtus undique muricatis, calycibus muticis. Hort. Cliff. 219. *Meſembryanthemum with awl-ſhaped leaves, which are diſtinct, every where rough on their under ſide, and chaffy empalements.* Ficoides Afra, folio triangulari viridi longo aſpero, flore violaceo. Boerh. Ind. alt. 290. *African Fig Marygold, with a long, green, rough, triangular leaf, and a Violet-coloured flower.*

18. Mesembryanthemum (*Uncinatum*) articulis caulinis terminatis in folia connata acuminata ſubtus dentata. Hort. Cliff. 218. *Meſembryanthemum whoſe joints of the ſtalks are terminated by acute-pointed leaves, which are joined at their baſe, and indented on their under ſide.* Ficoides Afra, folio triangulari glauco, perfoliato, breviſſimo, apice ſpinoſo. Boerh. Ind. alt. 290. *African Fig Marygold, with a ſhort, perfoliated, triangular leaf, whoſe point is prickly, commonly called Buckſhorn Ficoides.*

19. Mesembryanthemum (*Perfoliatum*) perfoliatum, foliis majoribus, apicibus triacanthis. Hort. Elth. 251. *Perfoliate Meſembryanthemum with larger leaves, whoſe points have three thorns.* Ficoides Africana fruteſcens perfoliata, folio triangulari glauco punctato, cortice lignoſo candido tenui. Tourn. Act. Par. 1705. *Shrubby, perfoliate, African, Fig Marygold, with a triangular, gray, ſpotted leaf, and a thin, white, ligneous bark, commonly called Stagſhorn Ficoides.*

20. Mesembryanthemum (*Spinoſum*) foliis tereti-triquetris punctatis diſtinctis ſpinis ramoſis. Hort. Cliff. 216. *Meſembryanthemum with taper three-cornered leaves, which have diſtinct ſpots and branching ſpines.* Ficoides Africana, aculeis longiſſimis & foliolis naſcentibus ex foliorum alis. Tourn. Act. R. Par. 1705. *African Fig Marygold with long ſpines, and ſmaller leaves ariſing from the wings of the leaves.*

21. Mesembryanthemum (*Tuberoſum*) foliis ſubulatis pappiloſis, diſtinctis apice patulis radice capitatâ. Hort. Cliff. 216. *Meſembryanthemum with awl-ſhaped pimply leaves, and a headed root.* Ficoides Africana, folio triangulari recurvo, floribus umbellatis obſoleti coloris, externè purpureis. Tourn. Act. Par. 1705. *African Fig Marygold with a triangular recurved leaf, and umbellated flowers of a dark colour, which are purple on their outſide.*

22. Mesembryanthemum (*Tenuifolium*) foliis ſubulatis ſemiteretibus glabris, diſtinctis internodio longioribus. Hort. Cliff. 216. *Meſembryanthemum with awl-ſhaped, half-taper, ſmooth, diſtinct leaves, whoſe joints are farther diſtant.* Ficoides Capenſis humilis, teretifolia, flore coccineo. Brad. Suec. p. 13. *Low Fig Marygold of the Cape, with a taper leaf and a ſcarlet flower.*

23. Mesembryanthemum (*Stipulaceum*) foliis ſubtriquetris compreſſis incurvatis punctatis diſtinctis congeſtis baſi marginatis. Lin. Sp. 693. *Meſembryanthemum with three-cornered, compreſſed, incurved leaves, having diſtinct ſpots, whoſe baſe are bordered and cluſtered.* Meſembryanthemum fruteſcens, flore purpureo rariore. Hort. Elth. tab. 209.

24. Mesembryanthemum (*Craſſifolium*) foliis ſemicylindricis impunctatis connatis, apice triquetris caule repente ſemicylindricis. Hort. Cliff. 217. *Meſembryanthemum with a creeping cylindrical ſtalk, cylindrical ſmooth leaves, joining at their baſe, whoſe points are three-cornered.* Ficoides Africana reptans, folio triangulari, flore ſaturatè purpureo. Brad. Suec. p. 16. tab. 38. *Creeping African Fig Marygold with a green triangular leaf, and deep purple-coloured flower.*

25. Mesembryanthemum (*Falcatum*) foliiis ſub-acinaciformibus incurvis punctatis diſtinctis ramis teretibus. Hort. Cliff. 219. *Meſembryanthemum with diſtinct, ſmooth, falchion-ſhaped leaves, and taper branches.* Ficoides Afra folio triangulari enſiformi breviſſimo,

flore dilutè purpuraſcente filamentoſo. Brad. Suec. Dec. 5. tab. 42. *African Fig Marygold with a triangular, cimeter-ſhaped, ſhort leaf, and a pale purpliſh flower.*

26. **MESEMBRYANTHEMUM** (*Glomeratum*) foliis teretiuſculis compreſſis punctatis, caule paniculato multifloro. Lin. Sp. 694. *Meſembryanthemum with taper, compreſſed, ſpotted leaves, and a panicled ſtalk with many flowers.* Meſembryanthemum falcatum minus, flore carneo minore. Hort. Elth. tab. 213.

27. **MESEMBRYANTHEMUM** (*Edule*) foliis æquilateri-triquetris acutis ſtrictis impunctatis connatis carina ſubſerratis, caule ancipiti. Lin. Sp. 695. *Meſembryanthemum with equilateral, acute, unſpotted leaves joined at their baſe, whoſe keel are ſawed.* Ficoides ſeu ficus aizoides Africana major procumbens, triangulari folio, fructu maximo eduli. H. L. 244. *Greater trailing African Fig Marygold, with a triangular leaf and a large eatable fruit.*

28. **MESEMBRYANTHEMUM** (*Bicolorum*) foliis ſubulatis lævibus punctatis diſtinctis caule fruteſcente corollis bicoloribus. Lin. Sp. Plant. 695. *Meſembryanthemum with awl-ſhaped ſmooth leaves, which have different ſpots, a ſhrubby ſtalk, and the flower of two colours.* Ficoides Capenſis fruteſcens, folio tereti punctato, petalis luteis. Brad. Suec. 1. p. 8. tab. 7. *Shrubby Fig Marygold of the Cape, with a taper leaf having punctures, and yellow petals.*

29. **MESEMBRYANTHEMUM** (*Acinaciforme*) foliis acinaciformibus impunctatis connatis, angulo carinali ſcabris, petalis lanceolatis. Lin. Sp. 695. *Meſembryanthemum with ſharp, three-cornered, unſpotted leaves, joined at their baſe, whoſe keel are rough, and ſpear-ſhaped petals of the flower.* Ficoides Africana folio longo triangulari incurvo, caule purpureo. Tourn. Act. Par. 1705. *African Fig Marygold with a long triangular leaf, which is incurved, and a purple ſtalk.*

30. **MESEMBRYANTHEMUM** (*Loreum*) foliis ſemicylindricis recurvis congeſtis baſi interiore gibbis connatis, caule pendulo. Lin. Sp. 694. *Meſembryanthemum with cylindrical recurved leaves, whoſe baſe are cluſtered and join, and a pendulous ſtalk.* Meſembryanthemum loreum. Hort. Elth. tab. 200.

31. **MESEMBRYANTHEMUM** (*Serratum*) foliis ſubulatis triquetris punctatis diſtinctis angulo carinali retrorſum ſerratis. Lin. Sp. 696. *Meſembryanthemum with awl-ſhaped leaves having diſtinct ſpots, and the angle of the keel ſawed.* Meſembryanthemum ſerratum flore acetabuliformi luteo. Hort. Elth. tab. 192.

32. **MESEMBRYANTHEMUM** (*Tuberculatum*) acaule foliis ſemicylindricis connatis externè tuberculatis. Hort. Cliff. 219. *Meſembryanthemum without a ſtalk, and cylindrical leaves which have tubercles on their outſides, and are joined at their baſe.* Ficoides Afra, folio triangulari, longo, ſucculento, caulibus rubris. Boerh. Ind. alt. 290. *African Fig Marygold with a long, triangular, ſucculent leaf, and red ſtalks.*

33. **MESEMBRYANTHEMUM** (*Veruculatum*) foliis triquetro-cylindricis acutis connatis arcuatis impunctatis diſtinctis. Hort. Cliff. 220. *Meſembryanthemum with three-cornered cylindrical leaves which are connected at their baſe, bowed and ſmooth.* Ficoides Afra arboreſcens, folio tereti glauco, apice purpureo craſſo. Boerh. Ind. alt. 291. *African Tree Fig Marygold, with a taper gray leaf, having a thick purple top.*

34. **MESEMBRYANTHEMUM** (*Glaucum*) foliis triquetris acutis, punctatis diſtinctis calycinis foliolis ovato-cordatis. Lin. Sp. 696. *Meſembryanthemum with acute three-cornered leaves marked with punctures, and oval heart-ſhaped empalements.* Ficoides Afra caule lignoſo, erecta, folio triangulari enſiformi ſcabro, flore luteo magno. Boerh. Ind. alt. 289. *African Fig Marygold with an erect ligneous ſtalk, a triangular, cimeter-ſhaped, rough leaf, and a large yellow flower.*

35. **MESEMBRYANTHEMUM** (*Corniculatum*) foliis triquetro-ſemicylindricis ſcabrido-punctatis, ſupra baſin linea elevatis connatis. Lin. Sp. 697. *Stalky Meſembryanthemum with three-cornered, ſemicylindrical, rough, ſpotted leaves, which are connected at their baſe.* Ficoides Afra triangulari longiſſimo, marginibus obtuſioribus, flore amplo, intus pallidè luteo, extus lineâ rubrâ longâ picto. Boerh. Ind. alt. 289. *African Fig Marygold with a long triangular leaf, obtuſer borders, and a large flower of a pale yellow within, and marked with a long red ſtreak on the outſide.*

36. **MESEMBRYANTHEMUM** (*Expanſum*) foliis planiuſculis lanceolatis impunctatis patentibus diſtinctis oppoſitis alternatiſque remotis. Lin. Sp. 697. *Meſembryanthemum with plain, ſpear-ſhaped, unſpotted leaves, which ſpread diſtinctly, and are oppoſite and alternate at a diſtance.* Ficoides Africana humifuſa, folio triangulari longiore glauco, flore flaveſcente. Tourn. Acad. R. Par. 1705. *Trailing African Fig Marygold, with a longer, gray, triangular leaf, and a yellowiſh flower.*

37. **MESEMBRYANTHEMUM** (*Micans*) foliis ſubulatis triquetris punctatis diſtinctis, caule ſcabro. Lin. Sp. 696. *Meſembryanthemum with three-cornered awl-ſhaped leaves, which are diſtinctly ſpotted, and a rough ſtalk.* Meſembryanthemum micans, flore Phœnicio, filamentris atris. Hort. Elth. tab. 215.

38. **MESEMBRYANTHEMUM** (*Tortuoſum*) foliis planiuſculis oblongo-ovatis ſubpapilloſis confertis connatis, calycibus tryphyllis bicornibus. Lin. Sp. 697. *Meſembryanthemum with plain, oblong, oval leaves joining at their baſe, and a three-leaved empalement with two horns.* Ficoides Capenſis procumbens aleæ folio, flore albo medio croceo. Brad. Suec. Dec. 2. p. 7. tab. 16. *Trailing Fig Marygold of the Cape, with an Olive leaf, and a white flower of a Saffron colour in the middle.*

39 **MESEMBRYANTHEMUM** (*Ringens*) ſubacaule, foliis ciliato-dentatis. Lin. Hort. Cliff. 218. *Meſembryanthemum with a ſhort ſtalk, and leaves having hairy indentures.* Ficoides Capenſis humilis, folio triangulari prope ſumitatem dentato, flore luteo. Brad. Suec. Dec. 2. p. 8. tab. 17. *Low Fig Marygold of the Cape, with a triangular leaf indented toward the top, and a yellow flower, commonly called Dogs Chap Ficoides.*

40. **MESEMBRYANTHEMUM** (*Roſtratum*) acaule, foliis ſemicylindricis connatis externe tuberculatis. Lin. Sp. 696. *Meſembryanthemum without a ſtalk, having cylindrical leaves joined at their baſe, and tubercles on the outſide.* Ficoides Afra folio triangulari, enſiformi craſſo brevi, ad margines laterales multis majoribus ſpinis aculeato. Martyn. Cent. 30. tab. 30. *African Fig Marygold, with a triangular, cimeter-ſhaped, ſhort, thick leaf, whoſe ſide borders have many large ſpines, commonly called Cats Chap Ficoides.*

41. **MESEMBRYANTHEMUM** (*Dolabriforme*) foliis dolabriformibus punctatis. Hort. Cliff. 219. *Meſembryanthemum with ax-ſhaped ſpotted leaves.* Ficoides Capenſis humilis foliis cornua cervi referentibus, petalis luteis, noctiflora. Brad. Suec. 1. p. 11. tab. 10. *Low Fig Marygold of the Cape, with leaves like a ſtag's horn, yellow petals, and a flower opening at night.*

42. **MESEMBRYANTHEMUM** (*Difforme*) foliis difformibus punctatis connatis. Prod. Leyd. 287. *Meſembryanthemum with deformed leaves.* Ficoides Afra foliis latiſſimis craſſimis lucidis, difformibus. Boerh. Ind. alt. 292. *African Fig Marygold, with very broad, thick, ſhining, deformed leaves.*

43. **MESEMBRYANTHEMUM** (*Lucidnm*) acaule foliis linguiformibus lucidis imarginatis. *Meſembryanthemum without a ſtalk, and tongue-ſhaped lucid leaves, indented at the top.* Ficoides Afra acaulos, foliis latiſſimis craſſis lucidis conjugatis, flore aureo ampliſſimo. Tourn. Acad. R. Scien. 1705. *African Fig Marygold without a ſtalk, broad, thick, ſhining leaves growing by pairs, and a very large yellow flower.*

44. **MESEMBRYANTHEMUM** (*Linguiforme*) acaule foliis linguiformibus altero margine craſſioribus impunctatis. Lin. Sp. 699. *Meſembryanthemum without a ſtalk, very broad tongue-ſhaped leaves, one edge being thicker than the other, and without ſpots.* Ficoides Afra acaulos, foliis latiſſimis craſſiſſimis, lucidis conjugatis, flore aureo amplo, pedunculo brevi. Boerh. Ind. alt. 292. *African Fig Marygold having no ſtalk, very broad, thick, ſhining leaves placed by pairs, and a large golden flower with a ſhort foot-ſtalk.*

45. **MESEMBRYANTHEMUM** (*Albidum*) acaule foliis triquetris. *Meſembryanthemum having no ſtalk, and gray, entire, three-cornered leaves.* Meſembryanthemum foliis robuſtis albicantibus. Hort. Elth. 243. *Meſembryanthemum with ſtrong whitiſh leaves.*

46. Meſembryanthemum (*Pugioneforme*) foliis alternis ſubulatis triquetris longiſſimis impunctatis. Hort. Cliff. 216. *Meſembryanthemum with alternate, awl-ſhaped, three-cornered leaves, which are very long, without ſpots.* Ficoides Capenſis, caryophylli folio, flore aureo ſpecioſo. Brad. Suec. Dec. 2. p. 5. tab. 14. *Fig Marygold of the Cape, with a Clove Gilliflower leaf, and a beautiful golden-coloured flower.*

Theſe plants are moſt of them natives of the Cape of Good Hope, from whence their ſeeds were firſt brought to Holland, and the plants raiſed in many of their curious gardens, and have ſince been communicated to moſt parts of Europe; theſe were at firſt titled Chryſanthemum by the old botaniſts, but afterward they were titled Ficoides by Herman and Tournefort, from their capſules being ſhaped like little Figs; afterward they had this title of Meſembryanthemum applied to them, which ſignifies a flower opening in the middle of the day, which is what moſt of the ſpecies do; there are three or four of them which open in the evening, and are cloſed all the day; theſe have been ſeparated from the others by ſome, and have had the title of Nycterianthemum applied to them, from their flowers being expanded in the night; but as they all agree in the characters which diſtinguiſh the genus, they ſhould by no means be ſeparated.

Moſt of the plants of this genus have beautiful flowers, which appear at different ſeaſons of the year; ſome of them flower early in the ſpring, others in ſummer, ſome in the autumn; and there are others which flower in winter; and many of them produce their flowers in ſuch quantity, as that when they are expanded, the plants are entirely covered with them; they have all of them thick ſucculent leaves, but ſome of the ſpecies are much more ſo than others, and the figures of their leaves vary ſo much in the ſeveral ſpecies, that they afford an agreeable variety when they are not in flower.

To deſcribe all the ſpecies which are here mentioned, would ſwell this work too much, and as their titles are ſhort deſcriptions of the ſpecies, I ſhall not enlarge more on that head, but proceed to their culture.

All the ſorts here mentioned are perennial plants except the two firſt, which are annual. The perennial ſorts are eaſily propagated by cuttings during any of the ſummer months; ſuch of them as have ſhrubby ſtalks and branches, very readily take root when planted in a bed of light ſoil, and covered either with mats or glaſſes, but when they are covered with the latter, they muſt be ſhaded every day when the ſun is warm; theſe cuttings of the ſhrubby ſorts need not be cut from the plant more than five or ſix days before they are planted, during which time they ſhould be laid in a dry room, not too much expoſed to the ſun, that the part which was ſeparated from the old plants may heal over and dry before they are planted, otherwiſe they are apt to rot; theſe may be planted at about three inches diſtance from each other, and the earth preſſed cloſe to them, but none of their leaves ſhould be buried in the ground, for as they abound with moiſture, ſo if they are covered with the earth, it will cauſe them to rot, and that often deſtroys the cuttings; therefore when the cuttings are taken from the old plants, they ſhould be diveſted of their lower leaves, ſo far as may be neceſſary, to allow a naked ſtalk of ſufficient length for planting.

When the cuttings are planted, it will be neceſſary to give them a little water, to ſettle the ground about them, but it ſhoold be done with caution, for too much wet will ſpoil them; if theſe are ſhaded every day from nine or ten o'clock till three or four, when the ſun is warm, it will prevent the ground from drying too faſt, ſo that the cuttings need not be watered oftener than once in a week; but if there ſhould happen ſome gentle ſhowers of rain, it will be proper to take off their covers, and let them receive it, but they ſhould be ſcreened from hard rains. The cuttings thus managed will have put out good roots in about ſix weeks, when they ſhould be carefully taken up, and each planted in a ſeparate ſmall pot filled with light ſandy earth, and then placed in a ſhady ſituation, giving them a little water to ſettle the earth to their roots; in this place they may remain about ten days or a fortnight, by which time they will have taken good root, and may be removed to a ſheltered place, where they may have more ſun, in which they may remain till autumn; during the ſummer months, theſe may be watered twice, or in very hot weather, three times a week, but it muſt not be given them in too great plenty; but as the ſun declines in autumn, they ſhould not have it oftener than once a week, for if they are often ſupplied with it, the plants will grow luxuriant; their leaves and branches will be ſo replete with moiſture, that the early froſts in the autumn will deſtroy them; whereas when they are kept dry, their growth will be ſtinted; ſo that they will be hardy enough to reſiſt ſmall froſts, but there muſt be care taken that they do not ſhoot their roots through the holes of the pots into the ground, for when they do, the plants will grow very luxuriant; and when the pots are removed, and thoſe roots are torn off, their leaves and branches will ſhrink, ſo will not recover it in a long time, if ever; to prevent which, the pots ſhould be removed every fortnight, and where the roots are beginning to come through the pots, they ſhould be cut off. The ſorts which grow very freely ſhould be ſhifted three times in the ſummer, to pare off their roots, and keep them within compaſs, and theſe ſhould never be planted in rich earth for the reaſons before given; for if the earth is freſh, there will require no dung or other compoſt, unleſs it is ſtrong, in which caſe ſea ſand, or lime rubbiſh, will be a good mixture; the quantity of either muſt be in proportion to the ſtiffneſs of the ground, always being careful to render it ſo light, as that the wet may eaſily paſs off.

We next proceed to treat of thoſe ſorts, whoſe ſtalks and leaves are very ſucculent. The cuttings of theſe ſhould be taken from the plants ten days or a fortnight before they are planted, that they may have time for their wounded part to heal over and dry; the lower leaves of theſe ſhould alſo be ſtripped off, that their naked ſtalks may be of a ſufficient length for planting. As theſe are moſtly plants of humble growth, ſo if their ſtalks are diveſted of their leaves an inch and a half, it will be ſufficient. The cuttings of theſe ſorts require to be covered with glaſſes, to keep off the wet; they muſt alſo have leſs water than the other, but in other particulars require the ſame treatment. The roots of theſe do not ſpread and extend ſo much as thoſe of the other, ſo will not require to be ſhifted oftener than twice a year at moſt; they muſt alſo be kept in ſmall pots to confine their roots; the earth in which they are planted ſhould be rather light and not rich. During the ſummer ſeaſon they muſt not have too much wet, and in the winter they muſt have but little water. If theſe ſucculent ſorts are placed in an open airy glaſs-caſe in winter, where they may have free air admitted to them in plenty in mild weather, and ſcreened from the froſt, they will thrive much better than when they are more tenderly treated. The other ſhrubby kinds may be ſheltered in winter under a common frame, where, if they are protected from froſt and wet, it is all they require; for the hardier theſe are treated, the greater quantity of flowers they will produce: and ſome of the ſorts are ſo hardy, as to live abroad when planted cloſe to a good aſpected wall, and in a poor dry ſoil; ſo that where there is room to diſpoſe them againſt a wall, and the border is raiſed with lime rubbiſh to prevent their rooting deep and growing luxuriant, they may be preſerved through the winter with very little ſhelter, and theſe will flower much better than thoſe under cover.

The firſt ſort grows naturally in Egypt, where they cut up the plants, and burn them for pot-aſh; and this is eſteemed as the beſt ſort for making hard ſope, and the beſt ſort of glaſs.

This is an annual plant, which does not perfect ſeeds in England; for when it is placed in the ſtove, or kept in the hot-bed, their ſtalks grow long and ſlender, ſo are not productive of flowers; and thoſe which are raiſed in hot-beds, and afterward expoſed in the open air, will flower pretty freely, but do not perfect their ſeeds. As this plant will thrive in South Carolina as well as in its native ſoil, ſo it might turn to the advantage of that colony, and likewiſe become beneficial to the public, if the inhabitants could be prevailed on to cultivate this plant.

The ſecond ſort is annual; this is a native at the Cape of Good Hope. It is propagated for the oddneſs of its leaves and ſtalks, which are cloſely covered over with pellucid pimples full of moiſture, which, when the ſun ſhines on the plants, they reflect the light, and appear like ſmall bubbles of ice; from whence ſome have called it the Ice Plant, and others have named it the Diamond Plant, or Diamond Ficoides.

This ſort is propagated by ſeeds, which muſt be ſown on a hot-bed early in the ſpring; and when the plants come up, they muſt be planted on a freſh hot-bed to bring them forward; after they have taken root in the hot-bed, they ſhould have but little wet, for moiſture will rot them. When they are grown large enough to tranſplant again, they ſhould be each planted into a ſmall pot, filled with light freſh earth, but not rich, and plunged into a hot-bed of tan, obſerving to ſhade them in the heat of the day until they have taken new root; then they ſhould have plenty of freſh air admitted to them every day in warm weather, to prevent their drawing weak. In the latter end of June, ſome of the plants may be inured to bear the open air, and afterward they may be turned out of the pots, and planted into a warm border, where they will thrive, and ſpread their branches to a great diſtance upon the ground; but theſe plants will not be very productive of flowers, therefore ſome of them muſt be continued in the ſmall pots, and may at the ſame time, when the others are planted out, be removed into the ſtove or glaſs-caſe, placing them upon the ſhelves, that the roots may not get out from the bottom of the pots, ſo that they may be confined, which will cauſe them to flower plentifully, and from theſe good ſeeds may every year be obtained.

MESPILUS [Μέσπιλος, *Gr.*] Tourn. Inſt. R. H. 641. tab. 410. Lin. Gen. Plant. 549. *The Medlar.*

The Characters are,

The empalement of the flower is permanent, of one leaf, cut into five ſpreading concave ſegments. The flower is compoſed of five roundiſh concave petals, which are inſerted in the empalement. The number of ſtamina are different in the ſeveral ſpecies, from ten to twenty or more; theſe are alſo inſerted in the empalement, and are terminated by ſingle ſummits. The germen is ſituated under the flower, and ſupports an uncertain number of ſtyles from three to five, which are crowned by headed ſtigmas. The germen afterward becomes a roundiſh or oval berry, carrying the empalement on its top, and incloſing four or five hard ſeeds.

This genus of plants is ranged in the fourth ſection of Linnæus's twelfth claſs, which includes the plants whoſe flowers have twenty ſtamina inſerted to the empalement, and five ſtyles.

The Species are,

1. Mespilus (*Sylveſtris*) inermis, foliis lanceolatis dentatis acuminatis, ſubtus tomentoſis, calycibus acuminatis. *Smooth Medlar, with ſpear-ſhaped, acute-pointed, indented leaves, woolly on their under ſide, and acute-pointed empalements.* Meſpilus folio laurino major, fructu minori, rariori ſubſtantiâ. Hort. Cath. *Greater Medlar with a Bay-tree leaf, and a ſmaller leſs ſubſtantial fruit.*
2. Mespilus (*Germanica*) inermis foliis lanceolatis integerrimis ſubtus tomentoſis, calycibus acuminatis. Hort. Cliff. 189. *Unarmed Medlar with ſpear-ſhaped entire leaves, which are downy on their under ſide, and acute-pointed empalements.* Meſpilus Germanica, folio laurino, non ſerrato, ſive Meſpilus ſylveſtris. C. B. P. 453. *German Medlar with a Bay-tree leaf which is not ſawed, or wild Medlar.*
3. Mespilus (*Pyracantha*) ſpinoſa, foliis lanceolato-ovatis crenatis, calycibus fructûs obtuſis. Hort. Cliff. 189. *Prickly Medlar, with ſpear-ſhaped, oval, crenated leaves, and obtuſe empalements to the fruit.* Meſpilus aculeata, amygdali folio. Tourn. Inſt. 642. *Prickly Medlar with an Almond leaf, called Pyracantha.*
4. Mespilus (*Cordato*) foliis cordata-ovatis acuminatis, acutè ſerratis, ramis ſpinoſis. Fig. Plant. tab. 179. *Medlar with heart-ſhaped, oval, acute-pointed leaves, which are ſharply ſawed, and prickly branches.*
5. Mespilus (*Amelanchier*) inermis, foliis ovalibus ſerratis, cauliculis hirſutis. Lin. Sp. Plant. 478. *Medlar without thorns, having oval ſawed leaves, and hairy ſtalks.* Meſpilus folio rotundiori, fructu nigro ſubdulci. Tourn. Inſt. 642. *Medlar with a rounder leaf and a black ſweetiſh fruit, commonly called Amelanchier.*
6. Mespilus (*Canadenſis*) foliis ovato-oblongis glabris ſerratis, caule inermi. Lin. Sp. Plant. 478. *Medlar with oval, oblong, ſmooth, ſawed leaves, and branches without thorns.* Meſpilus inermis, foliis ſubtus glabris obverſè-ovatis. Flor. Virg. 54. *Medlar without thorns, and obverſe oval leaves, which are ſmooth on their under ſide.*
7. Mespilus (*Cotoneaſter*) foliis ovatis integerrimis. Hort. Cliff. 189. *Medlar with oval entire leaves.* Meſpilus folio ſubrotundo, fructu rubro. Tourn. Inſt. R. H. 642. *Medlar with a roundiſh leaf and a red fruit, commonly called Dwarf Quince.*
8. Mespilus (*Chamæmeſpilus*) inermis, foliis ovalibus ſerratis glabris, floribus capitatis, bracteis deciduis linearibus. Lin. Sp. Plant. 479. *Medlar without thorns, having ſmooth, oval, ſawed leaves, headed flowers, and linear bracteæ which fall off.* Cotoneaſter folio oblongo ſerrato. C. B. P. 452. *Baſtard Quince with an oblong ſawed leaf.*
9. Mespilus (*Orientalis*) foliis ovatis craſſis integerrimis, ſubtus tomentoſis, floribus umbellatis axillaribus. *Medlar with oval, thick, entire leaves, which are woolly on their under ſide, and flowers growing in umbels from the wings of the ſtalk.* Chamæceraſus Idæa. Alp. Exot. 5. *Dwarf Cherry of Mount Ida.*
10. Mespilus (*Arbutifolia*) inermis, foliis lanceolatis crenatis ſubtus tomentoſis. Hort. Cliff. 189. *Virginia Medlar with an Arbutus leaf.* Meſpilus Virginiana, folio arbuti. H. L. 578.
11. Mespilus (*Virginiana*) inermis, foliis oblongo-ovatis, ſubtus tomentoſis, fructu ovato, pedunculis longiſſimis. *Smooth Virginia Medlar, with oblong oval leaves, downy on their under ſide, and oval fruit on long foot-ſtalks.*

The firſt ſort grows naturally in Sicily, where it becomes a large tree; this riſes with a ſtraiter ſtem, and the branches grow more upright than thoſe of the Dutch Medlar; the leaves are narrower and not ſawed on their edges; the flowers are ſmaller than thoſe of the Dutch Medlar, and the fruit is ſhaped like a Pear.

The ſecond ſort is generally called the Dutch Medlar; this never riſes with an upright ſtalk, but ſends out crooked deformed branches at a ſmall height from the ground; the leaves of this are very large, entire, and downy on their under ſide. The flowers are very large, as are alſo the fruit, which are rounder, and approach nearer to the ſhape of an Apple. This being the largeſt fruit, is now generally cultivated in the gardens; but there is one with ſmaller fruit, which is called the Nottingham Medlar, of a much quicker and more poignant taſte than this; which is, I ſuppoſe, only a variety, ſo I have not enumerated it as a diſtinct ſpecies.

The fifth ſort grows naturally in Auſtria, Italy, and France, particularly near Fontainbleau; this riſes with many ſlender ſtalks about three or four feet high, which put out ſmall ſide branches, covered with a dark purple bark, having no thorns, cloſely garniſhed with oval leaves, about three quarters of an inch long, and half an inch broad, ſlightly ſawed on their edges; the ſmall ſide branches which ſuſtain the flowers, are very hairy and woolly, as are alſo the foot-ſtalks, and the under ſide of the leaves, but their upper ſides are ſmooth and green. The flowers come out in bunches at the end of the ſhoots, which have five long narrow petals, and about ten ſtamina in each. The flowers are ſucceeded by ſmall fruit, which, when ripe, are black; the gardeners call this New England Quince; there is one of this kind which grows naturally in North America, but the leaves of that are wedge-ſhaped and not ſawed on the edges, ſo I take it to be a different ſpecies.

The ſixth ſort grows naturally in Canada; this is alſo a low ſhrub, ſeldom riſing more than five feet high, dividing into ſeveral ſmooth branches, covered with a purpliſh bark. The leaves grow upon long ſlender foot-ſtalks; they are one inch and a half long, and an inch broad, ſmooth on both ſides, and a little ſawed on their edges. The flowers come out in ſmall bunches at the end of the branches; they are about the ſize of thoſe of the common Hawthorn, and are ſucceeded by ſmall fruit of a purpliſh colour when ripe.

The ſeventh ſort grows naturally on the Pyrenean mountains, and in other cold parts of Europe; this riſes with a ſmooth ſhrubby ſtalk about four feet high, dividing into a few ſmall branches, which are covered with a purple bark, and garniſhed with oval entire leaves, little more than one inch long, and about three quarters of an inch broad, having very ſhort foot-ſtalks. The flowers come out from the ſide of the ſtalks, two or three together; they are ſmall, of a purpliſh colour, and ſit cloſe to the ſtalks; theſe appear in May, and are ſucceeded by ſmall roundiſh fruit, which are of a bright red colour when ripe.

The eighth ſort grows naturally in the northern parts of Europe; this hath a ſmooth ſtalk, riſing about four or five feet high, ſending out ſlender branches, which are covered with a purpliſh bark, and garniſhed with oval ſmooth leaves about two inches long, and one inch and a half broad, ſawed on their edges, but the teeth point upward; they have pretty long ſlender foot-ſtalks, and are of a yellowiſh green on both ſides. The flowers come out from the wings of the ſtalk, four or five joined together in a cloſe head, of a purpliſh colour; between the flowers come out long narrow bractea, which are purpliſh, and fall off as the flowers begin to decay. The fruit is ſmall, and red when ripe.

The ninth ſort grows naturally upon mount Ida, in Crete, where the poor ſhepherds feed upon the fruit when ripe; this hath a ſmooth ſtalk about eight feet high, dividing into many ſmooth branches, garniſhed with oval leaves two inches and a half long, and near two inches broad, of a thick ſubſtance, and a dark green on their upper ſide, but downy on their under, ſtanding upon ſhort foot-ſtalks. The flowers come out from the ſide of the ſtalk upon ſhort ſmall branches, five or ſix growing upon each in a cloſe bunch; they are of a purple colour, the petals being but little longer than the empalement, which is woolly, and cut into five obtuſe ſegments. The fruit is large, roundiſh, and of a fine red colour when ripe.

The tenth ſort grows naturally in North America, where it rarely riſes more than five feet high, ſending out a few upright branches, garniſhed with ſpear-ſhaped leaves whoſe edges are crenated, and their under ſide downy; the flowers are produced in ſmall bunches on the ſide, and at the extremity of the branches, which are ſucceeded by ſmall roundiſh fruit a little compreſſed, of a purple colour when ripe.

The eleventh ſort is an inhabitant of the ſame country with the former; this riſes ſix or eight feet high, ſending out ſide branches, garniſhed with oblong, oval, entire leaves, downy on their under ſide; the flowers are produced in ſmall bunches, ſtanding on long foot-ſtalks, having each five narrow white petals which are contracted at their baſe, and are ſucceeded by oval fruit of a blue colour when ripe, and are by ſome of the inhabitants of America eaten in a ſcarcity of other ſorts of fruit, but are not very palatable.

All theſe ſorts are hardy enough to thrive in the open air in England, and ſome of them are very ornamental plants for gardens, where, during the ſeaſon of their flowering, they will make a fine appearance; and again, in autumn, when their fruit are ripe, they will afford an agreeable variety, and their fruit will be food for the deer and birds; ſo that if clumps of each ſort are planted in different parts of the garden, nothing can be more ornamental.

The American kinds are uſually propagated in the nurſeries, by grafting or budding them upon the common White Thorn, but the plants ſo propagated will never grow to half the ſize of thoſe which are propagated by ſeeds; ſo that thoſe plants ſhould always be choſen which have not been grafted or budded, but are upon their own roots.

But there are many who object to this method of raiſing the plants from ſeeds, on account of their ſeeds not growing the firſt year, as alſo from the tediouſneſs of the plant's growth after; but where a perſon can furniſh himſelf with the fruit in autumn, and take out their ſeeds ſoon after they are ripe, putting them into the ground immediately, the plants will come up the following ſpring, if they are kept clean from weeds, and in very dry weather ſupplied with water, they will make good progreſs; but if they are planted in the places where they are to remain, after two years growth from ſeeds, they will ſucceed much better than when the plants are of greater age; the ground ſhould be well trenched, and cleanſed from the roots of all bad weeds. The beſt time to tranſplant them is in autumn, when their leaves fall off; theſe ſhould be conſtantly kept clean from weeds, and if the ground between the plants is dug every winter, it will greatly encourage the growth of the plants, ſo that if they are cleaned three or four times in the ſummer, it will be ſufficient.

All the ſorts of Meſpilus and Cratægus will take, by budding or grafting upon each other; they will alſo take upon the Quince, or Pear ſtocks, and both theſe will take upon the Medlars; ſo that theſe have great affinity with each other, and might be with more propriety brought together under the ſame genus, than the Pear and Apple, which will not take upon each other; but although the Pear will take upon the White Thorn, yet it is not adviſeable to make uſe of theſe ſtocks, becauſe they generally cauſe the fruit to be ſmall and often to crack, and renders their fleſh ſtony; ſo unleſs it is the very ſoft melting kinds of Pears which are upon theſe ſtocks, the fruit will not be good.

MICROPUS. Lin. Gen. Plant. 892. Gnaphalodes. Tourn. Inſt. R. H. 439. tab. 261. Baſtard Cudweed.

The CHARACTERS are,

It hath hermaphrodite and female flowers, which are included in the ſame double empalement; there are ten hermaphrodite flowers which compoſe the diſk; theſe have one petal, are funnel-ſhaped, erect, and cut into five parts at the top, and have five ſhort briſtly ſtamina, terminated by cylindrical ſummits, with an obſolete germen ſupporting a ſhort ſlender ſtyle, crowned by an obſolete ſtigma. In the ſame empalement are five female flowers in the circumference, which have each an oval germen which is compreſſed, hid under the ſcales of the interior empalement, each having a ſtyle by their ſide, which is briſtly, turning toward the hermaphrodite flowers, crowned by ſlender acute-pointed ſtigmas, divided in two parts. The female flowers have each a ſingle oval ſeed ſucceeding them, included in the ſmall leaves of the empalement, but the hermaphrodite flowers are barren.

This genus of plants is ranged in the fourth ſection of Linnæus's nineteenth claſs, which includes thoſe plants whoſe flowers are compoſed of female fruitful flowers in the border, and barren hermaphrodite flowers in the middle.

We have but one Species of this genus in the Engliſh gardens, viz.

Micropus (*Supinus*) caule proſtrato, foliis geminis. Hort. Upſal. 275. Prod. Leyd. 145. *Micropus, or Baſtard Gnaphalium, with a trailing ſtalk.* Gnaphalodes Luſitanica. Tourn. Inſt. R. H. 439. *Portugal Baſtard Cudweed.*

This is an annual plant, which grows naturally in Portugal, near the ſea. The roots ſend out ſeveral trailing ſtalks about ſix or eight inches long, garniſhed with ſmall, oval, ſilvery leaves, whoſe baſe embrace the ſtalks. The flowers come out from the wings of the ſtalks in ſmall cluſters; they are very ſmall, white, and ſit in a double empalement, the interior being ſo large, as to almoſt hide the flowers. It flowers in June and July, and the ſeeds ripen in autumn; this is frequently preſerved in gardens for the beauty of its ſilvery leaves: if the ſeeds are ſown in autumn, or are permitted to ſcatter, the plants will come up in the ſpring, and will require no other care but to keep them clean from weeds, and thin them where they are too cloſe. When the ſeeds of this plant are ſown in the ſpring, they ſeldom grow the firſt year.

MICROSCOPE, a dioptrical inſtrument, by means of which very minute or ſmall objects are repreſented very large, and capable of being viewed very diſtinctly, according to the laws of refraction.

This inſtrument may be of ſingular uſe to a curious enquirer into the operation of vegetative nature, by viewing nicely the ſeveral minute veſſels and parts of vegetables, in order to diſcover their various uſes, and how the buſineſs of vegetation is carried on, as alſo to examine the minute parts of flowers, which are not obvious to the naked eye.

MILDEW is a diſeaſe that happens to plants, and is ſuppoſed to be cauſed by a dewy moiſture which falls on them, and continuing, for want of the ſun's heat to draw it up, and by its acrimony corrodes, gnaws, and ſpoils the inmoſt ſubſtance of the plant, and hinders the circulation of the nutritive ſap, upon which the leaves begin to fade, and the bloſſoms and fruit are much prejudiced: but Mildew is rather a concrete ſubſtance, which exſudes through the pores of the leaves.

However, what the gardeners commonly call Mildew, is an inſect, which is frequently found in great plenty, preying upon this exſudation.

Others ſay, That Mildew is a thick clammy vapour, exhaled in the ſpring and ſummer from plants, bloſſoms, and even the earth itſelf, in cloſe ſtill weather, where there is neither ſun enough to draw it upwards to any conſiderable height, nor wind of force ſtrong enough to diſperſe it, and that, hanging in the lower regions, when the cold of the evening comes on, it condenſes, and falls on plants, and with its thick clammy ſubſtance ſtops the pores, and by that means prevents perſpiration, and hinders the ſap from aſcending to nouriſh the flowers, ſhoots, &c.

Some ſay, That Mildew is a corroſive or nipping dew, proceeding from the vapours that are exhaled by the earth, which, being drawn up, and falling down again on the tender opening buds, infects them by its acrimony, and hinders the circulation of the nutritious ſap in the proper veſſels, upon which the leaves begin to fade, and the bloſſoms and fruit receive a very great prejudice.

There are others who make this obſervation, That the places moſt liable to Mildew are incloſed grounds and valleys, eſpecially thoſe that lie tending to the eaſt; and the reaſons that they give why thoſe grounds which lie from the horizon to the eaſt, are moſt ſubject to Mildew and blaſtings, may be by the ſun's attracting thoſe vapours towards it, after the manner that a great fire in a room draws the air to it; ſo the ſun having ſet theſe in motion, and not having ſtrength enough to draw them into the middle region, to form them into a cloud, he does yet draw them till he be below the horizon, and then theſe dews tend to the earth, from whence they were exhaled, and in motion to the weſt, do, as it were, fall upon the ground which lies eaſtward at right angles, and therefore is moſt offenſive to them.

But I take the true cauſe of the Mildew appearing moſt upon plants which are expoſed to the eaſt, to proceed from a dry temperature in the air when the wind blows from that point, which ſtops the pores of plants, and prevents their perſpiration, whereby the juices of the plants are concreted upon the ſurface of their leaves, which being of a ſweetiſh nature, inſects are incited thereto, where, finding proper nutriment, they depoſit their eggs, and multiply ſo faſt as to cover the whole ſurface of plants, and by their corroding the veſſels, prevent the motions of their ſap; and it is very probable, that the excrements of theſe inſects may enter the veſſels of plants, and by mixing with their juices, may ſpread the infection all over them; for it is obſervable, whenever a tree has been greatly affected by this Mildew, it ſeldom recovers it in two or three years, and many times is never entirely clear from it after.

Others ſuppoſe, That the reaſon why valleys afford more moiſture than hills is, becauſe of the dew which is attracted from the earth and herbs as before, and that they afford more moiſture than hills (they ſay) is often ſeen by the miſts, which are more frequent on them than on hills; this being drawn by the ſun in the day time, and wanting wind to aſſiſt its motion, hangs in the lower region, and when the ſun ſets, it falls upon the plants with its thick clammy ſubſtance, and hinders the ſap of the plant or tree from aſcending to nouriſh its flowers or ſhoots, in thoſe whoſe bark is tender and young, and the pores open with the heat of the ſeaſon.

This dew has been obſerved in the great leaved Cherries, ſuch as the Black Heart, the White Heart, &c. to fall upon them at the top, juſt at the beginning of the Midſummer ſhoot, which has ſo ſtopped the ſhoot that it has ſhot forth in other places below, and on the top of theſe ſhoots there have been many ſmall flies feeding on this dew, which may plainly be ſeen and taſted on the leaves of Oak and Maple.

Some are of opinion, that Mildews and blights are the ſame thing; but others again, that Mildew is quite another thing than blaſtings. They ſay Mildews are cauſed from the condenſation of a fat and moiſt exhalation in a hot and dry ſummer, from the bloſſoms and vegetables, and alſo from the earth itſelf, which is condenſed into a fat glutinous matter by the coolneſs and ſerenity of the air, and falls down on the earth again, part of which reſts upon the leaves of the Oak and other trees, whoſe leaves are ſmooth, and for that reaſon do not ſo eaſily admit the moiſture into them, as the Elm, and other rougher leaves do.

Other parts of Mildew reſt upon the ears and ſtalks of Wheat, beſpotting the ſame with a different colour from what is natural, being of a glutinous ſubſtance, by the heat of the ſun, and it binds up ſo cloſe the tender ears of Wheat, that it prevents the growth, and occaſions it to be very light in the harveſt.

Some are of opinion, that Mildews are the principal food of bees, it being ſweet, and eaſily converted into honey.

MILIUM. Tourn. Inſt. R. H. 514. tab. 298. Lin. Gen. Plant. 73. [ſo called of Mille, *Lat.* a thouſand, becauſe of the multitude of its grains.] Millet.

The Characters are,

It is of the Corn or Graſs tribe, with one flower in each chaff, the chaff opening with two oval acute-pointed valves. The petal of the flower is bivalve, and ſmaller than the empalement. It hath three very ſhort hairy ſtamina, terminated by oblong ſummits, and a roundiſh germen with two hairy ſtyles, crowned by bruſh-ſhaped ſtigmas. The germen afterward turns to a roundiſh ſeed, covered by the petal of the flower.

This genus of plants is ranged in the ſecond ſection of Linnæus's third claſs, which includes thoſe plants whoſe flowers have three ſtamina and two ſtyles.

The Species are,

1. Milium (*Panicum*) paniculâ laxâ flaccidâ, foliorum vaginis pubeſcentibus. *Millet with a looſe hanging panicle, and the ſheaths of the leaves hairy.* Milium ſemine luteo. C. B. P. 26. *Millet with a yellow ſeed.* Panicum Miliaceum. Lin. Sp.
2. Milium (*Sparſum*) paniculâ ſparsâ erectâ, glumis ariſtatis. *Millet with a looſe erect panicle, and bearded chaff.* Milium paniculâ amplâ erectâ ſparsâ. Houſt. MSS. *Millet with a large, erect, ſparſed panicle.*
3. Milium (*Effuſum*) floribus paniculatis diſperſis. Flor. Suec. 55. *Millet with diſperſed flowers.* Gramen ſylvaticum paniculâ miliaceâ ſparsâ. C. B. P. 3. *Wood Graſs with a ſparſed Millet-like panicle.*
4. Milium (*Confertum*) floribus paniculatis confertis. Prod. Leyd. 57. *Millet with panicles of flowers growing in cluſters.* Gramen paniculatum Alpinum, latifolium, paniculâ miliaceâ ſparsâ. Scheu. Gr. 34. *Broad-leaved, Alpine, Panicle Graſs, with a ſparſed Millet-like panicle.*

The firſt ſort grows naturally in India, but is now cultivated in many parts of Europe as an eſculent grain; this riſes with a Reed-like ſtalk from three to four feet high, and is channelled; at every joint there is one Reed-like leaf, which is joined on the top of the ſheath, which embraces and covers that joint of the ſtalk below the leaf; this ſheath is cloſely covered with ſoft hairs, but the leaf which is expanded has none; that has ſeveral ſmall longitudinal furrows running parallel to the midrib. The top of the ſtalk is terminated by a large looſe panicle, which hangs on one ſide, having a chaffy flower, which is ſucceeded by a ſmall round ſeed, which is often made into puddings, &c. There are two varieties of this, one with white, and the other hath black ſeeds, but do not differ in any other particular.

This plant is ranged under the title of Panicum, by Linnæus, but as it is more generally known by its former appellation, ſo I chuſe to continue it.

The ſecond ſort was diſcovered growing naturally at La Vera Cruz; this has a ſlenderer ſtalk than the former, which riſes about three feet high. The ſheaths which ſurround it have no hairs, but are channelled. The leaves are ſhorter than thoſe of the former. The panicle ſtands erect, and the chaff has ſhorter awns, or beards.

The other two ſorts grow naturally in woods, and are never cultivated in the fields, ſo do not require any farther deſcription.

The common Millet was originally brought from the Eaſtern countries, where it is ſtill greatly cultivated, from whence we are furniſhed annually with this grain, which is by many perſons greatly eſteemed for puddings, &c. but is ſeldom cultivated in England in quantity, but by way of curioſity in ſmall gardens, for feeding of poultry; but the ſeeds generally ripen very well.

They muſt be ſown the beginning of April, upon a warm dry ſoil, but not too thick, becauſe theſe plants divide into ſeveral branches, and ſhould have much room; and when they come up, they ſhould be cleared from weeds, after which they will, in a ſhort time, get the better of them, and prevent their future growth. In Auguſt theſe ſeeds will ripen, when it muſt be cut down, and beaten out, as is practiſed for other grain; but when it begins to ripen, if it be not protected from birds, they will ſoon devour it.

MILLEFOLIUM. See Achillea.

MILLERIA. Houſt. Gen. Nov. Martyn. Cent. 4. Lin. Gen. Plant. 881.

The Characters are,

This hath a compound flower, compoſed of ſeveral florets, and one half floret, which are included in one common empalement of one leaf, which is cut into three parts, and is permanent. The hermaphrodite florets have one tubulous petal, which is erect, and indented at the brim in five parts; theſe have five hairy ſtamina, with erect linear ſummits connected in their middle, to the ſide, and are the length of the petal, and an oblong narrow germen, ſupporting a ſlender ſtyle, crowned by two narrow, obtuſe, ſpreading ſtigmas; theſe florets are barren. The female half florets is of one leaf, ſtretched out on one ſide like a tongue, and is indented at the top; this hath a large three-cornered genmen, ſupporting a ſlender ſtyle, crowned by two long briſtly ſtigmas. The germen afterward turns to an oblong, three-cornered, obtuſe ſeed, incloſed in the empalement.

This genus of plants is ranged in the fourth ſection of Linnæus's nineteenth claſs, which includes thoſe plants with compound flowers, whoſe hermaphrodite flowers are barren, and the female flowers are fruitful.

The Species are,

1. Milleria (*Quinqueflora*) foliis cordatis, pedunculis dichotomis. Hort. Cliff. 426. *Milleria with heart-ſhaped leaves, and forked ſtalks.* Milleria annua, erecta, major, foliis conjugatis, floribus ſpicatis luteis. Houſt. MSS. *Greater, upright, annual Milleria, with leaves growing by pairs, and yellow ſpiked flowers.*
2. Milleria (*Maculata*) foliis infimis cordato-ovatis acutis rugoſis, caulinis lanceolato-ovatis, acuminatis. *Milleria whoſe lower leaves are oval, heart-ſhaped, acute-pointed, and rough, and the upper ones oval, ſpear-ſhaped, and pointed.* Milleria annua erecta ramoſior, foliis maculatis, profundiùs ſerratis. Martyn. Dec. 5. *Upright, annual, branching Milleria, with ſpotted leaves deeply ſawed.*
3. Milleria (*Biflora*) foliis ovatis, pedunculis ſimpliciſſimis. Hort. Cliff. 425. *Milleria with oval leaves, and ſingle foot-ſtalks.* Milleria annua erecta minor, foliis parietariæ, floribus ex foliorum alis. Houſt. MSS. *Smaller, upright, annual Milleria, with a Pellitory leaf, and flowers proceeding from the wings of the leaves.*
4. Milleria (*Triflora*) foliis ovato-lanceolatis acuminatis trinerviis, pedunculis alaribus trifloris. *Milleria with oval, ſpear-ſhaped, acute-pointed leaves, having three veins, and foot-ſtalks proceeding from the wings of the leaves, with three flowers.* Milleria annua erecta, foliis parietariæ longioribus, floribus ex foliorum alis. Edit. Prior. *Annual erect Milleria, with a longer Pellitory leaf, and flowers proceeding from the wings of the leaves.*

The firſt ſort was diſcovered by the late Dr. William Houſtoun, at Campeachy, in the year 1731, from whence he ſent the ſeeds to Europe; and as the characters which diſtinguiſh the genus, were different from all the other genera of the claſs to which it belongs, ſo he conſtituted a new genus with this title. This riſes with an herbaceous branching ſtalk from four to five or ſix feet high, garniſhed with heart-ſhaped leaves about four inches long, and three inches broad toward their baſe, drawing to a point at the end, which are ſlightly ſawed on their edges, having two veins on each ſide the midrib, which diverge and join to it near the baſe, meeting again at the point, which generally is oblique to the foot-ſtalk. The leaves are of a light green, and hairy, ſtanding oppoſite; their foot-ſtalks are about an inch long, and have a part of the leaf running on each ſide like wings. The ſtalks divide upward into forks, and the foot-ſtalks of the flowers come out at the diviſions; theſe branch again by pairs, and terminate in looſe ſpikes of yellow flowers, compoſed of four or five hermaphrodite florets, which are barren, and one female half floret, which is ſucceeded by a ſingle, oblong, angular ſeed, wrapped in the empalement of the flower. It flowers in July and Auguſt, and the ſeeds ripen in autumn.

The ſecond ſort was diſcovered by Mr. Robert Millar, at Campeachy, in the year 1734; this approaches near to the firſt ſort, but the ſtalks riſe ſix or ſeven feet high, branching out very wide. The leaves are ſeven inches long, and four inches and a half broad toward their baſe, ending in long acute points; they are deeper ſawed on their edges, and have ſeveral large black ſpots ſcattered over them; their ſurface is rougher, and they are of a darker green than thoſe of the firſt. The upper leaves are long and ſpear-ſhaped; the foot-ſtalks of the flowers branch out wider, and the ſpikes of flowers are ſhorter than thoſe of the firſt.

The third ſort was diſcovered at Campeachy by the late Dr. Houſtoun; this is alſo an annual plant, which riſes with an herbaceous ſtalk upward of two feet high, branching out at a ſmall diſtance from the root into three or four ſlender ſtalks, which are naked almoſt to the top, where they have two oval ſpear-ſhaped leaves placed oppoſite, which are about two inches long, and three quarters of an inch broad near their baſe, ending in points; they are hairy, and ſtand upon naked foot-ſtalks near an inch long, and are rough, having three longitudinal veins, and are ſlightly indented on their edges. The flowers come out at the foot-ſtalks of the leaves, in ſmall cluſters; the common empalement is compoſed of three orbicular leaves, which are compreſſed together; in each of theſe are ſituated two hermaphrodite florets, which are barren, and one female half floret, which is fruitful, being ſucceeded by a roundiſh angular ſeed, incloſed in the empalement. This flowers and perfects ſeeds about the ſame time with the former.

The fourth ſort was diſcovered by the late Mr. Robert Millar, at Campeachy; this is an annual plant, which riſes with an upright ſtalk three or four feet high, garniſhed the whole length with oval ſpear-ſhaped leaves near four inches long, and almoſt two broad near their baſe; they have three longitudinal veins, and toward the top there are two more which diverge from the midrib, but join again at the point. The upper ſide of the leaves are of a dark green and ſmooth, their under ſides are of a pale green, and indented on their edges. The flowers grow from the wings of the leaves in ſmall cluſters, having three hermaphrodite and one female flower in each, ſtanding upon ſhort foot-ſtalks; theſe have empalements like the former, but they are much ſmaller. This flowers and ſeeds later in the year than either of the former, ſo that unleſs the plants are brought forward in the ſpring, they will not ripen their ſeeds in England.

The ſeeds of theſe plants ſhould be ſown early in the ſpring, on a moderate hot-bed; and when the plants are come up about two inches high, they ſhould be each tranſplanted into a ſeparate pot filled with light rich earth, and plunged into a moderate hot-bed of tanners bark, being careful to ſhade them from the ſun until they have taken root, as alſo to water them frequently. After the plants are rooted, they ſhould have a large ſhare of free air admitted to them, by raiſing of the glaſſes of the hot-bed every day when the weather is warm, and in hot weather muſt be duly watered, for they are very thirſty plants. With this management, the plants will, in a month after tranſplanting, riſe to a conſiderable height; therefore they ſhould be ſhifted into larger pots, and placed in the ſtove, plunging them into the bark-bed, where they may have room to grow, eſpecially the firſt and ſecond ſorts, which uſually grow high and branch out where they are well managed. But the other ſorts ſeldom riſe above three or four feet high, and do not ſpread their branches very far, ſo theſe may be allowed leſs room.

In the middle of July theſe plants will begin to flower, and the ſeeds will be ripe about a month or ſix weeks after; therefore they muſt be gathered when they begin to change of a dark brown colour, otherwiſe they will ſoon fall off, eſpecially thoſe of the two large kinds, which will drop on the leaſt touch when they are ripe. Theſe plants will continue flowering till Michaelmas, or later, if the ſeaſon proves favourable; but when the cold of the autumn comes on, they will ſoon decay.

MIMOSA. Tourn. Inſt. R. H. 605. tab. 375. Lin. Gen. Plant. 597. The Senſitive Plant.

The Characters are,

The empalement of the flower is ſmall, of one leaf, indented in five parts at the top: the flower has one funnel-ſhaped petal, which hath five points. It hath many long hairy ſtamina, terminated by proſtrate ſummits, and an oblong germen ſupporting a ſhort ſlender ſtyle, crowned by a truncated ſtigma. The germen afterward turns to a long jointed pod with ſeveral tranſverſe partitions, incloſing compreſſed ſeeds of various forms, and there are many male, female, and hermaphrodite flowers mixed in ſome of the ſpecies.

This genus of plants Dr. Linnæus has joined to the Acacia of Tournefort, and the Inga of Plumier, and places it in the firſt ſection of his twenty-third claſs, which includes thoſe plants which have male, female, and hermaphrodite flowers on the ſame plant, which have many ſtamina and one ſtyle.

The Species are,

1. Mimosa (*Punctata*) inermis, foliis bipinnatis, ſpicis decandris, inferioribus caſtratis corollatis caule erecto tereti. Lin. Sp. 1502. *Senſitive Plant without ſpines, double winged leaves, ſpikes having ten ſtamina, and the lower without ſtamina, and an erect taper ſtalk.* Mimoſa Jamaicenſis. Zan. Hiſt. 144. *Senſitive Plant of Jamaica.*
2. Mimosa (*Plena*) inermis, foliis bipinnatis, ſpicis pentandris, inferioribus plenis. Hort. Upſal. 145. *Smooth Senſitive Plant with double winged leaves, the ſpikes with five ſtamina, and the under one double.* Mimoſa non ſpinoſa, paluſtris & herbacea, procumbens, flore luteo pleno. Houſt. MSS. *Herbaceous, marſh, trailing Senſitive Plant without ſpines, and a double yellow flower.*
3. Mimosa (*Pernambucana*) inermis decumbens, foliis bipinnatis, ſpicis cernuis, pentandris, inferioribus caſtratis. Hort. Upſal. 145. *Smooth Senſitive Plant with inclining ſtalks, double winged leaves, nodding ſpikes of flowers having five ſtamina, but the under ones without any.* Mimoſa ſpuria de Pernambuque, dicta mimoſa Italica. Zan. Hiſt. 151. *Spurions Senſitive Plant of Pernambuque, called Italian Senſitive Plant.*
4. Mimosa (*Pudica*) aculeata, foliis pinnatis. *Prickly Senſitive Plant with winged leaves.* Mimoſa herbacea procumbens, & ſpinoſa, caule tereti & villoſo, ſiliquis articulatis. Houſt. MSS. *Trailing herbaceous Senſitive Plant having ſpines, with a taper and hairy ſtalk, and jointed pods.*
5. Mimosa (*Pudica*) foliis ſubdigitatis pinnatis, caule aculeata, hiſpido. Lin. Sp. 1501. *Senſitive Plant with winged-handed leaves, a prickly declining ſtalk, and ſmall pods growing in cluſters, with prickly coverings.* Mimoſa humilis fruteſcens & ſpinoſa, ſiliquis conglobatis. Plum. Cat. *Low ſhrubby and prickly Senſitive Plant with cluſtered pods, commonly called the Humble Plant.*
6. Mimosa (*Quadrivalvis*) aculeata, foliis bipinnatis, caule quadrangulo, aculeis recurvis, leguminibus quadrivalvibus. Lin. Sp. Plant. 1508. *Prickly Senſitive Plant with double winged leaves, a four-cornered ſtalk, recurved ſpines, and pods having four valves.* Mimoſa herbacea procumbens, & ſpinoſa, caule quadrangulo, ſiliquis quadrivalvibus. Houſt. MSS. *Trailing and prickly herbaceous Senſitive Plant, with a quadrangular ſtalk, and pods having four valves.*
7. Mimosa (*Senſitiva*) foliis conjugatis pinnatis, partialibus bijugis, intimis minimis, caule aculeato. Lin. Sp. Plant. 1501. *Senſitive Plant with conjugated winged leaves, whoſe wings have two pair of lobes, the inner of which are the leaſt, and a prickly ſtalk.* Mimoſa ſpinoſa prima, ſive Braſiliana latifolia, ſiliquis, radiatis. Breyn. Cent. 1. 31. *The firſt prickly, or broad-leaved Senſitive Plant of the Brazils, with radiated pods.*
8. Mimosa (*Aſperata*) caule fruticoſo, foliis bipinnatis, aculeatis, aculeis geminis, ſiliquis radiatis hirſutis. Fig. Plant. tab. 183. fol. 3. *Senſitive Plant with a ſhrubby ſtalk, double winged prickly leaves, whoſe ſpines grow in pairs, and hairy radiated pods.* Æſchynomene ſpinoſa quarta, ſive foliolis Acaciæ anguſtioribus, frondibus validiſſimas ſpinas habentibus. Breyn. Cent. 1. 43. *The fourth prickly Senſitive Plant,*

Plant, with narrow Acacia leaves, armed with ſtrong ſpines.

9. Mimosa (*Viva*) inermis, foliis conjugatis pinnatis, partialibus quadrijugis ſubrotundis, caule inermi herbaceo. Lin. Sp. 1500. *Senſitive Plant with a creeping, herbaceous, unarmed ſtalk, conjugated winged leaves, and globular flowers proceeding from the wings of the ſtalks.* Mimoſa herbacea, non ſpinoſa, minima, repens. Sloan. Hiſt. Jam. 2. p. 58. *The leaſt creeping herbaceous Senſitive Plant, having no ſpines.*

10. Mimosa (*Nilotica*) ſpinis ſtipularibus patentibus, foliis bipinnatis, partialibus extimis glandula interſtinctis, ſpicis globoſis pedunculatis. Haſſelq. It. 475. *Acacia with double winged leaves, and globular ſpikes of flowers having foot-ſtalks.* Acacia Ægyptica. Hern. Mex. 866. *True Egyptian Acacia.*

11. Mimosa (*Farneſiana*) ſpinis ſtipularibus diſtinctis, foliis bipinnatis, partialibus octojugis, ſpicis globoſis ſeſſilibus. Hort. Upſal. 146. Acacia Indica foliis, ſcorpioidis leguminoſæ, ſiliquis fuſcis teretibus reſinoſis. H. L. *Indian Acacia with taper reſinous pods.*

12. Mimosa (*Cornigera*) ſpinis ſtipularibus geminis connatis, foliis bipinnatis. Hort. Cliff. 208. *Acacia with two ſpines joined at their baſe, and doubly winged leaves.* Acacia ſimilis Mexiocana, ſpinis cornu ſimilibus. *The great horned Acacia.*

13. Mimosa (*Unguis cati*) ſpinoſa, foliis bigeminis obtuſis. Hort. Cliff. 207. *Prickly Acacia with four obtuſe leaves.* Acacia quodammodo accedens, ſive Ceratia & Acacia media Jamaicenſis ſpinoſa, bigeminatis foliis, floſculis ſtamineis, atronitente fructu, ſiliquis intortis. Pluk. Phyt. *Acacia with branching leaves and twiſted pods.*

14. Mimosa (*Arborea*) inermis, foliis bipinnatis, pinnis dimidiatis acutis, caule arboreo. Lin. Sp. 1503. *Tree Acacia without thorns, doubly winged leaves, whoſe pinnæ are acute.* Acacia arborea maxima non ſpinoſo, pinnis majoribus flore albo, ſiliqua contorta coccinea verticoſa elegantiſſima. Sloan. Jam. 157.

15. Mimosa (*Purpurea*) inermis, foliis conjugatis pinnatis, foliis intimis minoribus. Lin. Sp. 1500. *Purple Acacia without ſpines, conjugated winged leaves which are ſmalleſt below.* Acacia Americana fruteſcens non aculeata, flore purpuraſcente. Plum. Cat. *Shrubby American Acacia with thorns, and a purpliſh flower.*

16. Mimosa (*Houſtoniana*) inermis, foliis bipinnatis glabris, pinnis tenuiſſimis, ſiliquis latis villoſis. Fig. Pl. 5. *Acacia without thorns, doubly winged ſmooth leaves, whoſe pinnæ are very narrow, and broad hairy pods.* Acacia Americana, non ſpinoſa, flore purpureo, ſtaminibus longiſſimis, ſiliquis planis villoſis, pinnis foliorum tenuiſſimis. Houſt. MSS. *American Acacia without thorns, having purple flowers, with very long filaments, flat hairy pods, and very narrow leaves.*

17. Mimosa (*Lutea*) aculeata, foliis bipinnatis glabris, floribus globoſis pedunculatis, aculeis longiſſimis. *Prickly Acacia with ſmooth doubly winged leaves, globular flowers having foot-ſtalks, and very long ſpines.* Acacia ſpinoſa, foliorum pinnis tenuiſſimis glabris, floribus globoſis lutea, ſpinis longiſſimis. Houſt. MSS. *Prickly Acacia with very narrow ſmooth leaves, round yellow flowers, and very long thorns.*

18. Mimosa (*Glauca*) inermis, foliis bipinnatis, partialibus ſejugis, pinnis plurimis, glandula inter infima. Lin. Sp. Plant. 1502. *Acacia without thorns, doubly winged leaves, whoſe wings are ſeparated, and have ſmall glands between them.* Acacia non ſpinoſa, flore albo, foliorum pinnis latiuſculis glabris, ſiliquis longis planis. Houſt. MSS. *White flowering Acacia without thorns, having broad ſmooth leaves, and long flat pods.*

19. Mimosa (*Anguſtiſſima*) inermis, foliis bipinnatis, pinnis anguſtiſſimis glabris, leguminibus tumidis. *Narrow-leaved unarmed Acacia, with doubly winged ſmooth leaves, and jointed pods.* Acacia non ſpinoſa, floribus globoſis albis foliorum pinnis tenuiſſimis glabris, ſiliquis ad ſingula grana tumidis. Houſt. MSS. *Acacia without thorns, having round white flowers, with very narrow ſmooth leaves, and jointed pods.*

20. Mimosa (*Campeachiana*) ſpinoſa, foliis bipinnatis, pinnis anguſtis, ſpinis ſingulis cornu bovinum per longitudinem fiſſum referentibus. *Acacia with doubly winged leaves having narrow pinnæ, and ſingle ſpines like ox's horns ſplit their length.* Acacia ſpinoſa tenuifolia, ſpinis ſingulis cornu bovinum per longitudinem fiſſum referentibus. Houſt. Cat. *Acacia with ſingle thorns ſhaped like thoſe of an ox's horn, and ſeem as if ſplit thro' their length.*

21. Mimosa (*Cinerea*) ſpinis ſolitariis, foliis bipinnatis, floribus ſpicatis. Flor. Zeyl. 215. *Acacia with ſingle ſpines, doubly winged leaves, and ſpiked flowers.* Acacia ſpinoſa tenuifolia, ſiliquis latis, ſpinis minimis recurvis ſolitariis. Houſt. Cat. *Prickly narrow-leaved Acacia with broad pods, and ſmall recurved ſpines, which come out ſingle.*

22. Mimosa (*Latifolia*) inermis, foliis conjugatis, pinnis terminalibus oppoſitis, lateralibus alternis. Lin. Sp. 1499. *Broad-leaved Acacia without thorns, conjugated leaves whoſe upper pinnæ are oppoſite, but the ſide ones are alternate.* Acacia non ſpinoſa, juglandis folio, flore purpuraſcente. Plum. Sp. 17. *Acacia without thorns, Walnut-tree leaves, and a purple flower.*

23. Mimosa (*Circinalis*) aculeata, foliis conjugatis pinnatis, pinnis æqualibus, ſtipulis ſpinoſis. Lin. Sp. 1499. *Prickly Acacia with conjugated winged leaves, which are equal, and prickly ſtipulæ.* Acacia foliis amplioribus, ſiliquis circinatis. Plum. Sp. 17. *Acacia with broad leaves and twiſted pods.*

24. Mimosa (*Fagifolia*) inermis, foliis pinnatis bijugis petiolo marginato. Lin. Sp. 1498. *Broad-leaved Acacia without ſpines, whoſe wings have four lobes, and running foot-ſtalks.* Arbor ſiliquoſa, faginis foliis, Americana, floribus comoſis. Pluk. Phyt. tab. 141. fol. 2.

The firſt ſort grows naturally in moſt of the iſlands in the Weſt-Indies, and it has been found growing in ſome warm moiſt ſpots, as far north as Virginia. This riſes with upright branching ſtalks ſix or ſeven feet high, which become ligneous toward the root, but are not perennial (at leaſt they are not ſo here in any ſituation, the plants always decaying in winter;) theſe are ſmooth, and garniſhed with double winged leaves, compoſed of four or five pair of long winged lobes, which have about twenty pair of ſmall leaves ranged along the midrib; they are ſmooth and rounded at their points, of a full green on their upper ſide, but pale on their under. Theſe ſmall leaves contract themſelves together on their being touched, but the foot-ſtalks do not decline at the ſame time, as thoſe do which are titled Humble Plants, ſo this is called the Senſitive Plant by way of diſtinction. The flowers are produced upon long foot-ſtalks, which come out from the wings of the leaves, and are diſpoſed in globular heads which nod downward; they are yellow, and all thoſe which have petals have ten ſtamina in each, but thoſe ſituated round the border have neither petals or ſtamina; thoſe on the upper part of the ſpike are ſucceeded by pods an inch and a half long, and a quarter of an inch broad, which change to a dark brown when ripe, incloſing three or four compreſſed, ſhining, black ſeeds.

The ſecond ſort was diſcovered by the late Dr. Houſtoun at La Vera Cruz, growing in ſtagnant waters, where the ſtalks were very broad and flat, and floated on the ſurface, in the ſame way as the pond weeds do; but in thoſe places where the water was dried up the ſtalks grew upright and were round, which is always the caſe when the plants are cultivated in gardens, ſo that they might eaſily paſs for different plants, to thoſe who never ſaw them growing in both ſituations. When this ſort is cultivated in gardens, it has great reſemblance to the firſt, but the ſtalks of this never grow ſo erect, the wings of the leaves are longer, and ſtand more horizontal; the heads of flowers are much larger, the ſtamina are longer, and the flowers on the under ſide of the ſpike which have no ſtamina are double: the pods of this ſort are ſhorter, and much broader than thoſe of the firſt ſort. This is alſo an annual plant in this country. This ſort was ſince diſcovered by a friend of mine, growing naturally in a marſhy ſpot of land in the iſland of Barbuda, from whence he ſent me the ſeeds, with a large branch of the plant, in a glaſs filled with a lixivium, which preſerved it in the ſtate it was gathered, with the flowers and pods upon it.

The third ſort grows naturally in all the iſlands of the Weſt-Indies, where it is titled the ſlothful Senſitive Plant, becauſe the leaves do not contract on their being touched. The ſtalks of this ſort ſeldom riſe more than two feet and a half high, they are ſmooth, and garniſhed with double-winged leaves, compoſed of three or four pair of wings which are ſhorter, and the ſmall leaves are much narrower than thoſe of the two former ſorts; the heads of flowers are ſmaller, and the pods are longer and narrower than thoſe of the other. This ſort will live through the winter in a moderate warm air.

The fourth ſort was diſcovered by the late Dr. Houſtoun, growing naturally at La Vera Cruz. This hath ligneous ſtalks which decline to the ground, ſpreading out two or three feet from the root, and ſend out ſeveral ſide branches, which are armed with ſhort yellowiſh ſpines under the foot-ſtalks of the leaves, and are their whole length cloſely covered with briſtly ſtinging hairs; the foot-ſtalks of the leaves are three inches long, and at the top ſuſtain four ſingle winged leaves, whoſe baſe meet in a point, but ſpread above like the fingers of an open hand. Theſe wings are about three inches long, and are cloſely garniſhed with ſmall narrow lobes, ſet by pairs along the midrib, which is alſo covered on the under ſide with the like briſtly hairs as the ſtalk. The flowers come out from the wings of the leaves upon pretty long foot-ſtalks; they are collected into globular heads, and are of a pale yellowiſh colour; theſe are ſucceeded by ſmall jointed pods, containing two or three ſhining black ſeeds.

The fifth ſort is the moſt common of any in the iſlands of the Weſt-Indies, as alſo in the Engliſh gardens; the ſeeds of this ſort are frequently ſold in the ſeed-ſhops, by the title of Humble Plant. The roots of this are compoſed of a great number of hairy fibres, which mat cloſe together, from which come out ſeveral ligneous ſtalks which naturally decline toward the ground, unleſs they are ſupported; they are armed with ſhort recurved ſpines, and garniſhed with winged leaves, compoſed of four, and ſometimes five wings, whoſe baſe join at a point, where they are inſerted to the foot-ſtalk, ſpreading upward like the fingers of a hand; theſe wings are ſhorter than thoſe of the former ſort, and the ſtalks are not hairy. The flowers come out from the wings of the ſtalks, upon ſhort foot-ſtalks; they are collected in ſmall globular heads, are yellow, and are ſucceeded by ſhort, flat, jointed pods, which have two or three orbicular, bordered, compreſſed ſeeds in each: theſe pods are in cloſe cluſters, almoſt covered with ſtinging hairy covers.

The ſixth ſort grows naturally at La Vera Cruz, from whence the late Dr. Houſtoun ſent the ſeeds. This hath a perennial creeping root, which ſpreads and multiplies greatly in the ſands, where it grows wild; the ſtalks are ſlender, and have four acute angles, armed with ſhort recurved ſpines pretty cloſely; the leaves ſtand upon long prickly foot-ſtalks, which are thinly placed on the branches; they are compoſed of two pair of wings, ſtanding about an inch aſunder; the wings are ſhort, and the ſmall leaves are narrow, and not placed ſo cloſe together, as in many of the other ſpecies. The foot-ſtalks of the flowers come out from the wings of the leaves, ſuſtaining a ſmall globular head of purple flowers; theſe are ſucceeded by four-cornered pods about two inches long, which have four cells, opening with four valves, containing ſeveral angular ſeeds in each.

This ſort ſpreads ſo much at the root, as to render it not ſo productive of flowers and ſeeds as moſt of the others; and the plants which are propagated by parting of the roots, are always weak, ſo that the beſt way is to propagate them by ſeeds, when they can be obtained. This is one of the ſorts, whoſe foot-ſtalks fall on being touched.

The ſeventh ſort grows naturally at La Vera Cruz, from whence the late Dr. Houſtoun ſent the ſeeds. This riſes with a ſlender ligneous ſtalk ſeven or eight feet high, armed with ſhort recurved thorns. The leaves grow upon long foot-ſtalks which are prickly, each ſuſtaining two pair of wings; the exterior pair have two lobes which join at their baſe, and are rounded on their outſide, but ſtrait on their inner edges, very much ſhaped like a pair of thoſe ſhears uſed for ſhearing of ſheep; theſe two outer pair of lobes are much larger than the inner; they are almoſt two inches long, and one broad in the middle. From the place where theſe are inſerted to the ſtalk, come out ſmall branches which have three or four globular heads of pale purple flowers coming out from the ſide, upon ſhort foot-ſtalks, and the principal ſtalk has many of thoſe heads of flowers on the upper part for more than a foot in length; and this, as alſo the branches, are terminated by the like heads of flowers: theſe are ſucceeded by broad, flat, jointed pods, which open with two valves, ſome having but one, others two, and ſome have three orbicular compreſſed ſeeds. The leaves of this ſort move but ſlowly when they are touched, but the foot-ſtalks fall when they are preſſed pretty hard.

The eighth ſort was alſo found by the ſame gentleman, growing naturally at La Vera Cruz. This hath a ſhrubby erect ſtalk about five feet high, which is hairy, and armed with ſhort, broad, ſtrong thorns, which are white, ſtanding on each ſide ſometimes almoſt oppoſite, and at others alternately. The leaves are compoſed of five or ſix pair of wings, which are ranged oppoſite along a ſtrong midrib, and between each pair are placed two ſhort ſtrong ſpines, pointing out each way. The ſmall leaves which compoſe theſe wings are extremely narrow, and ſtand very cloſe to each other. Toward the upper part of the ſtalk, the flowers are produced from the ſides, upon ſhort foot-ſtalks; they are collected into globular heads, and are of a bright purple colour; the ſtalks are alſo terminated by ſmaller heads of the like flowers. Theſe are ſucceeded by flat jointed pods about two inches long, and a quarter of an inch broad, which ſpread open like rays, there being commonly five or ſix of theſe joined together at their baſe to the foot-ſtalk. Theſe pods ſeparate at each articulation, leaving the two ſide membranes or borders ſtanding; and the ſeeds which are compreſſed and ſquare, drop out from the joints of the pods; theſe pods are hairy at firſt, but as they ripen become ſmooth.

This is a perennial plant, which may be preſerved through the winter in a warm ſtove, by which method the ſeeds may be obtained, for they ſeldom flower the firſt year. The foot-ſtalks of this ſort do not fall on being touched, but the ſmall leaves on the wings cloſe up.

The ninth ſort grows naturally in Jamaica; this hath trailing herbaceous ſtalks, which put out roots at every joint, which faſten in the ground and ſpread to a great diſtance, as they will alſo do here, when placed in a bed of tanners bark. I have had a ſingle plant in one ſummer, which has ſpread near three feet ſquare, whoſe branches were cloſely joined, ſo as to cover the ſurface of the bed; but when they are thus permitted to grow, they ſeldom produce flowers. Theſe ſtalks have no thorns, but are garniſhed with winged leaves compoſed of two pair of ſhort wings, whoſe ſmall leaves or lobes are narrow; theſe ſtand upon ſhort foot-ſtalks, which are ſmooth. The leaves of this ſort contract and fall down upon the leaſt touch, ſo that where the plant is extended to a diſtance, a perſon may draw any figure with a ſtick upon the leaves, which will be very viſible till the leaves recover again. The flowers come out from the wings of the leaves, upon naked foot-ſtalks about an inch in length; they are of a pale yellowiſh colour, and are collected into ſmall globular heads; theſe are ſucceeded by ſhort, flat, jointed pods, containing three or four compreſſed roundiſh ſeeds.

Theſe plants are all of them propagated by ſeeds, which ſhould be ſown early in the ſpring, upon a good hot-bed. If the ſeeds are good, the plants will appear in a fortnight or three weeks, when they will require to be treated with care, for they muſt not have much wet till they have acquired ſtrength; nor ſhould they be drawn too weak, ſo that freſh air ſhould be admitted to them at all times when the air is temperate. In about a fortnight or three weeks after the plants come up, they will be fit to tranſplant, eſpecially if the bed in which they were ſown, continues in a proper degree of heat; then there ſhould be a freſh hot-bed prepared to receive them, which ſhould be made a week before the plants are removed into it, that the violent heat may be abated before the earth is laid upon the dung, and the earth ſhould have time to warm before the plants are planted into it. Then the plants muſt be carefully raiſed up from the bed to preſerve the roots entire, and immediately planted in the new bed, at about three or four inches diſtance, preſſing the earth gently to their roots; then they ſhould be gently ſprinkled over with water, to ſettle the earth to their roots; after this they muſt be ſhaded from the ſun till they have taken new root, and the glaſſes of the hot-bed ſhould be covered every night to keep up the heat of the bed. When the plants are eſtabliſhed in their new bed, they muſt have frequent, but gentle waterings; and every day they muſt have free air admitted to them, in proportion to the warmth of the ſeaſon, to prevent their being drawn up weak; but they muſt be conſtantly kept in a moderate degree of heat, otherwiſe they will not thrive. In about a month after the plant will be ſtrong enough to remove again, when they ſhould be carefully taken up, preſerving as much earth to their roots as poſſible, and each planted in a ſeparate ſmall pot, filled with good kitchen-garden earth, and plunged into a hot-bed of tan, carefully ſhading them from the ſun till they have taken new root; then they muſt be treated in the ſame manner as other tender exotic plants from very warm countries.

The ſorts which grow upright and tall, will ſoon riſe high enough to reach the glaſſes of the hot-bed, eſpecially if they thrive well; therefore they ſhould be ſhifted into larger pots, and removed into the ſtove, and if they are plunged into the tan-bed there, it will greatly forward them. The firſt ſort will often flower here, if the plants are raiſed early in the ſpring, and brought forward by their removal from one hot-bed to another; and two or three times I have had their ſeeds ripen, but this can only be expected in very warm ſeaſons.

The perennial ſorts will live through the winter, if they are preſerved in a warm ſtove, and the following ſummer they will produce flowers and ripen their ſeeds. Some of theſe may be propagated by laying down their branches, which will put out roots, and then may be ſeparated from the old plants; and I have ſometimes propagated them by cuttings, but the plants which riſe from ſeeds are preferable to either of theſe.

There is no particular management which theſe plants require, different from others of the ſame warm countries; the great care muſt be to keep them in a proper temperature of heat, and not to give them too much water, eſpecially in cool weather; nor ſhould they be kept too dry, for many of the ſorts require frequent waterings, as they naturally grow in moiſt places. There ſhould alſo be care taken that they do not root into the tan-bed, for they ſoon put out their roots through the holes at the bottom of the pots, which, when they ſtrike into the tan, will cauſe the plants to grow very luxuriant; but when they are removed, and theſe roots are cut or broken off, the plants ſeldom ſurvive it; therefore the pots ſhould be frequently drawn out of the tan, and if any of the roots are beginning to get through the holes at the bottom, they ſhould be cut off cloſe; and when the roots are very cloſely matted together, they ſhould be turned out of the pots, and pared round to reduce them, and then potted again, either in pots of the ſame ſize, or if the plants require, in pots one ſize larger; but they muſt not be over-potted, for then the plants will not thrive.

Some of thoſe ſorts whoſe ſtalks ſpread near the ground, may be turned out of the pots in the middle of June, and planted in a very warm border, where, if they are covered with bell or hand-glaſſes, they will live through the ſummer; but theſe will not grow very large, and upon the approach of cold in the autumn, they are ſoon deſtroyed: however, thoſe who have not conveniency of ſtoves or tan-beds, may raiſe the plants on common hot-beds in the ſpring; and when they have acquired ſtrength, they may be treated in this manner, whereby they will have the pleaſure of theſe plants in ſummer, though not in ſo great perfection, as thoſe who have the advantages beforementioned: but theſe plants will not thrive in the open air in this country, nor will they retain their ſenſibility when they are fully expoſed to the air.

It would be to little purpoſe to trouble the reader with the ſeveral idle ſtories related of theſe plants by travellers, nor to inſert what has been ſaid by others, who have attempted to account for the motion of the leaves of theſe plants on their being touched, ſince there has not been any thing wrote on this ſubject, worthy of being noticed, that I have yet ſeen; I ſhall therefore only mention what I have myſelf obſerved in theſe plants, for more than forty years that I have cultivated them.

The firſt is, that they are more or leſs ſuſceptible of the touch or preſſure, according to the warmth of the air in which they grow; for thoſe plants which are kept in a warm ſtove, contract their leaves immediately on being touched, either with the hand, a ſtick, or any other thing, or by the wind blowing upon them: ſome of the ſorts only contract their ſmall leaves, which are placed along the midrib; others not only contract their ſmall leaves, but the footſtalk alſo declines downward on being touched: the firſt are called Senſitive, and the ſecond Humble Plants; but when theſe plants are placed in a cooler ſituation, they do not move ſo ſoon, nor contract ſo cloſely, as thoſe which are in a greater warmth; and thoſe which are entirely expoſed to the open air, have very little motion, but remain in one ſtate, neither expanded nor cloſed, but between both, eſpecially in cool weather; nor do theſe ſhut themſelves at night, as thoſe do which are in a warm temperature of air.

The ſecond is, that it is not the light which cauſes them to expand, as ſome have affirmed, who have had no experience of theſe things; for in the longeſt days of ſummer, they are generally contracted by five or ſix in the evening, when the ſun remains above the horizon two or three hours longer; and although the glaſſes of the ſtove in which they are placed, is covered cloſe with ſhutters to exclude the light in the middle of the day, yet if the air of the ſtove is warm, the leaves of the plants will continue fully expanded, as I have ſeveral times obſerved. Nor do theſe plants continue ſhut till the ſun riſes in the morning, for I have frequently found their leaves fully expanded by the break of day in the morning; ſo that it is plain the light is not the cauſe of their expanſion, nor the want of it that of their contraction.

I have alſo obſerved, that thoſe plants which are placed in the greateſt warmth in winter, continue vigorous, and retain their faculty of contracting on being touched; but thoſe which are in a moderate warmth, have little or no motion.

When any of the upper leaves of theſe plants are touched, if they fall down and touch thoſe which are below them, it will occaſion their contracting and falling, ſo that by one touching another, they will continue falling for ſome time. When the air of the ſtove in which theſe plants ſtand, is in a proper temperature of warmth, the plants will recover themſelves, and their leaves will be fully expanded in about eight or ten minutes. I have frequently watched them as they have been recovering, and have always found it has been by a vibratory motion, like the index of a clock.

Some of the ſorts are ſo ſuſceptible of the touch, that the ſmalleſt drop of water falling on their leaves will cauſe them to contract, but others do not move without a much greater preſſure.

The roots of all the ſorts have a very ſtrong diſagreeable odour, almoſt like that of a common ſewer. I have met with ſome accounts of theſe plants, in which it is mentioned, that the leaves and branches have a poiſonous quality, and that the Indians extract a poiſon from them, which kills by ſlow degrees, and that the root of the plant is the only remedy to expel it; but how far this is true I cannot ſay, having never made any experiments on the qualities of theſe plants; but if theſe plants are endowed with ſo deadly a quality as related, this ſenſibility with which they are endued, may be deſigned by providence to caution perſons from being too free with it; and as many of them are ſtrongly armed with thorns, ſo that is a guard againſt their being eaten by animals; for in all the enquiries which I have made of thoſe perſons who have reſided in the countries where they naturally grow, I could never learn that any animal will browſe upon them.

Theſe plants are all of them natives of America, ſo were unknown to the other parts of the world till that was diſcovered, for I have not heard of any of them being found in any other country: and a few years ago I ſent ſome of the ſeeds of theſe plants to China, which ſucceeded, and occaſioned great admiration in all who ſaw the plants.

The Acacias are ſo nearly allied to the Mimoſas in their characters, that Linnæus has joined them in the ſame genus; and as his ſyſtem is now generally followed, ſo in compliance with that I have done the ſame.

The tenth ſort of Acacia is the tree from whence the true Succus Acaciæ is taken, and the Gum Arabic exſudes from the branches of the ſame; which, though mentioned as a native of Egypt, yet it is alſo found in divers parts of America, from whence the ſeed of this tree have been ſent into England, and there raiſed in ſeveral gardens near London.

This tree arrives to a large ſize in the countries where it grows, but in England is rarely ſeen more than eight or ten feet high. It frequently flowers in autumn, but never produces any ſeeds.

The eleventh ſort is the moſt common kind in Jamaica and Barbadoes, and the other warm parts of America; and, for the ſweetneſs of its flowers, has been diſperſed through moſt parts of Europe; and though a native of the warmer parts of the Indies, it hath been made familiar to the Italian gardens, and is cultivated likewiſe in great plenty in Portugal and Spain.

The Italian gardeners, who bring over Orange-trees, &c. every year, generally bring alſo many young plants of this ſort to England, under the title of Gazia; but as they are too tender to live in a common green-houſe in England, ſo few of thoſe which are purchaſed of them ſucceed.

I have had ſome plants of this ſort upwards of ſixteen feet high, which have produced great numbers of flowers in July and Auguſt, but theſe were kept in a ſtove in winter, and in glaſs-caſes in ſummer, to ſcreen them from wet and the cold, for they will not flower in the open air in this country. The flowers are of a bright yellow colour, and ſmell ſweet; in the Weſt-Indies it is called Sponge-tree.

The twelfth ſort is at preſent very rare in England, and only to be found in ſome curious gardens. This tree produces its ſpines by pairs, which are extreme large and crooked, and of a whitiſh colour; but I do not remember ever to have ſeen this flower.

In England, from the dried ſamples however, which I have received from Campeachy, with many flowers upon them, there appears but little beauty in them; nor do the trees in their native ſoil make a better appearance, their branches always growing deformed, and being but thinly garniſhed with leaves, when in their greateſt vigour; but for ſeveral months they are deſtitute of leaves, ſo that the only thing remarkable in this tree is, the uncommon wreathed ſpines with which the trunk and branches are fully beſet. Theſe have the reſemblance of animal horns, and are variouſly twiſted and contorted.

The twenty-third ſort was brought from the Bahama Iſlands by Mr. Cateſby, anno 1726. The ſeeds of this plant (which are flat, and one half of a beautiful red colour, the other half of a deep black) grow in long twiſted pods, opening when the ſeeds are ripe, on one ſide, and letting them out, which hanging by a ſmall thread for ſome time out of the pods, make a very agreeable appearance; the leaves of this tree branch out and divide into many ramifications: the lobes are roundiſh, and placed in a very regular order. The flowers have not as yet appeared in England, but from a painting done from the plant in the country, they ſeem to be very beautiful.

The thirteenth ſort was brought from Jamaica, and is growing in the phyſic-garden at Chelſea; this hath four large lobes to each leaf; the ſpines are ſhort, ſtiff, and crooked, and the ſeeds grow in twiſted pods like the former. This plant is well deſcribed in Sir Hans Sloane's Natural Hiſtory of Jamaica. By the inhabitants of America it is called Doctor Long, under which name the ſeeds are frequently brought to England.

Moſt of the other ſorts here mentioned, were collected by the late ingenious Dr. William Houſtoun, in Jamaica, at Vera Cruz and Campeachy, who ſent the ſeeds of moſt of them into Europe, many of which are now growing in the phyſic-garden at Chelſea, where ſome of them have produced flowers and plenty of ſeeds.

Theſe being all tender, are to be placed in ſtoves in the winter, and in ſummer muſt be but a ſhort time expoſed to the open air, and have a warm ſituation.

They are propagated by ſowing their ſeeds on a hot-bed in the ſpring of the year, which will in a ſhort time appear above ground, and in about five or ſix weeks after, be fit to tranſplant, when a freſh hot-bed is to be prepared for them, and ſhould be pretty warm; the next thing to be provided is a quantity of ſmall halfpenny pots, which are to be filled with freſh, light, ſandy earth; theſe ſhould be plunged into the hot-bed, but not into dung; for if theſe beds are made with warm horſe dung, they ought to be covered with earth as deep as the pots, whoſe bottoms ſhould reſt upon the dung, for otherwiſe the roots of the plants may ſuffer by too much heat; but beds of tanners bark ſeldom heat ſo violently. As ſoon as the earth in the pots is warm, which will be in two or three days, you ſhould carefully take up the young plants out of the firſt hot-bed, planting four or five plants into each of theſe pots, giving them a gentle watering to ſettle the earth to their roots, and ſcreening them with mats over the glaſſes from the heat of the ſun, until they have taken root; after which time you muſt give them air, by raiſing the glaſſes in proportion to the heat of the weather, or to the conſtitution of the plants.

The tenth, eleventh, and twelfth, ſorts are very tender, eſpecially while young, therefore ſhould have a hot-bed of tanners bark; and as they increaſe in bulk, ſhould be ſhifted into bigger pots. The earth for theſe ſhould be a little lighter, and more inclined to a ſand, than for the other ſorts; but never plant them in pots that are too large, which is full as bad to theſe as to Orange-trees; neither give them too much water, eſpecially in winter. The tenth ſort being the hardieſt of the three, will, when grown to be woody, ſtand in a common ſtove, which ſhould be kept to the point of temperate heat in winter; and in the ſummer time, in warm weather, may enjoy the open free air: but the eleventh and twelfth ſorts muſt have a bark-ſtove in winter; nor ſhould they be expoſed to the open air in ſummer, at leaſt for four or five years, until they are grown very woody, for they are very tender, and with great difficulty preſerved in this climate. The ſtove in which theſe ſhould be placed in winter, muſt be kept above the temperate point, as marked in the botanical thermometers. Theſe ſhould have very little water in winter, but in ſummer time will require frequent refreſhings, though at that ſeaſon it ſhould not be given them in great quantities at one time. The eleventh ſort is a very beautiful tree. The twelfth ſheds its leaves juſt before the new ones come on, ſo that it is naked of leaves about a month or ſix weeks in the ſpring of the year, which has occaſioned ſome people to throw them away as dead, when, if they had let them remain, they would have come out freſh again. This I thought proper to mention, in order to caution people not to be too haſty in throwing out trees for dead, but preſerve them through the ſucceeding ſummer, to ſee if they will ſhoot again; for I have known ſeveral plants, which, after having been given over by unſkilful perſons for dead, have the July following ſhot out vigorouſly again; and others, which have died to the ſurface of the earth, have riſen again from the root.

The three ſorts of horned Acacias are very often deſtitute of leaves for two or three months, appearing to have no life; but they will put out freſh leaves towards autumn, which is commonly the ſeaſon when they are moſt vigorous. Theſe ſhould be expoſed in the ſummer ſeaſon for about two months, to clear them from inſects, which greatly infeſt them, in a place defended from ſtrong winds; and in the winter they require a moderate degree of warmth.

All the other ſorts here mentioned are propagated by ſeeds, which, ſeldom ripening in this country, muſt be procured from America, particularly at Campeachy, where there is great variety of this tree, many ſorts of which have been hitherto unknown to botanical writers. In bringing over the ſeeds of theſe trees, they ſhould be taken out of the pods when gathered, and put up in papers, and ought to have Tobacco, or ſome other noxious herb, put between the papers, to keep off inſects, otherwiſe the ſeeds will be eaten and deſtroyed before they arrive in England. For the inſects depoſit their eggs in ſmall punctures which they make in the pods; and as theſe are ſoon hatched, ſo they immediately attack the ſeeds for food, and eat holes through them, by which they are ſpoiled from growing. This has often happened to ſeeds which have been ſent me from America.

There are ſeveral of theſe Acacias, which are very tender while they are young; but, after two or three years growth, become hardy enough to bear the open air in ſummer, though ſcarce any of them will live through the winter in a green-houſe, unleſs they have ſome warmth in very cold weather.

Acacia Germanorum. See Prunus Sylveſtris.

Acacia Virginiana. See Robinia.

Acacia, the Three-thorned. See Gleditſia.

MIMULUS. Lin. Gen. Plant. 761. Cynorrhynchium. Mitch. 3.

The Characters are,

The flower hath an oblong, priſmatical, permanent empalement of one leaf; it is of the lip or ringent kind, having one petal, whoſe tube is the length of the empalement, and the brim is divided into two lips. The upper lip is erect, divided at the top into two parts, which are reflexed on their ſide; the lower lip is broad and trifid, the middle ſegment is the leaſt; the palate is convex and bifid. It has four ſlender ſtamina, two longer than the other, terminated by bifid kidney-ſhaped ſummits, and a conical germen ſupporting a ſlender ſtyle, crowned by an oval, bifid, compreſſed ſtigma. The germen afterward turns to an oval capſule with two cells, filled with ſmall ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's fourteenth claſs, which includes thoſe plants whoſe flowers have two long and two ſhort ſtamina, and their ſeeds are included in the capſule.

We know but one Species of this genus at preſent in England, viz.

Mimulus (*Ringens*) erectus, foliis oblongis linearibus ſeſſilibus. Hort. Upſal. 176. tab. 2. *Upright Mimulus with oblong linear leaves ſitting cloſe to the ſtalk.* Digitalis perfoliata glabra, flore violaceo minore. Mor. Hiſt. 2. p. 479. *Smooth perfoliated Foxglove, with a ſmall Violet flower.*

This plant grows naturally in North America in moiſt ground. It has a perennial root and an annual ſtalk, which decays in the autumn; the ſtalk is ſquare, and riſes a foot and a half high, garniſhed at each joint with two oblong ſmooth leaves, which are broadeſt at their baſe, where they almoſt join round the ſtalk, but end in acute points. The lower part of the ſtalk ſends out two or three ſhort branches, and the upper part is adorned with two flowers at each joint, coming from the boſom of the leaves on each ſide the ſtalk; theſe have an oblong curved empalement with five angles, indented at the top into five parts, out of which ariſes the flower, with a long curved tube, ſpreading open at the top into two lips, the upper lip ſtanding erect, which is ſlightly cut into two parts at the top; the under lip turns downward, and is cut into three ſlight ſegments. The flowers are of a Violet colour, but have no ſcent. Theſe appear in July, and are ſucceeded by oblong capſules with two cells, filled with ſmall ſeeds, which in warm ſeaſons ripen in the autumn.

This plant is very hardy in reſpect to cold, but ſhould have a loamy ſoft ſoil, rather moiſt than dry, and not too much expoſed to the ſun. It may be propagated by parting of the roots in the autumn, but the ſlips ſhould not be divided too ſmall; it may alſo be propagated by ſeeds, which ſhould be ſown in autumn, ſoon after they are ripe, for thoſe which are ſown in the ſpring ſeldom grow the ſame year: theſe may be ſown on a border expoſed to the morning ſun, and the plants may be afterward planted in the flower-garden.

MINT. See Mentha.

MIRABILIS. Lin. Gen. Plant. 215. Jalapa. Tourn. Inſt. R. H. 129. tab. 50. Marvel of Peru, or Four o'Clock Flower.

The Characters are,

The empalement of the flower has five, oval, ſpear-ſhaped, ſmall leaves, and is erect, ſwelling, and permanent. The flower has one funnel-ſhaped petal, with a ſlender tube ſitting upon the nectarium, which ſpreads open above, and is cut into five obtuſe ſegments. It hath five ſlender ſtamina, which adhere to the petal, which are unequal and inclined, terminated by roundiſh ſummits, with a roundiſh germen within the nectarium, ſupporting a ſlender ſtyle, crowned by a globular ſtigma. The germen afterward becomes an oval five-cornered nut, incloſing one ſeed.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, which includes thoſe plants whoſe flowers have five ſtamina and one ſtyle.

The Species are,

1. Mirabilis (*Jalapa*) floribus congeſtis terminalibus erectis. Lin. Sp. Plant. 252. *Marvel of Peru, with bunches of flowers erect, terminating the ſtalk.* Admirabilis Peruviana. Cluſ. Hiſt. 2. p. 87.
2. Mirabilis (*Dichotoma*) floribus ſeſſilibus axillaribus erectis ſolitariis. Amœn. Acad. 4. p. 267. *Marvel of Peru, with an erect ſingle flower ſitting cloſe to the wings of the branches.* Jalapa officinarum. Mart. Cent. 1. f. 1. *The then ſuppoſed Jalap of the ſhops.*
3. Mirabilis (*Longiflora*) floribus congeſtis terminalibus longiſſimis nutantibus, foliis ſubvilloſis. Act. Holmenſ. 1756. p. 176. *Long-flowered Marvel of Peru, whoſe flowers are in bunches, terminating the ſtalks and nodding, with hairy leaves.* Mirabilis Mexicana. Hern. Mex. 170. f. 2.

The firſt ſort is the Marvel of Peru, which has been many years cultivated in the Engliſh gardens for ornament; of this there are ſeveral varieties, which differ in the colour of their flowers; two of theſe retain their difference, one of them has purple and white flowers, which are variable, ſome of them are plain purple, others are plain white, but moſt of them are variegated with the two colours; and all theſe varieties are frequently upon the ſame plant, and at others on different plants; the other has red and yellow flowers, which are generally mixed in the ſame flowers, but are often with plain flowers of both colours on the ſame plant, intermixed with thoſe which are variegated; but ſome plants have only plain flowers; and I have never found that the ſeeds of the purple and white ſort, ever produced the yellow and red, nor the latter ever vary to the former, and I have conſtantly cultivated both more than forty years; but although theſe do not change from one to the other, yet as there is no other difference between them than in the colour of their flowers, I have not enumerated them as diſtinct ſpecies.

The ſecond ſort is very common in all the iſlands of the Weſt-Indies, where the inhabitants call it the Four o'Clock Flower, from the flowers opening at that time of the day. Of this ſort I have never ſeen any with variable flowers; they are of a purpliſh red colour, and not much more than half the ſize of the other. The ſtalks of this ſort have thick ſwollen joints; the leaves are ſmaller, and the fruit is very rough, ſo there can be no doubt of their being diſtinct ſpecies, for I have never ſeen any alteration in this from ſeed, and I have cultivated it many years. Tournefort was informed by Father Plumier, that the root of this plant was the officinal Jalap, upon which he conſtituted the genus, and gave that title to it; but the late Dr. Houſtoun was fully informed in the Spaniſh Weſt-Indies of the contrary, and brought over a drawing of the plant which was made by a Spaniard at Halapa, and he carried two or three of the plants to Jamaica, where he planted them in a garden, but after he left the iſland they were deſtroyed by hogs: however, he was fully ſatisfied of its being a Convolvulus, which Mr. Ray had many years before given the Jalap the title of, but upon what authority it does not at preſent appear. Some few years after I received three ſeeds of the Jalap from the Spaniſh Weſt-Indies, one of which grew, and became a large plant, having a bulbous root, as large as thoſe of the Jalap which are imported, but the plant produced no flowers in the three years it lived; and in the winter 1739-40 it died, ſince when I have not been able to procure any ſeeds; however, I am fully ſatisfied that the Jalap is a ſpecies of Convolvulus: indeed the roots of the Marvel of Peru are purgative, and when given in a double quantity for a doſe, will anſwer the purpoſe of Jalap.

The third ſort was ſent from Mexico a few years ſince. The ſeeds of this were firſt ſent me from Paris, by Dr. Monier, of the Royal Academy of Sciences, and afterward I had ſome ſent me from Madrid, by Dr. Hortega. The ſtalks of this ſort fall on the ground, if they are not ſupported; theſe grow about three feet long, and divide into ſeveral branches, which are garniſhed with heart-ſhaped leaves, placed oppoſite; theſe, as alſo the ſtalks, are hairy and viſcous, ſticking to the fingers of thoſe that handle them. The flowers come out at the end of the branches; they are white, and have very long ſlender tubes, and a faint muſky odour; theſe are like the other ſorts, cloſely ſhut all the day, but expand every evening when the ſun declines. The ſeeds of this ſort are larger than thoſe of any other ſpecies, and are as rough as thoſe of the ſecond ſort.

The two varieties of the firſt ſort are very ornamental plants in gardens, during the months of July, Auguſt, and September; and if the ſeaſon continues mild, they often laſt till near the end of October. The flowers do not open till toward the evening, while the weather continues warm, but in moderate cool weather, when the ſun is obſcured, they continue open almoſt the whole day. The flowers are ſo plentifully produced at the ends of the branches, as that when they are open, the plants ſeem entirely covered with them, and there being ſome plain, and others variegated on the ſame plants, they make a fine appearance. The plants are propagated by ſeeds, in the choice of which there ſhould be care taken not to ſave any from thoſe plants whoſe flowers are plain; and thoſe who are deſirous of having only the variegated kinds, are careful to pull off all the plain flowers from thoſe plants which they intend for ſeeds, to prevent them from bearing any ſeeds; by this method they rarely have any plants with plain flowers.

The ſeeds ſhould be ſown on a moderate hot-bed in March, and when the plants come up, they ſhould have plenty of air admitted to them, when the weather is mild, to prevent their being drawn up weak; and when they are about two inches high, they ſhould be tranſplanted on another very moderate hot-bed; or if they are each planted in a ſmall pot filled with light earth, and plunged into a moderate hot-bed, it will be a more ſecure way, for then there will be no danger in ſhaking them out of the pots, when they are to be planted in the borders, ſo as to preſerve all the earth to their roots; by this method, they will not require to be ſhaded, whereas thoſe that are to be tranſplanted from the ſecond hot-bed to the borders, often riſe with little earth to their roots, ſo muſt be carefully ſhaded, otherwiſe they often miſcarry.

When they are in the ſecond hot-bed, they ſhould be ſhaded till they have taken freſh root, after which they muſt have plenty of free air admitted to them to prevent their being drawn up weak, and in May they muſt be gradually inured to the open air. The beginning of June, if the ſeaſon is favourable, they ſhould be tranſplanted into the borders of the pleaſure-garden, giving them proper room, and after they have taken new root, they will require no further care. If theſe ſeeds are ſown in a warm border the beginning of April, they will grow very well, but the plants will be late in the ſeaſon before they flower.

As the ſeeds of theſe plants ripen very well every year, ſo there are not many who are at the trouble of preſerving their roots; but if theſe are taken out of the ground in autumn, and laid in dry ſand all the winter, ſecured from froſt, and planted again in the ſpring, they will grow much larger, and flower earlier than the ſeedling plants: or if the roots are covered in winter with tanners bark to keep out the froſt, they may remain in the borders, provided the ſoil be dry. If the roots which are taken out of the ground, are planted the following ſpring in large pots, and plunged into a hot-bed, under a deep frame, they may be brought forward, and raiſed to the height of four or five feet, as I have frequently practiſed; and theſe plants have come earlier in the ſeaſon to flower, ſo have been intermixed with other ornamental plants, to decorate halls and ſhady courts, where they have appeared very beautiful.

The other two ſpecies require the ſame treatment, but the ſecond ſort is not quite ſo hardy as the other two, ſo unleſs the plants are brought forward in the ſpring, they will not flower till very late, ſo their ſeeds will not ripen.

MISLETOE. See VISCUM.

MITELLA. Tourn. Inſt. R. H. 241. tab. 126. Lin. Gen. Plant. 496. [ſo called of Mitella, *Lat.* a little mitre, becauſe the ſeed-veſſel of this plant reſembles a biſhop's mitre.] Baſtard American Sanicle.

The CHARACTERS are,

The flower has a bell-ſhaped empalement of one leaf, cut into five points, which is permanent. It hath five petals, ending in many hairy points, and are inſerted in the empalement, as are alſo the ten awl-ſhaped ſtamina, which are ſhorter than the petals, and terminated by roundiſh ſummits. It hath a roundiſh germen, which is bifid, with ſcarce any ſtyle, crowned by two obtuſe ſtigmas. The empalement afterward becomes an oval capſule with one cell, opening with two valves, filled with ſmall ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's tenth claſs, which contains thoſe plants whoſe flowers have ten ſtamina and two ſtyles or ſtigmas.

The SPECIES are,

1. MITELLA (*Diphylla*) ſcapo diphyllo. Lin. Gen. Nov. 29. *Mitella with flower-ſtalks having two leaves.* Mi-

tella Americana, florum petalis fimbriatis. Tourn. Inſt. 242. *American Mitella with fringed petals to the flowers.*

2. Mitella (*Nuda*) ſcapo nudo. Amœn. Acad. 2. p. 252. *Mitella with a naked ſtalk.*

The firſt ſort grows naturally in the woods, in moſt parts of North America. It has a perennial root, from which come out many heart-ſhaped angular leaves, ſome of which are obtuſe, and others end in acute points; they are indented on their edges, and of a lucid green, a little hairy, and ſtand upon pretty long foot-ſtalks. The flower-ſtalks ariſe immediately from the root, having two or three angular leaves toward the bottom, and about the middle of the ſtalk come out two ſmall leaves with acute angles, placed oppoſite. The ſtalks riſe eight or nine inches high, and are terminated by a looſe ſpike of ſmall whitiſh flowers, whoſe petals are fringed on their edges; theſe appear the beginning of June, and are ſucceeded by roundiſh capſules filled with ſmall ſeeds.

The ſecond ſort grows naturally in the northern parts of Aſia; this is of a humbler growth than the firſt, ſeldom riſing more than five or ſix inches high. The leaves are not ſo angular as thoſe of the firſt ſort, and the flower-ſtalks are always naked, having no leaves. The ſpikes of flowers are ſhorter, and more compact.

Both theſe are propagated by parting of their roots; the beſt time for this is in autumn: they ſhould be planted in a ſhady ſituation, and they love a ſoft loamy ſoil.

MITELLA MAXIMA. See Bixa.

MOLDAVICA. See Dracocephalum.

MOLLE. See Schinus.

MOLLUGO. Lin. Gen. Plant. 99.

The Characters are,

The empalement of the flower is compoſed of five oblong ſmall leaves, which are coloured on their inſide, and is permanent. The flower has five oval petals, which are ſhorter than the empalement, and three briſtly ſtamina, which ſtand near the ſtyle, and are terminated by ſingle ſummits, with an oval germen having three furrows, ſupporting three very ſhort ſtyles, crowned by obtuſe ſtigmas. The germen afterward becomes an oval capſule with three cells, filled with ſmall kidney-ſhaped ſeeds.

This genus of plants is ranged in the third ſection of Linnæus's third claſs, which includes thoſe plants whoſe flowers have three ſtamina and three ſtyles.

The Species are,

1. Mollugo (*Verticillata*) foliis verticillatis cuneiformibus acutis, caule ſubdiviſo decumbente, pedunculis unifloris. Hort. Upſal. 24. *Mollugo with acute wedge-ſhaped leaves, growing in whorls, a trailing divided ſtalk, and foot-ſtalks bearing a ſingle flower.* Alſine procumbens, galii facie Africana. Hort. Lugd. *Trailing African Chickweed, with the appearance of Ladies Bedſtraw.*

2. Mollugo (*Quadrifolia*) foliis quaternis obovatis, paniculâ dichotomâ. Hort. Cliff. 28. *Moluggo with four leaves at each joint, which are almoſt oval, and a panicle ariſing at the diviſion of the branches.* Herniaria alſines folio. Tourn. Inſt. 507. *Rupturewort with a Mouſe Ear leaf.*

There are two or three ſpecies of this genus, which are rarely admitted into gardens, ſo I have not enumerated them here.

Both theſe ſorts are annual; the firſt is a native of warm countries, ſo is leſs hardy than the ſecond; they are both trailing plants, whoſe ſtalks lie flat on the ground; the firſt ſpreads out eight or nine inches every way, and at each joint is garniſhed with ſix or ſeven ſmall leaves ſpread out in form of a ſtar. The flowers are ſmall, like thoſe of Chickweed, one ſtanding upon each foot-ſtalk; theſe are ſucceeded by oval capſules filled with ſmall ſeeds, which, if permitted to ſcatter, the plants will come up the following ſpring without any care; but when the ſeeds happen to fall upon earth which is thrown upon a hot-bed, the plants will be forwarder and ſtronger than thoſe in the open air. This is preſerved in ſome gardens for the ſake of variety, but has no great beauty.

MOLUCCELLA. Lin. Gen. Plant. 643. Molucca. Tourn. Inſt. R. H. 187. tab. 88. [This plant takes its name from the Molucca Iſlands, becauſe it was found there.] Molucca Balm.

The Characters are,

The flower hath a large permanent empalement of one leaf, which is deeply indented at the brim, where it ſpreads open. The flower is of the lip kind, with a ſhort tube and chaps. The upper lip is erect, concave, and entire. The under lip is trifid, the middle ſegment being longer than the other. It has four ſtamina ſituated under the upper lip, two of which are ſhorter than the other, crowned by ſingle ſummits, and a germen with four parts, ſupporting a ſtyle ſituated with the ſtamina, crowned by a bifid ſtigma. The germen afterward turns to four angular convex ſeeds, ſitting in the empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's fourteenth claſs, which includes thoſe plants whoſe flowers have two long and two ſhort ſtamina, and are ſucceeded by naked ſeeds in the empalement.

The Species are,

1. Moluccella (*Lævis*) calycibus campaniformibus ſubquinquedentatis, denticulis æqualibus. Lin. Sp. 821. *Molucca Balm with bell-ſhaped empalements, indented in five equal parts.* Molucca lævis. Dod. Pempt. 92. *Smooth Molucca Balm.*

2. Moluccella (*Spinoſa*) calycibus ringentibus octodentatis. Lin. Sp. 821. *Molucca Balm whoſe empalements are ringent, indented in eight parts.* Molucca ſpinoſa. Dod. Pempt. 92. *Prickly Molucca Balm.*

The firſt ſort riſes with a ſquare ſtalk three feet high, ſpreading out into many branches, which are ſmooth, and come out by pairs, garniſhed with roundiſh leaves, which are deeply notched on their edges, ſtanding upon long foot-ſtalks placed oppoſite; they are ſmooth, of a light green on both ſides, and at the baſe of their foot-ſtalks the flowers come out in whorls; theſe have very large ſpreading empalements, which are indented in five parts, and immediately under them come out two bunches of pretty long ſpines, one on each ſide the ſtalk, each bunch conſiſting of five or ſix ſpines ariſing from the ſame point. The flowers are ſmall, and being ſituated at the bottom of the large empalements, are not viſible at a diſtance; they are white, with a caſt of purple, and ſhaped like thoſe of the other lip flowers, having the upper lip entire, and hollowed like a ſpoon, and the under lip is cut into three ſegments, the middle one being the longeſt. After the flower is paſt, the germen turn to four club-ſhaped angular ſeeds incloſed in the empalement. It flowers in July, but unleſs the ſeaſon proves warm and dry, the ſeeds do not ripen in England. The ſmell of this plant is to ſome perſons very diſagreeable, and to others very pleaſant.

The ſecond ſort hath ſquare ſmooth ſtalks, of a purpliſh colour, which riſe four feet high, and branch out in the ſame manner. The leaves are ſmaller, and ſtand upon ſhorter foot-ſtalks; they are deeper, and more acutely indented on their edges. The empalements of the flowers are not ſo large, and are cut into eight ſegments, each being terminated by an acute ſpine. The flowers are like thoſe of the former ſpecies, as are alſo the ſeeds; this is not ſo hardy as the firſt ſort.

The firſt grows naturally in ſeveral parts of Syria, and the ſecond is a native of the Molucca Iſlands, from whence this genus received its title. They are both annual plants, which decay ſoon after their ſeeds are ripe, and being natives of warm countries, they ſeldom perfect their ſeeds in England, when they are ſown in the ſpring; therefore the beſt way is to raiſe the plants in autumn, and plant them in ſmall pots; theſe ſhould be placed under a hot-bed frame in winter, where they may have free air in mild weather, by taking off the glaſſes, but covered in froſty weather, obſerving to keep them pretty dry, otherwiſe they are very ſubject to rot, when they are cloſely covered in froſty weather. In the ſpring the plants may be turned out of the pots, with all the earth about their roots, and planted in a warm border, defended from ſtrong winds, giving them a little water to ſettle the earth to their roots; after this they will require no other care but to keep them clean from weeds, and to ſupport them with ſtakes, to prevent their being broken by the winds. The plants thus preſerved through the winter, will flower the latter end of June, ſo from theſe good ſeeds may be expected.

MOLY. See Allium.

MOMORDICA. Tourn. Inſt. R. H. 103. tab. 29, 30. Lin. Gen. Plant. 1090. Male Balſam Apple; in French, *Pomme de Marveille*.

The Characters are,

It hath male and female flowers upon the ſame plant. The male flowers have a ſpreading empalement of one leaf. The flower hath one petal, which adheres to the empalement. It has three ſhort awl-ſhaped ſtamina; in two of the ſtamina the ſummits are bifid, and eared on both ſides; the third has a ſingle eared ſummit; theſe are compreſſed in a body. The female flowers have the ſame empalement and petal as the male, but ſit upon the germen; theſe have three ſhort filaments without ſummits. The germen ſupports one taper trifid ſtyle, crowned by three oblong gibbous ſtigmas. The germen afterward turns to an oblong fruit, opening with an elaſticity, having three membranaceous cells, filled with compreſſed ſeeds.

This genus of plants is ranged in the tenth ſection of Linnæus's twenty-firſt claſs, which contains the plants with male and female flowers on the ſame plant, whoſe ſtamina coaleſce together.

The Species are,

1. Momordica (*Balſamina*) pomis angulatis tuberculatis, foliis glabris patenti-palmatis. Hort. Cliff. 451. *Male Balſam Apple with angular warted fruit, and ſmooth open-handed leaves.* Momordica vulgaris. Tourn. Inſt. R. H. 103. *Common male Balſam Apple.*
2. Momordica (*Charantia*) pomis angulatis tuberculatis, foliis villoſis, longitudinaliter palmatis. Hort. Cliff. 451. *Male Balſam Apple with angular warted fruit, and hairy leaves, which are longitudinally handſhaped.* Momordica Zeylanica, pampineâ fronde, fructu longiori. Tourn. Inſt. R. H. 103. *Male Balſam Apple of Ceylon, with a Vine leaf and a longer fruit.*
3. Momordica (*Zeylanica*) pomis ovatis acuminatis tuberculatis, foliis glabris palmatis ſerratis. *Male Balſam Apple with an oval, acute-pointed, warted fruit, and ſmooth band-ſhaped leaves, which are ſawed.* Momordica Zeylanica, pampineâ fronde, fructu breviori. Tourn. Inſt. 103. *Male Balſam Apple of Ceylon, with a Vine leaf and a ſhorter fruit.*
4. Momordica (*Elaterium*) pomis hiſpidis, cirrhis nullis. Lin. Sp. Plant. 1010. *Male Balſam Apple with a prickly fruit, and no tendrils to the Vines.* Cucumis ſylveſtris aſininus dictus. C. B. P. 314. *Wild Cucumber, called Aſſes Cucumber, and the Elaterium of Boerbaave.*

The firſt ſort grows naturally in Aſia, the ſecond and third in the iſland of Ceylon; they are annual plants, which periſh ſoon after they have ripened their fruit; theſe have trailing ſtalks like thoſe of the Cucumber and Melon, which extend three or four feet in length, ſending out many ſide branches which have tendrils, by which they faſten themſelves to any neighbouring plants, to ſecure themſelves from being toſſed and blown about by the winds, and are garniſhed with leaves ſhaped like thoſe of the Vine. The leaves of the firſt and third ſorts are ſmooth, and deeply cut into ſeveral ſegments, and ſpread open like a hand; but thoſe of the ſecond ſort are extended more in length, and are hairy. The fruit of the firſt ſpecies is oval, ending in acute points, having ſeveral deep angles, which have ſharp tubercles placed on their edges; it changes to a red or purpliſh colour when ripe, opening with an elaſticity, and throwing out its ſeeds.

The fruit of the ſecond ſort is much longer than that of the firſt, and not ſo deeply channelled. The tubercles are ſcattered all over the ſurface, and are not ſharp like thoſe of the other; this fruit is yellow, when ripe, and caſts out its ſeeds with an elaſticity.

The fruit of the third ſort is ſhort and pointed like that of the firſt, but does not ſwell ſo large in the middle. The angles of this are not deep, and the whole ſurface is cloſely ſet with ſharp tubercles; this changes to a deep Orange colour when ripe, and caſts out its ſeeds in the like manner.

The fourth ſort is commonly called Wild or Spurting Cucumber, from its caſting out its ſeeds, together with the viſcid juice in which the ſeeds are lodged, with a violent force, if touched when ripe; and from hence it has ſometimes the appellation of Noli me tangere, or *touch me not*. This plant grows naturally in ſome of the warm parts of Europe, but in England it is cultivated in gardens for the fruit, which is uſed in medicine, or rather the fæcula of the juice of the fruit, which is the Elaterium of the ſhops.

This plant hath a large fleſhy root ſomewhat like that of Briony, from which come forth every ſpring ſeveral thick, rough, trailing ſtalks, which divide into many branches, and extend every way two or three feet; theſe are garniſhed with thick, rough, almoſt heart-ſhaped leaves, of a gray colour, ſtanding upon long foot-ſtalks. The flowers come out from the wings of the ſtalk, theſe are male and female, growing at different places on the ſame plant, like thoſe of the common Cucumber, but they are much leſs, of a pale yellow colour, with a greeniſh bottom: the male flowers ſtand on ſhort thick foot-ſtalks, but the female flowers ſit upon the young fruit, which, after the flower is faded, grows to be an inch and a half long, and ſwelling like a Cucumber, of a gray colour like the leaves, and covered over with ſhort prickles. Theſe do not change their colour when ripe, like moſt of the other fruit of this claſs; but if attempted to be gathered, they quit the foot-ſtalk, and caſt out the ſeeds and juice with great violence; ſo that where any plants are growing, and the fruit permitted to ſtand till it is ripe, the ſeeds will be ſcattered all round to a great diſtance, and there will be plenty of the plants produced the following ſpring.

But when the fruit is deſigned for uſe, it ſhould always be gathered before it is ripe, otherwiſe the greateſt part of the juice will be loſt, which is the only valuable part; for the juice which is expreſſed, with part of the parenchyma of the fruit, is not to be compared with the other for its virtues; for the Elaterium which is made from clear juice of the fruit, is much whiter, and will retain its virtues much longer, than that which is extracted by preſſure.

The three firſt ſorts are annual; their ſeeds muſt be ſown on a hot-bed the beginning of March, and when the plants come up, they ſhould be tranſplanted out into a freſh hot-bed, after the manner of Cucumbers or Melons, putting two plants of the ſame kind under each light, and the plants watered and ſhaded until they have taken root; after which they muſt be treated as Cucumbers, permitting their branches to extend upon the ground in the ſame manner, and obſerve to keep them clear from weeds.

With this management (provided you do not let them have too much wet, or expoſe them too much to the open air) they will produce their fruit in July, and their ſeeds will ripen in Auguſt and September, when you muſt obſerve to gather it as ſoon as you ſee the fruit open, otherwiſe it will be caſt abroad, and with difficulty gathered up again.

Theſe plants are preſerved in curious gardens for the oddneſs of their fruit; but as they take up a great deal of room in the hot-beds, requiring frequent attendance, and being of little beauty or uſe, ſo they are not much cultivated in England, except in botanic gardens for variety.

There are ſome perſons who put theſe plants in pots, and faſten them up to ſtakes, to ſupport the Vines from trailing on the ground, and place the pots in ſtoves; where, when they are ſkilfully managed, they will produce their fruit tolerably well; and in this way they make a better appearance, than when the Vines ſpread on the ground like Cucumbers and Melons. But when the plants ſpread on the ground, which is their natural way of growing, they thrive much better, and produce more fruit, than when they are ſupported; for though theſe plants have claſpers, yet theſe are not formed for climbing, but merely to faſten themſelves about any neighbouring ſupport, to ſecure them from being raiſed by the wind and broken; which would often happen, where they grow in the open air and are fully expoſed, were it not for this ſecurity.

The fourth ſort is eaſily propagated by ſeeds, which (as was before mentioned) if permitted to ſcatter, there will be a ſupply of plants come up the following ſpring; or if the ſeeds are ſown upon a bed of light earth, the plants will come up in about a month after, and may be tranſplanted to an open ſpot of ground, in rows at three or four feet diſtance, and almoſt as far aſunder in the rows; if theſe are carefully tranſplanted while young, there will be little hazard of their growing; and after they have taken new root, they will require no further care, but to keep them clear from weeds. If the ground is dry in which they are planted, the roots will continue three or four years, unleſs the winter ſhould prove very ſevere, which will kill them.

MONARDA. Lin. Gen. Plant. 34. Leonurus. Tourn. Inſt. R. H. 187. tab. 87.

The Characters are,

The flower has a tubulous cylindrical empalement of one leaf, which is channelled, and cut into five equal parts at the brim. The flower hath one petal, and is of the lip kind, having a cylindrical tube longer than the empalement, divided at the top into two lips. The upper lip is narrow, entire, and erect; the under lip is broad, trifid, and reflexed; the middle ſegment being long and narrow, thoſe on the ſide are obtuſe. It hath two briſtly ſtamina the length of the upper lip, in which it is involved, terminated by compreſſed erect ſummits. In the bottom of the tube is ſituated a four-pointed germen, ſupporting a ſlender ſtyle involved with the ſtamina, and crowned by an acute bifid ſtigma. The germen afterward turns to four naked ſeeds, incloſed in the empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's ſecond claſs, which includes the plants whoſe flowers have two ſtamina and one ſtyle.

The Species are,

1. Monarda (*Fiſtuloſa*) capitulis terminalibus, caule obtuſ-angulo. Hort. Upſal. 12. *Monarda with heads of flowers terminating the ſtalks, which have obtuſe angles.* Leonurus Canadenſis, origani folio. Tourn. Inſt. R. H. 187. *Canada Lion's Tail, with an Origanum leaf.*
2. Monarda (*Didyma*) floribus capitatis, ſub-didynamis, caule acutangulo. Lin. Sp. Plant. 32. *Monarda with headed flowers, whoſe ſtamina are almoſt in two bodies, and an acute angular ſtalk.* Monarda floribus capitatis verticillatiſque, caule acutangulo, foliis lanceolato-ſerratis glabris. Butt. Cun. 226. *Monarda with flowers collected in heads and whorls, an acute-angular ſtalk, and ſmooth, ſawed, ſpear-ſhaped leaves, commonly called Oſwego Tea.*
3. Monarda (*Punctata*) floribus verticillatis, corollis punctatis. Hort. Upſal. 12. *Monarda with flowers growing in whorls, whoſe petals are ſpotted.* Clinopodium Virginianum, anguſtifolium, floribus amplis luteis, purpurâ maculâ notatis, cujus caulis ſub quovis verticillo decem vel duodecim foliolis rubentibus eſt circumcinctis. Baniſt. Raii Sup. 300. *Narrow-leaved Field Baſil of Virginia, with large yellow flowers ſpotted with purple, whoſe ſtalks have ten or twelve rediſh leaves under each whorl of flowers.*

The firſt ſort grows naturally in Canada, and many other parts of North America. It hath a perennial root, compoſed of many ſtrong fibres, which ſpread far on every ſide. The ſtalks riſe near three feet high, which are hairy, and have obtuſe angles; theſe ſend out two or four ſmall ſide branches toward the top, garniſhed with oblong leaves, broad at their baſe, but terminate in acute points; they are hairy, a little indented on their edges, ſtanding on ſhort hairy foot-ſtalks, and are placed oppoſite. The ſtalk and branches are terminated by heads of purple flowers, which have a long involucrum, compoſed of five acute-pointed leaves. The flowers have each two ſtamina which are longer than the petal, with a ſtyle of the ſame length, crowned by a bifid ſtigma. The flowers appear in July, and are ſucceeded by ſeeds which ripen in the autumn.

The ſecond ſort grows naturally in North America, where the inhabitants frequently uſe the leaves for tea, ſo it is commonly called Oſwego Tea, by which title it was brought to England. This hath a perennial root and an annual ſtalk, which decays every autumn. The ſtalks of this ſort are ſmooth, having four acute angles; they riſe about two feet high, and are garniſhed with ſmooth, oval, ſpear-ſhaped leaves, which are indented on their edges, and ſtand oppoſite on very ſhort foot-ſtalks; theſe when bruiſed, emit a very grateful refreſhing odour; the ſtalks ſend out toward their top two or four ſmall ſide branches, which are garniſhed with ſmall leaves of the ſame ſhape with the other. The flowers are produced in large heads or whorls at the top of the ſtalk, and there is often a ſmaller whorl of flowers, growing round the ſtalk at a joint below the head; and out of the head ariſes a naked foot-ſtalk, ſuſtaining a ſmall head or whorl of flowers: the flowers are of a bright red colour; they have two lips, the upper lip is long, narrow, and entire, the under lip is cut into three parts; they have each two ſtamina which are longer than the petal, terminated by compreſſed ſummits, and many of them have two ſhorter ſtamina, without ſummits. The plant flowers in July, but in a moiſt ſeaſon, or when the plants are in a moiſt ſoil, they will continue in flower till the middle or latter end of September.

Both theſe ſorts may be propagated by parting of their roots; the firſt does not multiply ſo faſt as the ſecond, but as that produces plenty of ſeeds, ſo it may be eaſily propagated that way. If the ſeeds are ſown in the autumn ſoon after they are ripe, the plants will come up the following ſpring; but if they are not ſown till ſpring, the plants ſeldom riſe till the next year. When the plants are come up and are fit to remove, they ſhould be tranſplanted into a ſhady border about nine inches diſtance, and when they have taken new root, they will require no other care but to keep them clean from weeds till the autumn, when they ſhould be tranſplanted into the borders where they are to remain. The following ſummer they will flower and produce ripe ſeeds, but the roots will continue ſeveral years, and may be parted every other year to increaſe them. This loves a ſoft loamy ſoil, and a ſituation not too much expoſed to the ſun.

The ſecond ſort ſeldom ripens ſeeds in England, but it increaſes faſt enough by its creeping roots, as alſo by ſlips or cuttings, which, if planted in a ſhady border in May, will take root in the ſame manner as Mint or Balm; but as the roots multiply ſo faſt, there is ſeldom occaſion to uſe any other method to propagate them.

This ſort loves a moiſt light ſoil, and in a ſituation where the plants have only the morning ſun, they will continue longer in flower than thoſe which are expoſed to the full ſun. This is a very ornamental plant in gardens, and the ſcent of the leaves is very refreſhing and agreeable to moſt people, and ſome are very fond of the tea made with the young leaves.

The third ſort grows naturally in North America; this is a biennial plant, and probably in its native country may be an annual, for the roots periſh after the plants have perfected their ſeeds. This hath ſquare ſtalks which riſe about two feet high, branching out from the bottom to the top, and are garniſhed with ſpear-ſhaped leaves, which come out in cluſters at each joint, where there are two larger leaves placed oppoſite, and ſeveral ſmaller come out on each ſide the ſtalk; the larger leaves are about two inches and a half long, and three quarters of an inch broad, and are ſlightly indented on their edges. Toward the upper part of their ſtalk the flowers come out in large whorls, having to each whorl an involucrum, compoſed of ten or twelve ſmall ſpear-ſhaped leaves, of a purpliſh red colour on their upper ſide; the flowers are pretty large, of the ſame form with thoſe of the other ſorts, of a dirty yellow colour ſpotted with purple; they have each two long ſtamina ſituated under the upper lip, which are terminated by bifid compreſſed ſummits, and are ſucceeded by four naked ſeeds incloſed in the empalement. It flowers in July, and if the ſummer proves favourable, the ſeeds ſometimes ripen in the autumn.

This plant is propagated by ſeeds, which, if ſown on a border of light earth expoſed to the eaſt, the plants will riſe very freely; when they are fit to remove, they may be tranſplanted into a ſhady border, in the ſame manner as hath been directed for the firſt ſort; and if they ſhould ſhoot up ſtalks to flower, they ſhould be cut down to ſtrengthen the roots, that they may put out lateral buds, for when they are permitted to flower the firſt year, the roots ſeldom live through the winter, therefore they ſhould be prevented: in the autumn the plants may be removed, and planted in the open borders of the pleaſure-garden, where they will flower the following ſummer; and if the ſeaſon ſhould prove dry, they ſhould be duly watered, otherwiſe they will not be near ſo beautiful, nor will the plants produce good ſeeds.

MONBIN. See Spondias.

MONTIA. See Heliocarpus.

MORÆA. Lin. Gen. Plant. 60.

The Characters are,

The ſheath of the flower has two valves; the flower is compoſed of ſix petals, the three upper are erect and bifid, the three under ſpread open; it hath three ſhort ſtamina, terminated by oblong ſummits. The germen is ſituated below the flower, ſupporting a ſingle ſtyle, crowned by a trifid erect ſtigma. The germen afterward becomes a three-cornered capſule, having three furrows, with three cells, containing ſeveral round ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's third claſs, intitled Triandria Monogynia, the flower having three ſtamina and one ſtyle.

The Species are,

1. Moræa (*Vegeta*) ſpatha uniflora, foliis gladiolatis. *Morea with one flower in each ſheath, and ſword-ſhaped leaves.* Moræa foliis canaliculatis. Lin. Sp. 59. *Morea with channelled leaves.*
2. Moræa (*Juncea*) ſpatha biflora, foliis ſubulatis. *Morea with two flowers in each ſheath, and awl-ſhaped leaves.* Moræa foliis ſubulatis. Lin. Sp. 59. *Morea with awl-ſhaped leaves.*

Theſe plants are both natives of the Cape of Good Hope, from whence I received their ſeeds, which have ſucceeded in the Chelſea garden, where the plants have ſeveral times produced their flowers, which differing from all the other genera of plants in the ſame claſs, I have taken the liberty of titling it Morea, in honour of Robert More, Eſq; of Shrewſbury, who is well ſkilled in the ſcience of botany, and alſo in other parts of natural hiſtory.

The firſt ſort has fibrous roots like thoſe of the Flag-leaved Iris, from whence ariſes many ſmall ſword-ſhaped leaves, five or ſix inches long, and half an inch broad in the middle, diminiſhing toward both ends, of a deep green colour, lying over each other at their baſe, in the ſame manner as the Iris; the flower-ſtalk ariſes between the leaves from the root, about eight inches high, having one ſmall leaf at each joint, and is terminated by one flower, which is covered with a ſpatha (or ſheath) having two valves; the flower is of a dirty white, each petal having a bluſh of purple toward their upper part, and a pretty broad ſpot of yellow toward their tails; within are three ſlender ſtamina terminated by oblong ſummits, and one ſtyle crowned by a trifid ſtigma. The flowers appear in June, and the ſeeds ripen the end of July.

The ſecond ſort hath a ſmall bulbous root, a little compreſſed on the ſides, with a ſmooth dark-coloured ſkin, from which ariſe three or four awl-ſhaped leaves of a pale green, ſome of which are five inches long, and others are ſeven or eight, and about half an inch broad, terminating with three angles; the foot-ſtalks of the flowers riſe about ſix inches high, and generally bend at their lower joint; theſe are garniſhed with a ſmall leaf at each joint, whoſe baſe almoſt ſurrounds the ſtalk, which is terminated by two flowers, encompaſſed with a withered ſheath; the flowers are of an Orange colour; the petals are pretty broad upward, but are connected at their baſe. Theſe appear in June, and the ſeeds ripen the end of July.

The plants are propagated either by ſeeds, or from offſets of the ſecond ſort, and by parting or dividing the roots of the firſt; the beſt time for tranſplanting of them, and ſeparating the offſets of the ſecond ſort, and parting the roots of the firſt, is in Auguſt, that they may put out new fibres before winter; and that is alſo the right ſeaſon for ſowing of the ſeeds, for when they are ſown at this time of the year in ſmall pots, and plunged into a bed of old tanners bark, under a common frame in winter, there is little danger of theſe ſeeds miſcarrying. The plants will alſo require this ſort of ſhelter in winter, for as they are too tender to thrive in the open air in England, and if they are placed in a green-houſe, they are apt to draw up weak, therefore when they are ſheltered under a frame, ſo as to enjoy the free open air in winter when the weather is warm, and ſecured from froſt and hard rains, they will flower and ripen their ſeeds better than with any other management: in ſummer they ſhould be fully expoſed to the open air till October, when they ſhould be removed into ſhelter.

MORINA. Tourn. Cor. 48. tab. 480. Lin. Gen. Plant. 39. Diototheca. Vaill. Mem. Acad. 1722.

The Characters are,

It hath a double empalement; that under the fruit is tubulous, cylindrical, of one leaf, indented at the brim, and permanent; that of the flower is tubulous, bifid, of one leaf, and permanent. The flower hath one petal, with a long tube enlarged upward, and a little incurved. The top is divided into two lips; the upper lip is ſmall and bifid, the under lip is cut into three equal obtuſe ſegments, the middle one being extended beyond the other. It hath two briſtly ſtamina ſituated near the ſtyle, terminated by heart-ſhaped erect ſummits. The globular germen is ſituated under the flower, ſupporting a ſlender ſtyle which is longer than the ſtamina, crowned by a target-ſhaped ſtigma; the germen afterward becomes a ſingle ſeed, crowned by the empalement of the flower.

This genus of plants is ranged in the firſt ſection of Linnæus's ſecond claſs, which contains thoſe plants whoſe flowers have two ſtamina and one ſtyle.

There is but one Species of this genus at preſent known, which is,

Morina (*Orientalis.*) Hort. Cliff. 14. Morina Orientalis, carlinæ folio. Tourn. Cor. *Eaſtern Morina, with a Carline Thiſtle leaf.*

This plant was diſcovered by Dr. Tournefort, in his travels in the Levant, who gave it this name in honour of Dr. Morin, a phyſician at Paris.

It grows naturally near Erzeron in Perſia, and was in the Engliſh gardens before the ſevere winter in 1740, which killed all the plants that were here, alſo thoſe in the garden at Paris; ſo the only plant remaining was in the garden of Monſieur du Hamel. The root of this plant is taper and thick, running deep into the ground, ſending out ſeveral thick ſtrong fibres as large as a finger; the ſtalk riſes near three feet high; it is ſmooth, of a purpliſh colour toward the bottom, but hairy and green at the top, garniſhed at each joint by three or four prickly leaves like thoſe of the Carline Thiſtle; they are four or five inches long, and an inch and a half broad, of a lucid green on their upper ſide, but of a pale green on their under, and a little hairy, armed on their edges with ſpines. The flowers come out from the wings of the leaves on each ſide the ſtalk; theſe have very long tubes, which are ſlender at the bottom, but are enlarged upward, and are a little incurved; the brim ſpreads open with two large lips, the upper lip is indented at the top and rounded, the lower lip is cut into three obtuſe ſegments; under the lip are ſituated two briſtly ſtamina which are crooked, and crowned with yellow ſummits. Theſe flowers appear in July, but I never had any ſeeds ſucceed them. Some of the flowers are white, and others of a purpliſh red on the ſame plant.

This plant is propagated by ſeed, which ſhould be ſown ſoon after it is ripe in the autumn, otherwiſe the plants will not come up the following ſummer; for I have ſeveral times obſerved, where the ſeeds have been ſown in the ſpring, they have remained in the ground fourteen or fifteen months before the plants have appeared. Theſe ſeeds ſhould be ſown in the places where the plants are to remain, becauſe they ſend forth tap-roots, which run very deep into the ground; and when theſe are broken or injured in tranſplanting, the plants ſeldom thrive after. They may be ſown in open beds or borders of freſh light earth, being careful to mark the places, that the ground may not be diſturbed; for it frequently happens, that the ſeeds do not come up the firſt year, when they are ſown in autumn; but when they are ſown in the ſpring, they never come up the ſame year. The ground where the ſeeds are ſown muſt be kept clear from weeds, which is all that is neceſſary to be done, until the plants come up; where they are too cloſe together, they ſhould be thinned while young, ſo as to leave them near eighteen inches apart; after which time, they will require no other culture but to keep them conſtantly clear from weeds; and in the ſpring, juſt before the plants put out new leaves, to dig the ground gently between them, and lay a little freſh earth over the ſurface of the bed to encourage them.

In autumn theſe plants decay to the ground, and ſend forth new leaves the following ſpring, but it will be three years from the time of the plants firſt coming up to their flowering, though after that time they will flower every ſeaſon; and the roots will continue many years, provided they are not diſturbed, or killed by very ſevere froſt.

MORUS. Tourn. Inſt. R. H. 589. tab. 363. Lin. Gen. Plant. 936. [of μαυρὸς, black, becauſe its fruit is ordinarily ſo.] The Mulberry-tree; in French, *Murier*.

The Characters are,

It hath male flowers growing at ſeparate diſtances from the female on the ſame tree. The male flowers are collected in long taper ropes or katkins; theſe have no petals, but have four awl-ſhaped erect ſtamina, which are longer than the empalement, terminated by ſingle ſummits. The female flowers are collected into roundiſh heads; theſe have no petals, but a heart-ſhaped germen, ſupporting two long, rough, reflexed ſtyles, crowned by ſingle ſtigmas. The empalement of theſe afterward become large, fleſhy, ſucculent fruit, compoſed of ſeveral protuberances, in each of which is lodged one oval ſeed.

This genus is ranged in the fourth ſection of Linnæus's twenty-firſt claſs, which contains thoſe plants which have male and female flowers at ſeparate diſtances on the ſame plant, and the male flowers have four ſtamina.

The Species are,

1. Morus (*Nigra*) foliis cordatis. Hort. Cliff. 441. *Mulberry with rough heart-ſhaped leaves.* Morus fructu nigro. C. B. P. 459. *Mulberry with a black fruit, or the common Mulberry.*
2. Morus (*Laciniatis*) foliis palmatis hirſutis. *Mulberry with hand-ſhaped hairy leaves.* Morus fructu nigro minori foliis eleganter laciniatis. Tourn. Inſt. R. H. 589. *Smaller black Mulberry with elegant cut leaves.*
3. Morus (*Rubra*) foliis cordatis ſubtus villoſis, amentis cylindricis. Lin. Sp. Plant. 986. *Mulberry with heart-ſhaped leaves which are hairy on their under ſide, and cylindrical katkins.* Morus Virginienſis arbor, loti arboris inſtar ramoſa, foliis ampliſſimis. Pluk. Phyt. tab. 246. fol. 4. *Virginia Mulberry branching like the Nettle-tree, having very large leaves.*
4. Morus (*Alba*) foliis obliquè cordatis lævibus. Hort. Cliff. 441. *Mulberry with oblique, ſmooth, heart-ſhaped leaves.* Morus fructu albo. C. B. P. 459. *Mulberry with a white fruit.*
5. Morus (*Tinctoria*) foliis obliquè cordatis acuminatis hirſutis. *Mulberry with oblique, heart-ſhaped, acute-pointed, hairy leaves.* Morus fructu viridi, ligno ſulphureo tinctorio. Sloan. Hiſt. Jam. 2. p. 3. *Mulberry with a green fruit, whoſe wood dyes a ſulphur colour, or Fuſtick wood.*
6. Morus (*Papyrifera*) foliis palmatis, fructibus hiſpidis. Lin. Sp. Plant. 986. *Mulberry with hand-ſhaped leaves and prickly fruit.* Morus ſativa, foliis urticæ mortuæ, cortice papyrifera. Kæmp. Amœn. 471. *Cultivated Mulberry with leaves like Dead Nettle, and of whoſe bark paper is made.*
7. Morus (*Tatarica*) foliis ovato-oblongis utrinque æqualibus, inæqualiter ſerratis. Flor. Zeyl. 337. *Mulberry with oval oblong leaves, which are equal on both ſides, but unequally ſawed.* Tinda-parua. Hort. Mal. 1. p. 87. fol. 49.
8. Morus (*Zanthoxylum*) foliis ovato-oblongis acuminatis obliquis, ramis aculeatis. *Mulberry with oval, oblong, acute-pointed leaves, which are oblique to the foot-ſtalk, and prickly branches.* Zanthoxylum aculeatum, carpini foliis, Americanum, cortice cinereo. Pluk. Phyt. 239. fol. 3. *Prickly Zanthoxylum of America, with Hornbeam leaves and an Aſh-coloured bark.*

The firſt ſort is the common black Mulberry-tree, which is cultivated for the delicacy of its fruit. This tree grows naturally in Perſia, from whence it was firſt brought to the ſouthern parts of Europe, but is now become common in every part of Europe, where the winters are not very ſevere; for in the northern parts of Sweden, theſe trees will not live in the open air; and in ſeveral parts of Germany they are planted againſt walls, and treated in the ſame way as Peach, and other tender fruits are here.

Theſe trees are generally of both ſexes, having male flowers or katkins on the ſame tree with the fruit; but it often happens, that ſome of the trees which are raiſed from ſeeds, have generally male flowers, and produce no fruit; ſo that thoſe who plant theſe trees for their fruit, ſhould never make choice of ſuch as have been propagated by ſeeds, unleſs they have ſeen them produce fruit in the nurſery. It is alſo the ſureſt way to mark ſuch trees as are fruitful in the nurſery, at the time when their fruit is upon them, becauſe thoſe trees which are propagated by layers, are ſometimes of the male ſort; for I have ſeveral times obſerved, that ſome of the large branches of theſe trees have produced only katkins, when the other parts of the trees have been very fruitful; ſo that unleſs care is taken in the choice of the branches for making the layers, there is the ſame hazard as in ſeedling trees: nor ſhould the ſhoots which come out near the roots of old trees be ever laid down, for theſe rarely produce fruit until they have been planted many years, although the trees from which theſe were produced might be very fruitful. I have obſerved ſome trees which produced only katkins for many years after they were planted, and afterward have become fruitful; the ſame I have obſerved in Walnut-trees, and my honoured friend the Chevalier Rathgeb, has informed me, that he has obſerved the ſame in the Lentiſk and Turpentine-trees.

The old Mulberry-trees are not only more fruitful than the young, but their fruit are much larger and better flavoured; ſo that where there are any of theſe old trees, it is the beſt way to propagate from them, and to make choice of thoſe branches which are moſt fruitful. The uſual method of propagating theſe trees, is by laying down their branches, which will take root in one year, and are then ſeparated from the old trees; but as the moſt fruitful branches are often ſo far from the ground as not be layed, unleſs by raiſing of boxes or baſkets of earth upon ſupports for this purpoſe, ſo the better way is to propagate them by cuttings, which, if rightly choſen and ſkilfully managed, will take root very well; and in this method there will be no difficulty in having them from trees at a diſtance, and from the moſt fruitful branches. Theſe cuttings ſhould be the ſhoots of the former year, with one joint of the two years wood to their bottom; the cuttings ſhould not be ſhortened, but planted their full length, leaving two or three buds above ground. The beſt ſeaſon for planting them is in March, after the danger of hard froſt is over; they ſhould be planted in light rich earth, preſſing the ground pretty cloſe about them; and if they are covered with glaſſes, it will forward their putting out roots; but where there is not ſuch conveniency, the ground about them ſhould be covered with moſs, to prevent its drying; and where this is carefully done, the cuttings will require but little water, and will ſucceed much better than with having much wet. If the cuttings ſucceed well and make good ſhoots, they may be tranſplanted the following ſpring into a nurſery, where they ſhould be regularly trained to ſtems, by fixing down ſtakes by each, to which the principal ſhoots ſhould be faſtened; and moſt of the lateral branches ſhould be cloſely pruned off, leaving only two or three of the weakeſt to detain the ſap, for the augmentation of the ſtem; for when they are quite diveſted of their ſide ſhoots, the ſap is mounted to the top, ſo that the heads of the trees grow too faſt for the ſtems, and become too weighty for their ſupport. In about four years growth in the nurſery, they will be fit to tranſplant where they are to remain; for theſe trees are tranſplanted with greater ſafety while young, than when they are of a large ſize.

If the cuttings are planted in a bed fully expoſed to the ſun, it will be proper to arch the bed over with hoops, that they may be ſhaded with mats in the heat of the day during the ſpring, till they have put out roots; after which, the more they are expoſed to the ſun, the better they will ſucceed, provided the ground is covered with moſs or mulch to prevent its drying, for the ſun will harden the ſhoots, and thereby they will be in leſs danger of ſuffering by the early froſts in autumn; for when theſe are in a ſhady ſituation, they are apt to grow vigorouſly in ſummer, ſo will be replete with moiſture, and the early froſts in October frequently kill their tops; and if the following winter proves ſevere, they are often killed to their roots, and ſometimes are entirely deſtroyed. I have two or three times made trial of planting the cuttings of Mulberries on a hot-bed, and have found them ſucceed extremely well. This I was led to by obſerving ſome ſticks of Mulberry-trees which were cut for forks, and thruſt into the hot-bed to faſten down the Vines of Cucumbers; which, although they had been cut from the tree a conſiderable time, yet many of them put out roots and ſhot out branches; ſo that where any perſon is in haſte to propagate theſe trees, if the cuttings are planted on a moderate hot-bed, they will take root much ſooner than in the common ground.

This tree delights to grow in rich light earth, ſuch as is in moſt of the old kitchen-gardens about London, where there is alſo a great depth of earth; for in ſome of thoſe gardens there are trees of a very great age, which are very healthy and fruitful, and their fruit is larger and better flavoured than thoſe of younger trees. I have never yet ſeen any of theſe trees which were planted in a very ſtiff ſoil, or on ſhallow ground, either upon clay, chalk, or gravel, which have been healthy or fruitful, but their ſtems and branches are covered with moſs, ſo that the little fruit which they ſometimes produce are ſmall, ill taſted, and late before they ripen.

If theſe trees are planted in a ſituation where they are defended from the ſtrong ſouth and north-weſt winds, it will preſerve their fruit from being blown off; but this ſhelter, whether it be trees or buildings, ſhould be at ſuch a diſtance as not to keep off the ſun; for where the fruit has not the benefit of his rays to diſſipate the morning dews early, they will turn mouldy and rot upon the trees. There is never any occaſion for pruning theſe trees, more than to cut off any of the branches which may grow acroſs others, ſo as to rub and wound their bark, by their motion occaſioned by the wind; for their ſhoots ſhould never be ſhortened, becauſe the fruit is produced on the young wood.

The ſecond ſort grows naturally in Sicily, from whence I received a parcel of the ſeeds, and raiſed a good number of the plants; all theſe were totally different in their leaves from the common Mulberry, ſo that I am certain of its being a diſtinct ſpecies. It is alſo a tree of humbler growth, but the fruit is ſmall and has no flavour, ſo is not worth propagating; ſome of the trees produced fruit two or three years in the Chelſea garden.

The white Mulberry is commonly cultivated for its leaves to feed ſilk-worms in France, Italy, &c. though the Perſians generally make uſe of the common black Mulberry for that purpoſe; and I have been aſſured by a gentleman of honour, who has made trial of both ſorts of leaves, that the worms fed with thoſe of the black ſort produce much better ſilk than thoſe fed with the white; but he obſerves that the leaves of the black ſort ſhould never be given to the worms after they have eaten for ſome time of the white, leſt the worms ſhould burſt, which is often the caſe when they are thus treated.

The trees which are deſigned to feed ſilk-worms, ſhould never be ſuffered to grow tall, but rather kept in a ſort of hedge; and inſtead of pulling off the leaves ſingly, they ſhould be ſheared off together with their young branches, which is much ſooner done, and not ſo injurious to the tree.

This white ſort may be propagated either from ſeeds or layers, as the black Mulberry, and is equally hardy; but the moſt expeditious method of raiſing theſe trees in quantity, is from the ſeeds, which may be procured in plenty from the ſouth of France or Italy: the beſt way to ſow theſe ſeeds in England, is to make a moderate hot-bed, which ſhould be arched over with hoops, and covered with mats; upon this bed the ſeeds ſhould be ſown in the end of March, and covered over with light earth about a quarter of an inch deep: in very dry weather the bed muſt be frequently watered, and in the heat of the day ſhaded with mats, and alſo covered in the nights when they are cold; with this management the plants will come up in five or ſix weeks, and as they are tender when they firſt appear, ſo they muſt be guarded againſt froſty mornings, which often happen in May, and deſtroy ſuch tender plants; during the ſummer they muſt be kept clean from weeds, which is all the culture they require: but there muſt be care taken of them the firſt winter, eſpecially to cover them in autumn, when the firſt froſts come, which will kill the tender plants to the ground, if they are not protected; the following March theſe plants ſhould be tranſplanted into the nurſery to get ſtrength, where they may remain two or three years, and then ſhould be removed where they are to continue.

There are two or three varieties of this tree, which differ in the ſhape of their leaves, ſize, and colour of their fruit; but as they are of no other uſe than for their leaves, the ſtrongeſt ſhooting and the largeſt leaved ſhould be preferred.

The third ſort, which is the large-leaved Virginian Mulberry with black ſhoots, is more uncommon than either of the former; there is a large tree of this growing in the gardens of the Biſhop of London at Fulham, which has been ſeveral years an inhabitant of that garden, but has never produced any fruit that I could learn, but hath ſome years a great number of katkins, much like thoſe of the Hazel-nut, which occaſioned Mr. Ray to give it the name of Corylus; but it may be one of the male trees which do not produce fruit, as it ſometimes happens in the common ſorts of Mulberries; the leaves of this are ſomewhat like thoſe of the common Mulberry-tree, but are rougher.

This tree has not been propagated yet in this country, for though it has been budded and grafted upon both the black and white Mulberries, yet I cannot hear that it hath ſucceeded upon either, ſo that I ſuſpect it is not of this genus; and the tree being pretty tall, cannot be laid down, which is the moſt likely method to propagate it. This is very hardy, and will endure the cold of our climate in the open air very well, and is coveted as a curioſity by ſuch as delight in a variety of trees and ſhrubs.

The fifth ſort is the tree whoſe wood is uſed by the dyers, and is better known by the title of Fuſtick, which is given to the wood, than by its fruit, which is of no eſtimation. This grows naturally in moſt of the iſlands in the Weſt-Indies, but in much greater plenty at Campeachy, where it abounds greatly. This wood is one of the commodities exported from Jamaica, where it grows in greater plenty than in any other of the Britiſh iſlands.

This tree in the countries where it grows naturally, riſes to the height of ſixty feet or upward; it has a light brown bark, which hath ſome ſhallow furrows; the wood is firm, ſolid, and of a bright yellow colour. It ſends out many branches on every ſide, covered with a white bark, and are garniſhed with leaves about four inches long, which are broad at their baſe, indented at the foot-ſtalk, where they are rounded, but one ſide is broader than the other, ſo that they are oblique to the foot-ſtalk; theſe diminiſh gradually, and end in acute points; they are rough like thoſe of the common Mulberry, of a dark green, and ſtand upon ſhort foot-ſtalks. Toward the end of the young branches come out ſhort katkins of a pale herbaceous colour, and in other parts of the ſame branches the fruit is produced, growing upon ſhort foot-ſtalks; they are as large as nutmegs, of a roundiſh form, full of protuberances like the common Mulberry, green within, and alſo on the outſide, of a luſcious ſweet taſte when ripe.

It is too tender to thrive in this country, unleſs preſerved in a warm ſtove. There are ſeveral of the plants now growing in the Chelſea garden, which were raiſed from ſeeds ſent from Jamaica, by William Williams, Eſq; with many other curious ſorts, which are natives of that iſland. The ſeeds of this plant come up freely on a hot-bed, and when the plants are fit to remove, they ſhould be each planted in a ſeparate ſmall pot filled with freſh light earth, and plunged into a hot-bed of tanners bark, and ſhaded from the ſun till they have taken new root; then they ſhould be treated in the ſame way as other plants from thoſe hot countries, always keeping them in the tan-bed in the ſtove, where they will make good progreſs. Theſe plants retain their leaves great part of the year in the ſtove.

The ſixth ſort grows naturally in China and Japan; it alſo grows naturally in South Carolina, from whence I have received the ſeeds; the inhabitants of Japan make paper of the bark; they cultivate the trees for that purpoſe on the hills and mountains, much after the ſame manner as Oſiers are cultivated here, cutting down the young ſhoots in autumn for their bark. There were ſeveral of theſe trees raiſed from ſeeds a few years paſt, in the gardens of his Grace the Duke of Northumberland, who was ſo good as to favour me with one of the plants, which thrives very well in the open air without any ſhelter, as many of the trees and plants of thoſe countries will do, if they grow on the mountains. This plant makes very ſtrong vigorous ſhoots, but ſeems not to be of tall growth, for it ſends out many lateral branches from the root upward. The leaves are large, ſome of them are entire, others are deeply cut into three, and ſome into five lobes, eſpecially while the trees are young, dividing in form of a hand; they are of a dark green, and rough to the touch, but of a pale green, and ſomewhat hairy on their under ſide, falling off on the firſt approach of froſt in autumn, as do thoſe of the common Mulberry. The deſcription which Kæmpfer gives of the fruit is, that they are a little larger than Peas, ſurrounded with long purple hairs, are compoſed of acini, or protuberances, and when ripe, change to a black purple colour, and are full of ſweet juice.

This tree may be propagated by laying down the branches, in the ſame way as is practiſed for the common Mulberry; or it may be multiplied by planting the cuttings, in the ſame manner as before directed for the common ſort.

The ſeventh ſort grows naturally in India, where it becomes a large tree. It hath ſoft, thick, yellowiſh bark, with a milky juice like the Fig, which is aſtringent. The branches come out on every ſide, which are garniſhed with oblong oval leaves, ſtanding upon ſhort foot-ſtalks; both ſides of theſe leaves are equal, but their edges are unequally ſawed; they are rough, of a dark green on their upper ſide, but pale on their under, ſtanding alternately on the branches. The flowers come out in round heads at the foot-ſtalks of the leaves, on each ſide the branches; they are of an herbaceous white colour; the male flowers have four ſtamina; the female flowers are ſucceeded by roundiſh fruit, which are firſt green, afterwards white, and when ripe turn to a dark red colour. I received the ſeeds of this plant from Bombay, which ſucceeded in the Chelſea garden. The plants are too tender to live out of a ſtove in this country; for as I raiſed a good number of the plants, ſo when they had obtained ſtrength, I placed ſome of them in different ſituations, where they were defended from the froſt, but not any of them ſurvived the winter, but thoſe which were in the bark-ſtove, where they are conſtantly kept, and treated in the ſame manner as other tender plants, giving them but little water in winter, with which management the plants thrive, and retain their leaves all the year.

The eighth ſort grows naturally in Jamaica, and alſo in the Bahama Iſlands, from both which places I have received the ſeeds. The wood of this tree is cut, and ſold for the ſame uſes as the fifth, from which this tree has not been well diſtinguiſhed by the botaniſts: this does not grow to ſo great a ſize as the fifth; the branches are ſlenderer, the leaves are narrower, and are rounded at their baſe, ſawed on their edges, and end in acute points. At the foot-ſtalk of each leaf comes out two ſharp thorns, which, in the older branches grow to the length of two inches. The fruit is ſhaped like that of the fifth ſort, but is ſmaller.

MOSCHATELLINA. See Adoxa.

MOSS. See Muscus.

MOTHERWORT. See Cardiaca.

MOULD, or earth, the goodneſs of which may be known by the ſight, ſmell, and touch.

Firſt, by the ſight: thoſe Moulds that are of a bright Cheſtnut, or hazelly colour, are counted the beſt; of this colour are the beſt loams, and alſo the beſt natural earth, and this will be the better yet, if it cuts like butter, and does not ſtick obſtinately, but is ſhort, tolerably light, breaking into ſmall clods, is ſweet, will be tempered without cruſting or chapping, in dry weather, or turning to mortar in wet.

The next to that, the dark gray and ruſſet Moulds are accounted the beſt, the light and dark Aſh-colour are reckoned the worſt, ſuch as are uſually found on common, or heathy ground; the clear tawny is by no means to be approved, but that of a yellowiſh red colour is accounted the worſt of all; this is commonly found in wild and waſte parts of the country, and for the moſt part produce nothing but Furz and Fern, according as their bottoms are more or leſs of a light and ſandy, or of a ſpewy gravel, or clayey nature.

Secondly, by the ſmell: all lands that are good and wholeſome, will, after rain, or breaking up by the ſpade, emit a good ſmell.

Thirdly, by the touch: by this means we may diſcover whether it conſiſts of ſubſtances entirely arenaceous, or clammy; or, according as it is expreſſed by

Mr. Evelyn, whether it be tender, fatty, deterſive, or ſlippery, or more harſh, gritty, porous, or friable.

That being always the beſt that is between the two extremes, and does not contain the two different qualities of ſoft and hard mixed, of moiſt and dry, of churliſh and mild, that is neither too unctuous or too lean, but ſuch as will diſſolve, of a juſt conſiſtence, between ſand and clay, and ſuch as will not ſtick to the ſpade or fingers upon every flaſh of rain.

A loam, or brick Mould, is not to be diſapproved, as requiring little help or improvement but the ſpade, and is eſteemed both by the gardener and floriſt.

MUCILAGE is a viſcous clammy ſubſtance about ſeeds, &c.

MUCILAGINOUS ſignifies, endowed with a clammy viſcous matter.

MULBERRY. See Morus.

MULLEIN. See Verbascum.

MULTISILIQUOUS plants are ſuch as have after each flower, many diſtinct, long, ſlender, and, oftentimes, crooked caſes, or ſiliquæ, in which their ſeed is contained, and, which, when they ripen, open of themſelves, and let the ſeeds drop. Of this kind is the Bear's-foot, Columbines, common Houſeleek, Navelwort, Orpine, &c.

MUMMY, a ſort of grafting wax, made of one pound of common black pitch, and a quarter of a pound of common turpentine, put into an earthen pot, and ſet on the fire in the open air; in doing this you ought to hold a cover in your hand, ready to cover it, in order to quench it, by putting it thereon, which is to be done ſeveral times, ſetting it on the fire again, that the nitrous and volatile parts may be evaporated. The way to know when it is enough, is by pouring a little of it on a pewter plate, and if it be ſo, it will coagulate preſently; then this melted pitch is to be poured into another pot, and a little common wax is to be added to it, mixing them well together, and then to be kept for uſe.

Dr. Agricola directs the uſing this Mummy as follows:

When you would dreſs roots with this wax, you muſt melt it, and afterwards let it cool a little; then dip in the ends of the roots you would plant (for he propoſes it for the planting pieces of roots of trees, &c.) one after the other, but not too deep, and afterwards to put them in water, and to plant them in the earth, the ſmall end downwards, ſo that the larger end may appear a little way out thereof, and have the benefit of the air, and then to preſs the earth very hard down about them, that they may not receive too much wet, becauſe that would rot them.

Mummy for exotic plants; the ſame author directs the making it as follows:

Take half a pound of gum copal, beat it very fine, and ſearce it; take three pounds of Venice turpentine and melt it over a ſlow fire in a ſtrong earthen pot; when the turpentine is melted and liquidated, put the ſifted gum into it, keep it continually ſtirring with a little ſtick, augmenting the fire gradually, and it will all diſſolve inſenſibly; afterwards let the turpentine evaporate well, and it will thicken; and when it is become of a ſufficient conſiſtence, you may make it up into little rolls, like ſealing-wax, and keep it for uſe.

This Mummy, he ſays, is an excellent vulnerary for plants, it being ſubject to no corruption, as other gummy things are; it hinders any rottenneſs between the ſtock and the root, by means of which the callus is formed the ſooner, and ſpreads over all the parts, and the ſtock becomes entirely connected with the root. It alſo gives ſtrength and vigour to the root, and likewiſe facilitates it.

Vegetable Mummy; the ſame author directs the making of this as follows:

Fill a large kettle, or earthen pot, about a third part full of common black pitch, and add to it a little fine reſin, or ſulphurated pitch, and a little yellow wax; melt theſe together till they become liquid, then take them off the fire, and let them ſtand till they have done ſmoking, and, when cool, you may, with a bruſh, plaſter the inciſions which are made for the inoculation, grafting, &c.

Garden or Foreſt Mummy; the ſame author directs the making it as follows:

Take three pounds of common turpentine, and four pounds of common pitch; melt the turpentine over the fire, and, having beaten the pitch to a powder, throw it in; when they are well mixed together, and grown pretty thick, take it off, and keep it for uſe.

This compoſition may be either made up into little ſticks, like thoſe of ſealing-wax, to be made uſe of on little trees, or it may be kept in little pots, and melted over a ſlow fire, when there is occaſion to uſe it, and, dipping a little bruſh in it, you may plaſter the graft.

The Noble Mummy, or grafting wax; to make this the ſame author directs:

Take two pounds of pure pitch, ſuch as is called at Ratiſbon virgin pitch, and add to it half a pound of good turpentine; put them together in an earthen pot, and ſet them over the fire, that the volatile part of the turpentine may evaporate, otherwiſe it would be very prejudicial to trees and roots. Prove it as you did the former, to know when it is enough; then add to it half a pound of virgin wax, and half an ounce of pounded Myrrh and Aloes; when theſe are well mixed, make it up into little rolls or plaſters, or elſe it may be kept in gallipots.

The time he directs when the operation of the roots is to be performed, is in the month of September, October, and November; though it may ſucceed well at any time of the year, yet thoſe months are the moſt proper ſeaſons for it. The only difference he ſays, is, what is planted in the ſpring, will ſhoot out in June or July, and what is planted in autumn comes not forth till the month of April.

The aforeſaid author mentions great performances by uſing theſe Mummies; thoſe who have a mind to be ſatisfied, may peruſe his treatiſe.

MUNTINGIA. Plum. Gen. Nov. 41. tab. 6. Lin. Gen. Plant. 575.

The Characters are,

The empalement of the flower is cut into five ſegments to the bottom. The flower hath five heart-ſhaped petals, narrow at their baſe, which are inſerted in the empalement, and ſpread open like a Roſe. It has a great number of ſtamina, which are terminated by roundiſh ſummits. In the center is ſituated a roundiſh germen, having no ſtyle, but is crowned by a ſtigma divided into many parts. The germen afterward turns to a ſoft fruit, with one cell, crowned by the ſtigma, like a navel, and filled with ſmall ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's thirteenth claſs, which includes thoſe plants whoſe flowers have many ſtamina and one ſtigma. According to Tournefort's ſyſtem, it muſt be ranged in the eighth ſection of his twenty-firſt claſs, which contains the trees and ſhrubs with a Roſe flower, whoſe empalement becomes a fruit, having hard ſeeds.

We know but one Species of this genus, viz.

Muntingia (*Calabura.*) Jacq. Hiſt. tab. 107. Muntingia folio ſericeo molli, fructu majori. Plum. Nov. Gen. 41. *Muntingia with a ſoft ſilky leaf, and a larger fruit.*

The title of this genus was given to it by Father Plumier, in honour of Dr Muntingius, who was profeſſor of botany at Groningen in Holland, who publiſhed a folio book of botany, entitled, Phytographia Curioſa, in which there are many figures of plants exhibited, engraven on copper-plates; he alſo publiſhed two books of plants in quarto, one of which is entitled, Aloidarum, in which the figures of ſeveral ſorts of Aloes are exhibited; the title of the other is, De Herba Britannica Antiquorum.

This plant is figured and deſcribed by Sir Hans Sloane, in his Hiſtory of Jamaica, by the title of Loti arboris folio anguſtiore, rubi flore, fructu polyſpermo umbilicato, 2. p. 80. This riſes to the height of thirty feet or more in its native ſoil, ſending out many branches toward the top, which are covered with a ſmooth, dark, purple bark, garniſhed with leaves about three inches long, and three quarters broad at their baſe, where they are rounded to a heart-ſhape at the foot-ſtalk, but end in acute points, are very woolly on their under ſide, but ſmooth above, and of a lucid green; they are ſlightly ſawed on their edges, and are placed alternately. The flowers come out from the wings of the ſtalks, ſtanding upon long foot-ſtalks, compoſed of five heart-ſhaped petals, which are white, and ſpread open, reſembling thoſe of the Bramble, having many ſtamina about half the length of the petals, terminated by globular ſummits, and in the center is ſituated a roundiſh germen, crowned by a many-pointed ſtigma. The germen afterward turns to a pulpy umbilicated fruit, as large as the fruit of the Cockſpur Hawthorn, and, when ripe, of a dark purple colour, incloſing many ſmall, hard, angular ſeeds; this ſort has produced flowers and fruit in England.

The ſeeds of this plant were ſent by Mr. Robert Millar from Jamaica, which ſucceeded in ſome of the Engliſh gardens.

The plants are propagated by ſeeds, which ſhould be ſown in pots filled with light rich earth, and plunged into a moderate hot-bed of tanners bark, and in warm weather the glaſſes ſhould be raiſed to admit freſh air. Theſe ſeeds will often remain in the ground a whole year before the plants will appear; in which caſe the pots muſt be kept conſtantly clear from weeds, and ſhould remain in the hot-bed till after Michaelmas, when they may be removed into the ſtove, and plunged into the bark-bed, between other pots of tall plants, where they may remain during the winter ſeaſon. Theſe pots ſhould be now and then watered, when the earth appears dry, and in the beginning of March the pots ſhould be removed out of the ſtove, and placed into a freſh bark-bed under frames, which will bring up the plants ſoon after.

When the plants are come up about two inches high, they ſhould be carefully taken out of the pots, and each planted into a ſeparate ſmall pot filled with light rich earth, and then plunged into the hot-bed again, obſerving to ſhade them from the ſun until they have taken new root, after which time they ſhould be duly watered, and in warm weather they muſt have a large ſhare of freſh air. In this hot-bed the plants may remain until autumn, when the nights begin to be cold; at which time they ſhould be removed into the ſtove, and plunged into the bark-bed. During the winter ſeaſon theſe plants muſt be kept warm, eſpecially while they are young, and frequently refreſhed with water; but it muſt not be given to them in large quantities, leſt it rot the tender fibres of their roots. It will be proper to continue theſe plants in the ſtove all the year, but in warm weather they ſhould have a large ſhare of freſh air; but as the plants grow in ſtrength, they will be more hardy, and may be expoſed in ſummer for two or three months, and in winter will live in a dry ſtove, if kept in a moderate degree of heat.

MURUCUIA. See PASSIFLORA.

MUSA. Plum. Nov. Gen. 24. tab. 34. Lin. Gen. Plant. 1010. The Plantain-tree.

The CHARACTERS are,

It hath male and female flowers upon the ſame foot-ſtalk, ſome of which are hermaphrodite; theſe are produced on a ſingle ſtalk (or ſpadix;) the male flowers are ſituated on the upper part of the ſpike, and the female below; theſe are in bunches, each bunch having a ſheath, or cover, which falls off. The flowers are of the lip kind. The petals conſtitute the upper lip, and the nectarium the under; they have ſix awl-ſhaped ſtamina, five of which are ſituated in the petal, and the ſixth in the nectarium; this is double the length of the other, terminated by a linear ſummit; the others have none. The germen is ſituated under the flower, which is long, having three obtuſe angles, ſupporting an erect cylindrical ſtyle, crowned by a roundiſh ſtigma. The germen afterward turns to an oblong, three-cornered, fleſhy fruit, covered with a thick rind, divided into three parts.

This genus of plants is ranged in the firſt ſection of Linnæus's twenty-third claſs, which includes thoſe plants with male and female flowers, which have hermaphrodite flowers on the ſame ſtalk. Plumier ranges it in Tournefort's claſs, with the anomalous flowers of ſeveral petals; and Garçin places it among the plants with a Lily flower.

The SPECIES are,

1. MUSA (*Paradiſiaca*) ſpadice nutante floribus maſculis perſiſtentibus. Lin. Sp. 1477. *Muſa with a nodding ſpike, and nodding male flowers.* Muſa fructu cucumerino longiorio. Plum. Nov. Gen. 24. *Muſa with a longer Cucumber-ſhaped fruit, commonly called Plantain-tree.*
2. MUSA (*Sapientum*) ſpadice nutante floribus maſculis deciduis. Lin. Sp. 1477. *Muſa with a nodding ſpike, and deciduous male flowers.* Muſa fructu cucumerino, breviore. Plum. Nov. Gen. 24. *Muſa with a ſhorter Cucumber-ſhaped fruit, commonly called Bonana.*

The firſt ſort is cultivated in all the iſlands of the Weſt-Indies, where the fruit generally ſerves the negroes for bread, and ſome of the white people alſo prefer it to moſt other ſorts, eſpecially to the Yams, and Caſſada bread.

This plant riſes with a ſoft herbaceous ſtalk fifteen or twenty feet high, and upward; the lower part of the ſtalk is often as large as a man's thigh, diminiſhing gradually to the top, where the leaves come out on every ſide, which are often more than ſix feet long, and near two feet broad, with a ſtrong fleſhy midrib, and a great number of tranſverſe veins running from the midrib to the borders. The leaves are thin and tender, ſo that where they are expoſed to the open air, they are generally torn by the wind; for as they are large, the wind has great power againſt them: theſe leaves come out from the ſide of the principal ſtalk, incloſing it with their baſe; they are rolled up at their firſt appearance, but when they are advanced above the ſtalk, they expand quite flat, and turn backward; as theſe leaves come up rolled in the manner before mentioned, their advance upward is ſo quick, that their growth may be almoſt diſcerned by the naked eye; and if a line is drawn acroſs, level with the top of the leaf, in an hour's time the leaf will be near an inch above it. When the plant is grown to its full height, the ſpike of flowers will appear from the center of the leaves, which is often near four feet in length, and nods on one ſide. The flowers come out in bunches, thoſe on the lower part of the ſpike being the largeſt; the others diminiſh in their ſize upward; each of theſe bunches is covered with a ſpathæ or ſheath, of a fine purple colour within, which drops off when the flowers open. The upper part of the ſpike is made up of male or barren flowers, which are not ſucceeded by fruit, but thoſe of the ſecond ſort fall off with their covers. The fruit of this is eight or nine inches long, and above an inch diameter, a little incurved, and has three angles; it is at firſt green, but, when ripe, of a pale yellow colour. The ſkin is tough, and within is a ſoft pulp of a luſcious ſweet flavour. The ſpikes of fruit are often ſo large as to weigh upwards of forty pounds.

The fruit of the firſt ſort is generally cut before it is ripe, and roaſted in the embers, then it is eaten inſtead of bread. The leaves are uſed for napkins and table cloths, and are food for hogs.

The ſecond ſort, which is commonly called Bonana, differs from the firſt, in having its ſtalks marked with dark purple ſtripes and ſpots. The fruit is ſhorter, ſtraiter, and rounder, and the male flowers drop off; the pulp is ſofter, and of a more luſcious taſte, ſo is generally eaten by way of deſert, and ſeldom uſed in the ſame way as the Plantain, therefore is not cultivated in ſuch plenty.

Both theſe plants were carried to the Weſt-Indies from the Canary Iſlands, to which place it is believed they were carried from Guinea, where they grow naturally: theſe plants are alſo cultivated in Egypt, and in moſt other hot countries, where they grow to perfection in about ten months, from their firſt planting, to the ripening of their fruit; when their ſtalks are cut down, ſeveral ſuckers come up from the root; they will alſo produce fruit in ten months after, ſo that by cutting down the ſtalks at different times, there is a conſtant ſucceſſion of fruit all the year.

In Europe there are ſome of theſe plants preſerved in the gardens of curious perſons, who have hot-houſes capacious enough for their reception, in many of which they have ripened their fruit very well; but as they grow very tall and their leaves are large, they require more room in the ſtove than moſt people care to allow them: they are propagated by ſuckers, which come from the roots of thoſe plants which have fruited; and many times the younger plants, when they are ſtinted in growth, will put out ſuckers; theſe ſhould be carefully taken off, preſerving ſome fibres to their roots, and planted in pots filled with light rich earth, and plunged into the tan-bed in the ſtove: theſe may be taken off any time in ſummer, and it is beſt to take them off when young, becauſe if their roots are grown large, they do not put out new fibres ſo ſoon, and when the thick part of the root is cut in taking off, the plants often rot.

During the ſummer ſeaſon theſe plants muſt be plentifully watered, for the ſurface of their leaves being large, there is a great conſumption of moiſture, by perſpiration in hot weather, but in the winter they muſt be watered more ſparingly; though at that ſeaſon they muſt be often refreſhed, but it muſt not be given them in ſuch quantities.

The pots in which theſe plants are placed, ſhould be large in proportion to the ſize of the plants, for their roots generally extend pretty far, and the earth ſhould be rich and light. The degree of heat with which theſe plants thrive beſt, is much the ſame with the Anana, or Pine Apple, in which I have had many of theſe plants produce their fruit in perfection, and they were near twenty feet high.

The moſt ſure method to have theſe plants fruit in England is, after they have grown for ſome time in pots, ſo as to have made good roots, to ſhake them out of the pots with the ball of earth to their roots, and plant them into the tan-bed in the ſtove, obſerving to lay a little old tan near their roots for their fibres to ſtrike into, and in a few months the roots of theſe plants will extend themſelves many feet each way in the bark; and theſe plants will thrive a great deal faſter than thoſe which are confined in pots, or tubs. When the bark-bed wants to be renewed with freſh tan, there ſhould be great care taken of the roots of theſe plants, not to cut or break them, as alſo to leave a large quantity of the old tan about them, becauſe if the new tan is laid too near them, it will ſcorch their roots, and injure them: theſe plants muſt be plentifully ſupplied with water, otherwiſe they will not thrive; in winter they ſhould be watered twice a week, giving at leaſt two quarts to each plant, but in ſummer they muſt be watered every other day, and double the quantity given to them each time. If the plants puſh out their flower-ſtems in the ſpring, there will be hopes of their perfecting their fruit; but when they come out late in the year, the plants will ſometimes decay before the fruit is ripe. The ſtoves in which theſe plants are placed ſhould be at leaſt twenty feet in height, otherwiſe there will not be room for their leaves to expand; for when the plants are in vigour, the leaves are often eight feet in length, and two feet broad: ſo that if the ſtems grow to be fourteen feet to the diviſion of the leaves, and the houſe is not twenty feet high, the leaves will be cramped, which will retard the growth of the plants; beſides, when the leaves are bent againſt the glaſs, there will be danger of their breaking them, when they are growing vigorouſly; for I have had in one night the ſtems of ſuch bent leaves force through the glaſs, and by the next morning advanced two or three inches above the glaſs.

I have ſeen ſome bunches of fruit of the firſt ſort, which were upwards of forty pounds weight, and perfectly ripe in England; but this is not ſo good a fruit, as to tempt any perſon to be at the expence of raiſing them in England. The ſecond ſort is preferred to the firſt, for the flavour of its fruit, in all thoſe hot countries where theſe plants abound: the bunches of theſe are not near ſo large as thoſe of the firſt ſort, nor are the ſingle fruit near ſo long; theſe change to a deeper yellow colour as they ripen, but their taſte is ſomewhat like that of meally Figs. Some perſons who have reſided in the Weſt-Indies, having eaten ſome of theſe fruit which were produced in England, and thought them little inferior to thoſe which grew in America; and I imagine, that the inhabitants of thoſe countries would not eſteem theſe fruits ſo much, had they variety of other ſorts; but, for want of better, they eat many kinds of fruit, which would not be valued in Europe, could they be obtained in perfection.

MUSCARI. Tourn. Inſt. R. H. 347. tab. 180. Muſk, or Grape Hyacinth, vulgò.

The CHARACTERS are,

The flower has no empalement. It hath one oval pitcher-ſhaped petal, which is reflexed at the brim. It hath three nectariums on the top of the germen, and ſix awl-ſhaped ſtamina which are ſhorter than the petal, whoſe ſummits join together, and in the center is ſituated a roundiſh three-cornered germen, ſupporting a ſingle ſtyle, crowned by an obtuſe ſtigma. The germen afterward turns to a roundiſh three-cornered capſule, having three cells, filled with roundiſh ſeeds.

Dr. Linnæus has joined this genus to the Hyacinth, which is placed in the firſt ſection of his ſixth claſs, which contains the plants whoſe flowers have ſix ſtamina and one ſtyle.

The SPECIES are,

1. MUSCARI (*Botryoide*) corollis globoſis uniformibus, foliis canaliculato-cylindricis ſtrictis. *Muſcari with uniform globular petals, and cylindrical gutter-ſhaped leaves.* Muſcari arvenſe, juncifolium, cæruleum, minus. Tourn. Inſt. 348. *Smaller blue Field Muſcary, with Ruſh leaves, commonly called Grape Hyacinth.*
2. MUSCARI (*Comoſus*) corollis angulato-cylindricis, ſummis ſterilibus longiùs pedicellatis. *Muſcari with angular cylindrical petals, which on the top of the ſpike are barren, and have longer foot-ſtalks.* Muſcari arvenſe, latifolium, purpuraſcens. Tourn. Inſt. 347. *Broad-leaved, purple, Field Muſcari, commonly called Fair-haired Hyacinth.*
3. MUSCARI (*Racemoſus*) corollis ovatis, ſummis ſeſſilibus foliis laxis. *Muſcari with oval petals.* Muſcari obſoletiore flore. Cluſ. Hiſt. 1. p. 178. *Muſcari with an obſolete flower, commonly called Muſk Hyacinth.*
4. MUSCARI (*Monſtroſus*) corollis ſubovatis. *Muſcari with almoſt oval corolla.* Hyacinthus paniculâ cæruleâ. C. B. P. 42. *Blue paniculated Hyacinth, called Feathered Hyacinth.*
5. MUSCARI (*Orchioide*) corollis ſexpartitis, petalis tribus exterioribus brevioribus. *Muſcari with petals which are cut into ſix parts.* Hyacinthus orchioides Africanus major bifolius maculatus, flore ſulphureo, obſoleto majore. Breyn. Prod. 3. 24. *Greater African Hyacinth, reſembling Orchis, with two ſpotted leaves, and a larger, obſolete, ſulphur-coloured flower.*

The firſt ſort grows naturally in the vineyards and arable fields in France, Italy, and Germany, and where it is once planted in a garden, it is not eaſily rooted out, for the roots multiply greatly, and if they are permitted to ſcatter their ſeeds, the ground will be filled with the roots. There are three varieties of this, one with blue, another with white, and a third with Aſh-coloured flowers: the firſt ſort hath a ſmall, round, bulbous root, from which come out many leaves about ſix inches long, which are narrow, and their edges are incurved, ſo as to be ſhaped like a gutter: between theſe ariſe the flower-ſtalk, which is naked, and toward the top garniſhed with a cloſe ſpike of blue flowers, ſhaped like pitchers, ſitting very cloſe to the ſtalk; theſe ſmell like freſh ſtarch, or the ſtones of Plumbs which are freſh. They flower in April, and the ſeeds ripen the latter end of June.

The ſecond ſort grows naturally in Spain and Portugal, from whence I have received both roots and ſeeds; this hath a bulbous root as large as a middling Onion, from which come out five or ſix leaves a foot long, and three quarters of an inch broad at their baſe, diminiſhing gradually to a point. The flower-ſtalk riſes about a foot high, the lower half naked, but the upper is garniſhed with cylindrical, angular, purple flowers, ſtanding upon foot-ſtalks half an inch long; theſe grow horizontally, but the ſtalk is terminated by a tuft of flowers whoſe petals are oval, and have neither germen or ſtyle, ſo are barren. This ſort flowers the latter end of April, or the beginning of May; there is a variety of this with white, and another with blue flowers, but the purple is the moſt common.

The third ſort hath pretty large, oval, bulbous roots, from which ariſe ſeveral leaves, which are about eight or nine inches long, and half an inch broad; they are incurved a little on their ſides, and end in obtuſe points; theſe embrace each other at their baſe; out of the middle of theſe, the ſtalk which ſuſtains the flowers ariſes; they are naked below, but their upper parts are garniſhed with ſmall flowers growing in a ſpike; theſe have oval pitcher-ſhaped petals, which are reflexed at their brim, and are of an Aſh-coloured purple, or obſolete colour, ſeeming as if faded, but have an agreeable muſky ſcent: theſe ſtalks do not riſe more than ſix inches high, ſo the flowers make no great appearance; but where they are in ſome quantity, they will perfume the air to a conſiderable diſtance. This ſort flowers in April, and the ſeeds ripen in July.

Of this there are two varieties, one of which has the ſame coloured flowers with this here enumerated, on the lower part of the ſpike, but they are larger, and have more of the purple caſt, but the flowers on the upper part of the ſpike are yellow, and have a very grateful odour. The Dutch gardeners title it Tibcadi Muſcari. As this is ſuppoſed to be only a ſeminal variety of the third, I have not enumerated it as diſtinct. There is another variety of this with very large yellow flowers, that has been lately raiſed from ſeeds in Holland, which the floriſts there ſell for a guinea a root.

The fourth ſort hath a large bulbous root, from which come out ſeveral plain leaves a foot long, and about half an inch broad at their baſe; they are ſmooth, and end in obtuſe points. The flower-ſtalks riſe near a foot and a half high; they are naked at the bottom for about ſeven or eight inches, above which the panicles of flowers begin, and terminate the ſtalks. The flowers ſtand upon foot-ſtalks which are more than an inch long, each ſuſtaining three, four, or five flowers, whoſe petals are cut into ſlender filaments like hairs; they are of a purpliſh blue colour, and have neither ſtamina or germen, ſo do never produce ſeeds. It flowers in May, and, after the flowers are paſt, the ſtalks and leaves decay to the root, and new ones ariſe the following ſpring.

The fifth ſort grows naturally at the Cape of Good Hope, from whence I received the ſeeds, which ſucceeded in the Chelſea garden, where the plants have flowered for ſeveral years paſt; this hath a ſmall, white, bulbous root, about the ſize of a Hazel nut, from which comes out generally but two, (though ſometimes when the roots are ſtrong) three leaves, which are five or ſix inches long, and one inch and a half broad in the middle, ending in obtuſe points; theſe are of a lucid green, and have many ſpots, or protuberances on their upper ſurface. The flower-ſtalk riſes between them to the height of ſix or ſeven inches; it is round, ſmooth, and naked for three inches high or more, and is terminated by a ſpike of flowers, which are of a pale ſulphur colour; theſe have no foot-ſtalks; they have one petal, which is of an irregular figure, and cut at the top into ſix parts. The ſtamina are almoſt equal with the petal, and ſtand round the ſtyle, which is of the ſame length. The flowers appear in March, but are ſeldom ſucceeded by good ſeeds here.

The four firſt ſorts are very hardy, ſo will thrive in the open air, and require no other culture than any other hardy bulbous-rooted flower; which is, to take up their roots every ſecond or third year to ſeparate their bulbs, for as ſome of the ſorts multiply pretty faſt, ſo when they are become large bunches, they do not flower ſo ſtrong as when they are ſingle: the beſt time to take them out of the ground, is ſoon after their ſtalks and leaves are decayed; then they ſhould be ſpread on a mat, in a dry ſhady room for a fortnight to dry, after which they may be kept in boxes like other bulbous roots, till Michaelmas, when they may be planted again in the borders of the flower-garden, and treated in the ſame way as the common hardy kinds of Hyacinths.

The firſt ſort ſhould not be admitted into the flower-garden, becauſe the roots will propagate ſo faſt, as to become a troubleſome weed there.

The ſecond ſort has but little beauty, ſo a few of theſe only ſhould be allowed a place merely for the ſake of variety; this is ſo hardy, as to thrive in any ſoil or ſituation.

The third ſort merits a place for the extreme ſweetneſs of its flowers, but eſpecially that variety of it with yellow flowers, called Tibcady.

The fourth ſort may alſo be allowed to have place in the common borders of the pleaſure-garden, where they will add to the variety, and are by no means to be deſpiſed.

They are all eaſily propagated by offsets, which moſt of their roots ſend out in pretty great plenty, ſo that there is little occaſion for ſowing of their ſeeds, unleſs it be to gain ſome new varieties.

The fifth ſort is too tender to thrive in the open air in England, ſo the roots muſt be planted in ſmall pots, filled with light rich earth; and in the autumn they ſhould be placed under a hot bed-frame, where they may be protected from froſt, but ſhould have as much free air as poſſible in mild weather; for when theſe are placed in a green-houſe, their leaves are drawn long and narrow, and the flower-ſtalks are generally weak, ſo never flower ſo well as when they have plenty of free air. Theſe flowers will continue a month where they are not drawn, but will decay in half that time in a green-houſe.

Theſe roots ſhould be tranſplanted in July, when their ſtalks and leaves are decayed, and ſhould be placed in the open air during the ſummer ſeaſon, but ſhould have very little water when their leaves are decayed.

MUSCIPULA. See Silene.

MUSCOSE, MUSCOSUS, Moſſy, or abounding with Moſs.

MUSCOSITY, Moſſineſs.

MUSCUS, Moſs.

Theſe, though formerly ſuppoſed to be only excreſcences produced from the earth, trees, &c. yet are no leſs perfect plants than thoſe of greater magnitude, having roots, branches, flowers, and ſeeds, but yet cannot be propagated from the latter by any art.

The botaniſts diſtinguiſh theſe into ſeveral genera, under each of which are ſeveral ſpecies; but as they are plants of no uſe or beauty, it would be to little purpoſe to enumerate them in this place.

Theſe plants chiefly flouriſh in cold countries, and in the winter ſeaſon, and are many times very injurious to fruit-trees, which grow upon cold barren ſoils, or where they are ſo cloſe planted as to exclude the free acceſs of air. The only remedy in ſuch caſes is to cut down part of the trees, and plough up the ground between thoſe left remaining: and in the ſpring of the year, in moiſt weather, you ſhould, with an iron inſtrument made a little hollow, the better to ſurround the branches of the trees, ſcrape off the Moſs, carrying it off the place; and by two or three times thus cleanſing them, together with carefully ſtirring the ground, it may be entirely deſtroyed from the trees; but if you do not cut down part of the trees, and ſtir the ground well, the rubbing off the Moſs will ſignify little; for the cauſe not being removed, the effect will not ceaſe, but the Moſs will in a ſhort time be as troubleſome as ever.

MUSHROOMS are, by many perſons, ſuppoſed to be produced from the putrefaction of the dung, earth, &c. in which they are found; but notwithſtanding this notion is pretty generally received amongſt the unthinking part of mankind, yet by the curious naturaliſts, they are eſteemed perfect plants, though their flowers and ſeeds have not as yet been perfectly diſcovered. But ſince they may, and are annually propagated by the gardeners near London, and are (the eſculent ſort of them) greatly eſteemed by moſt curious palates, I ſhall briefly ſet down the method practiſed by the gardeners who cultivate them for ſale.

But firſt, it will not be improper to give a ſhort deſcription of the true eatable kind, ſince there are ſeveral unwholſome ſorts, which have been by unſkilful perſons gathered for the table.

The true Champignon, or Muſhroom, appears at firſt of a roundiſh form, like a button; the upper part of which, as alſo the ſtalk, is very white; but being opened, the under part is of a livid fleſh colour, but the fleſhy part when broken is very white; when theſe are ſuffered to remain undiſturbed, they will grow to a large ſize, and explicate themſelves almoſt to a flatneſs, and the red part underneath will change to a dark colour.

In order to cultivate them, if you have no beds in your own, or in neighbouring gardens, which produce them, you ſhould look abroad in rich paſtures, during the months of Auguſt and September, until you find them (that being the ſeaſon when they are naturally produced;) then you ſhould open the ground about the roots of the Muſhrooms, where you will find the earth, very often, full of ſmall white knobs, which are the offſets, or young Muſhrooms; theſe ſhould be carefully gathered, preſerving them in lumps with the earth about them: but as this ſpawn cannot be found in the paſture, except at the ſeaſon when the Muſhrooms are naturally produced, you may probably find ſome in old dunghills, eſpecially where there has been much litter amongſt it, and the wet hath not penetrated it to rot it; as likewiſe, by ſearching old hot-beds, it may be often found; for this ſpawn has the appearance of a white mould, ſhooting out in long ſtrings, by which it may be eaſily known wherever it is met with: or this may be procured by mixing ſome long dung from the ſtable, which has not been thrown on a heap to ferment; which being mixed with ſtrong earth, and put under cover to prevent wet getting to it, the more the air is excluded from it, the ſooner the ſpawn will appear; but this muſt not be laid ſo cloſe together as to heat, for that will deſtroy the ſpawn: in about two months after the ſpawn will appear, eſpecially if the heap is cloſely covered with old thatch, or ſuch litter as hath lain long abroad, ſo as not to ferment, then the beds may be prepared to receive the ſpawn: theſe beds ſhould be made of dung, in which there is good ſtore of litter, but this ſhould not be thrown on a heap to ferment; that dung which hath lain ſpread abroad for a month or longer, is beſt. Theſe beds ſhould be made on dry ground, and the dung laid upon the ſurface; the width of theſe beds at bottom ſhould be about two feet and a half or three feet, the length in proportion to the quantity of Muſhrooms deſired; then lay the dung about a foot thick, covering it about four inches with ſtrong earth. Upon this lay more dung, about ten inches thick; then another layer of earth, ſtill drawing in the ſides of the bed, ſo as to form it like the ridge of a houſe, which may be done by three layers of dung and as many of earth. When the bed is finiſhed it ſhould be covered with litter or old thatch, to keep out wet, as alſo to prevent its drying; in this ſituation it may remain eight or ten days, by which time the bed will be in a proper temperature of warmth to receive the ſpawn; for there ſhould be only a moderate warmth in it, great heat deſtroying the ſpawn, as will alſo wet; therefore when the ſpawn is found, it ſhould always be kept dry until it is uſed, for the drier it is, the better it will take in the bed; for I had a parcel of this ſpawn, which had lain near the oven of a ſtove upward of four months, and was become ſo dry, that I deſpaired of its ſucceſs; but I never have yet ſeen any which produced ſo ſoon, nor in ſo great quantity as this.

The bed being in a proper temperature for the ſpawn, the covering of litter ſhould be taken off, and the ſides of the bed ſmoothed; then a covering of light rich earth about an inch thick ſhould be laid all over the bed, but this ſhould not be wet; upon this the ſpawn ſhould be thruſt, laying the lumps four or five inches aſunder; then gently cover this with the ſame light earth above half an inch thick, and put the covering of litter over the bed, laying it ſo thick as to keep out wet, and prevent the bed from drying: when theſe beds are made in the ſpring or autumn, as the weather is in thoſe ſeaſons temperate, ſo the ſpawn will then take much ſooner, and the Muſhrooms will appear perhaps in a month after making; but thoſe beds which are made in ſummer, when the ſeaſon is hot, or in winter, when the weather is cold, are much longer before they produce.

The great ſkill in managing of theſe beds is, that of keeping them in a proper temperature of moiſture, never ſuffering them to receive too much wet: during the ſummer ſeaſon the beds may be uncovered, to receive gentle ſhowers of rain at proper times; and in long dry ſeaſons the beds ſhould be now and then gently watered, but by no means ſuffer much wet to come to them; during the winter ſeaſon they muſt be kept as dry as poſſible, and ſo cloſely covered as to keep out cold. In froſty or very cold weather, if ſome warm litter ſhaken out of a dung heap is laid on, it will promote the growth of the Muſhrooms; but this muſt not be laid next the bed, but a covering of dry litter between the bed and this warm litter; and as often as the litter is found to decay, it ſhould be renewed with freſh; and as the cold increaſes, the covering ſhould be laid ſo much thicker. If theſe things are obſerved, there may be plenty of Muſhrooms produced all the year; and theſe produced in beds, are much better for the table than any of thoſe which are gathered in the fields.

A bed thus managed, if the ſpawn takes kindly, will continue good for ſeveral months, and produce great quantities of Muſhrooms; from theſe beds when they are deſtroyed, you ſhould take the ſpawn for a freſh ſupply, which may be laid up in a dry place until the proper ſeaſon of uſing it, which ſhould not be ſooner than five or ſix weeks, that the ſpawn may have time to dry before it is put into the bed, otherwiſe it will not ſucceed well.

Sometimes it happens, that beds thus made do not produce any Muſhrooms till they have lain five or ſix months, ſo that theſe beds ſhould not be deſtroyed, though they ſhould not at firſt anſwer expectation; for I have frequently known theſe to have produced great quantities of Muſhrooms afterward, and have continued a long time in perfection.

MUSTARD. See Sinapi.

MYAGRUM. Tourn. Inſt. R. H. 211. tab. 99. Lin. Gen. Plant. 713. Gold of Pleaſure.

The Characters are,

The empalement of the flower is compoſed of four oblong, oval, coloured leaves, which fall off. The flower hath four roundiſh obtuſe petals, placed in form of a croſs. It hath ſix ſtamina the length of the petals, four of which are a little longer than the other, terminated by ſingle ſum-

mits. In the center is ſituated an oval germen, ſupporting ſlender ſtyle, crowned by an obtuſe ſtigma. The germen afterward becomes a turbinated, heart-ſhaped, ſhort pod, having two valves with a rigid ſtyle on the top, incloſing roundiſh ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's fifteenth claſs, which contains the plants whoſe flowers have four long and two ſhorter ſtamina, and the ſeeds are incloſed in ſhort ſmall pods.

The Species are,

1. Myagrum (*Sativum*) ſiliculis ovatis, pedunculatis polyſpermis. Hort. Cliff. 328. *Myagrum with oval pods having foot-ſtalks, incloſing ſeveral ſeeds.* Alyſſon ſegetum foliis auriculatis acutis. Tourn. Inſt. R. H. *Corn Madwort with eared acute-pointed leaves, commonly called Gold of Pleaſure.*
2. Myagrum (*Alyſſum*) ſiliculis cordatis pedunculatis polyſpermis, foliis denticulatis obtuſis. *Myagrum with heart-ſhaped pods ſtanding upon foot-ſtalks, having many ſeeds and indented leaves.* Alyſſon ſegetum foliis auriculatis acutis fructu majori. Tourn. Inſt. 217. *Corn Madwort, with acute-eared leaves and a larger fruit.*
3. Myagrum (*Rugoſum*) ſiliculis globoſis compreſſis punctato-rugoſis. Hort. Cliff. 328. *Myagrum with globular, compreſſed, ſmall pods, having rough punctures.* Rapiſtrum arvenſe, folio auriculato acuto. Tourn. Inſt. 211. *Field Charlock with an acute-eared leaf.*
4. Myagrum (*Perenne*) ſiliculis biarticulatis diſpermis, foliis extrorſum ſinuatis denticulatis. Hort. Upſal. 182. *Myagrum with ſhort pods, having two joints and two ſeeds, and outer leaves which are ſinuated and indented.* Rapiſtrum monoſpermum. C. B. P. 95. *One-ſeeded Charlock.*
5. Myagrum (*Perfoliatum*) ſiliculis obcordatis ſubſeſſilibus, foliis amplexicaulibus. Hort. Upſal. 182. *Myagrum with ſmall heart-ſhaped pods ſitting cloſe to the ſtalk, and the leaves embracing it.* Myagrum monoſpermum latifolium. C. B. P. 109. *Broad-leaved Myagrum having one ſeed in a pod.*

The firſt ſort grows naturally in Corn fields in the ſouth of France and Italy; I have alſo found it growing in the Corn in Eaſthamſted-park, the ſeat of William Trumbull, Eſq; but it is not common in this country. It is an annual plant, with an upright ſtalk about a foot and a half high, ſending out two or four ſide branches toward the top, which grow erect; they are ſmooth, and have a fungous pith; the lower leaves are from three to four inches long, of a pale or yellowiſh green, and are eared at their baſe; thoſe upon the ſtalks diminiſh in their ſize all the way up, and are entire, and almoſt embrace the ſtalks with their baſe. The flowers grow in looſe ſpikes at the end of the branches, ſtanding upon foot-ſtalks an inch long; they are compoſed of four ſmall yellowiſh petals, placed in form of a croſs; theſe are ſucceeded by oval capſules, which are bordered, and crowned at the top with the ſtyle of the flower, having two cells, which are filled with red ſeeds.

The ſecond ſort is alſo an annual plant, and differs from the firſt in having a taller ſtalk; the leaves are much longer, narrower, and are regularly indented on their edges, ending in obtuſe points. The flowers are larger, but of the ſame form and colour; the capſules are much larger, and are ſhaped like a heart. Both theſe plants flower in June and July, and their ſeeds ripen in September.

The third ſort grows naturally on the borders of arable fields, in the ſouth of France and Italy. This is an annual plant, whoſe lower leaves are five or ſix inches long; they are hairy and ſucculent; their baſe is eared, and they end in acute points. The ſtalks riſe a foot and a half high, they are brittle and hairy, branching out toward the top like the two former, and are terminated by ſhort looſe ſpikes of ſmall pale flowers, which are ſucceeded by ſmall, rough, roundiſh capſules, compreſſed at the top. It flowers in July, and the ſeeds ripen in autumn.

The fourth ſort grows naturally amongſt the Corn, in France and Germany. This is alſo an annual plant; the lower leaves are large, jagged, and hairy; the ſtalks branch out from the bottom, and are garniſhed with leaves about four inches long and two broad; they are hairy, and unequally jagged. The ſtalks are terminated by very long looſe ſpikes of yellow flowers, which are ſucceeded by ſhort pods with two joints, each including one roundiſh ſeed. It flowers about the ſame time with the former.

The fifth ſort grows naturally in the ſouth of France and Italy; this hath a ſmooth branching ſtalk upward of two feet high; the lower leaves are five or ſix inches long, ſmooth, ſucculent, and a little indented; the upper leaves almoſt embrace the ſtalks with their baſe. The flowers are produced in long looſe ſpikes, which are yellow, and ſit cloſe to the ſtalk; theſe are ſucceeded by heart-ſhaped compreſſed pods, divided into two cells by a longitudinal partition, each containing one roundiſh ſeed. It flowers at the ſame time with the former.

If the ſeeds of all theſe are permitted to ſcatter in the autumn, the plants will riſe without any care, and only require to be thinned and kept clean from weeds. Theſe autumnal plants will always ripen their ſeeds, whereas thoſe which are ſown in the ſpring ſometimes fail.

MYOSOTIS. Dill. Gen. 3. Lin. Gen. 180. Mouſe-ear.

The Characters are,

The flower hath an oblong, erect, permanent empalement, cut into five points; the flower is ſalver-ſhaped, having a ſhort cylindrical tube, cut into five obtuſe ſegments at the brim; the chaps are cloſed by five ſmall ſcales which join, and are prominent. It hath five ſhort ſtamina in the neck of the tube, terminated by ſmall ſummits; and four germen ſupporting a ſlender ſtyle the length of the tube, crowned by an obtuſe ſtigma; the germina afterward become four oval ſeeds incloſed in the empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, the flower having five ſtamina and one ſtyle.

The Species are,

1. Myosotis (*Virginica*) ſeminibus aculeatis glochidibus, foliis ovato-oblongis, ramis divaricatis. Lin. Sp. 189. *Mouſe-ear with prickly ſeeds, oblong oval leaves, and divaricated branches.* Cynogloſſum Virginianum, flore & fructu minimo. Mor. Hiſt. 3. tab. 30. fol. 9. *Virginian Hound's-tongue, with ſmall flowers and ſeeds.*
2. Myosotis (*Lappula*) ſeminibus aculeis glochidibus, foliis lanceolatis piloſis. Flor. Suec. 150. *Mouſe-ear with prickly ſeeds, and hairy ſpear-ſhaped leaves.* Cynogloſſum minus. C. B. P. 257. *Smaller Hound's-tongue.*
3. Myosotis (*Apula*) ſeminibus nudis, foliis hiſpidis, racemis folioſis. Lin. Sp. 189. *Mouſe-ear with naked ſeeds, ſtinging leaves, and leafy branches.* Echium luteum minimum. C. B. P. 254. *The leaſt yellow Viper's Bugloſs.*

There are one or two other ſpecies of this genus which grow naturally in England, ſo are rarely admitted into gardens, therefore are omitted here: and thoſe here enumerated are ſeldom cultivated except in botanic gardens, being plants of little beauty or uſe. Thoſe perſons who are deſirous of keeping them, ſhould ſow their ſeeds in the autumn, upon an open bed or border of light earth, and in the ſpring thin the plants where they are too cloſe, and keep them clean from weeds, which is all the culture they require; and if their ſeeds are permitted to ſcatter, the plants will riſe without farther trouble.

MYOSURUS, Mouſe-tail.

This plant is very near a-kin to the Ranunculus, in which genus it is ranged by ſome botaniſts; the flowers are extremely ſmall, and are ſucceeded by long ſlender ſpikes of ſeeds, reſembling the tail of a mouſe, from whence it had the name. It grows wild upon moiſt grounds in divers parts of England, where it flowers the latter end of April; and the ſeeds ripen in a month after, when the plants decay, being annual. It is rarely cultivated in gardens, ſo I ſhall not trouble the reader with any further account of it.

MYRICA. Lin. Gen. Plant. 981. Gale. Tourn. Act. Reg. Scien. 1706. The Candleberry Myrtle, Gale, or Sweet Willow; by ſome Myrtus Brabantica, or Dutch Myrtle; in French, *Piment Royal.*

The Characters are,

The male flowers are upon different plants from the female; the male flowers are produced in a looſe, oblong, oval katkin, imbricated on every ſide; under each ſcale is ſituated one moon-ſhaped flower, having no petal, but hath four or ſix ſhort ſlender ſtamina, terminated by large twin ſummits, whoſe lobes are bifid. The female flowers have neither petal or ſtamina, but an oval germen ſupporting two ſlender ſtyles, crowned by ſingle ſtigmas. The germen afterward becomes a berry with one cell, incloſing a ſingle ſeed.

This genus of plants is ranged in the fourth ſection of Linnæus's twenty-ſecond claſs, which includes the plants whoſe male flowers have four ſtamina, and are upon different plants from the fruit.

The Species are,

1. Myrica (*Gale*) foliis lanceolatis ſubſerratis, caule fruticoſo. Lin. Sp. Plant. 1024. *Myrica with ſpear-ſhaped ſawed leaves and a ſhrubby ſtalk.* Gale frutex odoratus ſeptentrionalium. J. B. 1. p. 2. 225. *Northern, ſhrubby, ſweet Gale, ſweet Willow, Dutch Myrtle, or Gale.*
2. Myrica (*Cerifera*) foliis lanceolatis ſubſerratis, caule arboreſcente. Kalm. *Myrica with ſpear-ſhaped leaves, and a ſhrubby ſtalk.* Myrtus Brabanticæ ſimilis Carolinienſis baccifera, fructu racemoſo ſeſſili monopyreno. Pluk Phyt. tab. 48. fol. 9. *Carolina Myrtle like that of the Dutch, with berries growing in bunches, and ſitting cloſe to the ſtalks, commonly called Candleberry Myrtle.*
3. Myrica (*Carolinienſis*) foliis lanceolatis ſerratis, caule ſuffruticoſa. *Myrica with ſpear-ſhaped ſawed leaves, and a ſhrubby ſtalk.* Myrtus Brabanticæ ſimilis Carolinienſis humilior, foliis latioribus & magis ſerratis. Cateſb. Car. vol. i. p. 13. *Lower Carolina Myrtle, or Candleberry-tree reſembling that of Brabant, having broader leaves which are more ſawed.*
4. Myrica (*Aſplenifolia*) foliis oblongis alternatim ſinuatis. Hort. Cliff. 456. *Myrica with oblong oval leaves, which are alternately ſinuated.* Gale Mariana Aſplenii folio. Pet. Muſ. 773. *Maryland Gale with a Spleenwort leaf.*
5. Myrica (*Quercifolia*) foliis oblongis oppoſitè ſinuatis glabris. *Myrica with oblong ſmooth leaves, which are oppoſitely ſinuated.* Laurus Africana minor, folio quercûs. Hort. Amſt. 2. p. 161. *Smaller African Bay with an Oak leaf.*
6. Myrica (*Hirſuta*) foliis oblongis oppoſitè ſinuatis hirſutis. *Myrica with oblong hairy leaves, which are oppoſitely ſinuated.*
7. Myrica (*Cordifolia*) foliis ſubcordatis ſerratis ſeſſilibus. Hort. Cliff. 456. *Myrica with ſawed leaves which are almoſt heart-ſhaped, and ſit cloſe to the ſtalk.* Gale Capenſis, ilicis cocciferæ foliò. Pet. Muſ. 774. *Gale from the Cape, with a leaf like the Kermes Oak.*

The firſt ſort grows naturally upon bogs in many parts of England, particularly in the northern and weſtern counties, as alſo in Windſor-park, and near Tunbridge-wells. This riſes with many ſhrubby ſtalks near four feet high, which divide into ſeveral ſlender branches, garniſhed with ſtiff ſpear-ſhaped leaves, about an inch and a half long, and half an inch broad in the middle; they are of a light or yellowiſh green, ſmooth, and a little ſawed at their points, and emit a fragrant odour when bruiſed; they are placed alternately on their branches. The male flowers or katkins are produced from the ſide of the branches, growing upon ſeparate plants from the female, which are ſucceeded by cluſters of ſmall berries, each having a ſingle ſeed. It flowers in July, and the ſeeds ripen in autumn.

The leaves of this ſhrub has been by ſome perſons gathered and uſed for Tea, but it is generally ſuppoſed to be hurtful to the brain; but from this uſe of it, a learned phyſician a few years ſince, wrote a treatiſe to prove this to be the true Tea, in which he has only ſhewn his want of knowledge in theſe things.

It grows naturally in bogs, ſo cannot be made to thrive on dry land, for which reaſon it is ſeldom preſerved in gardens.

The ſecond ſort grows naturally in North America, where the inhabitants get a ſort of green wax from the berries, which they make into candles. The method of collecting and preparing this, is deſcribed by Mr. Cateſby, in his Hiſtory of Carolina.

This grows naturally in bogs and ſwampy lands, where it riſes with many ſtrong ſhrubby ſtalks eight or ten feet high, ſending out ſeveral branches, garniſhed with ſtiff ſpear-ſhaped leaves near three inches long, and one broad in the middle; they are ſmooth and entire, having ſcarce any foot-ſtalks, of a yellowiſh lucid green on their upper ſide, but paler on their under, ſtanding alternately, and pretty cloſe to the branches; theſe have a very grateful odour when bruiſed. The katkins come out upon different plants from the berries; theſe are about an inch long, ſtanding erect. The female flowers come out on the ſide of the branches in longiſh bunches, which are ſucceeded by ſmall roundiſh berries, covered with a ſort of meal. This ſhrub delights in a moiſt ſoft ſoil, in which it thrives extremely well, and lives in the open air without any protection.

The third ſort grows naturally in Carolina; this doth not riſe ſo high as the former, the branches are not ſo ſtrong, and they have a grayiſh bark; the leaves are ſhorter, broader, and are ſawed on their edges, but in other reſpects is like the ſecond ſort; the berries of this are alſo collected for the ſame purpoſe.

Theſe ſorts are propagated by ſeeds, which ſhould be ſown in the autumn, and then the plants will come up the following ſpring; but if the ſeeds are kept out of the ground till the ſpring, they ſeldom grow till the year after. Theſe plants will require water in dry weather, and ſhould be ſcreened from froſts while young, but when they have obtained ſtrength, they will reſiſt the cold of this country very well.

The fourth ſort grows naturally in Philadelphia, from whence many of the plants have been brought to England, and thoſe which have been planted on a moiſt ſoil have thriven very well; ſome of theſe creep at their roots, and ſend up ſuckers plentifully, in the ſame manner as in their native ſoil.

This riſes with ſlender ſhrubby ſtalks near three feet high, which are hairy, and divide into ſeveral ſlender branches, which are garniſhed with leaves from three to four inches long, and half an inch broad; they are alternately indented almoſt to the midrib, and have a great reſemblance to thoſe of Spleenwort; they are of a dark green, hairy on their under ſide, and ſit cloſe to the ſtalks. The male flowers or katkins come out on the ſide of the branches between the leaves; theſe are oval, and ſtand erect. I have not ſeen any of theſe plants in fruit, ſo I can give no deſcription of it.

This ſort may be propagated by ſuckers, which are ſent out from the roots when it is planted in a looſe moiſt ſoil, and will endure the cold full as well as the two former ſorts.

The fifth and ſixth ſorts grow naturally at the Cape of Good Hope; theſe only differ from each other, in one having very ſmooth ſhining leaves, and thoſe of the other hairy. I do not know if they are really different ſpecies, but as I received them from Holland as ſuch, and the plants ſtill retaining their difference, ſo I have enumerated them both.

Theſe riſe with ſhrubby ſlender ſtalks about four feet high, which divide into ſmaller branches, which in one ſort are ſmooth, and in the other they are hairy; theſe are cloſely garniſhed with leaves about an inch and a half long, and almoſt an inch broad; ſome having two, others three, deep indentures on their ſides, which are oppoſite; in one ſort they are ſmooth and ſhining, and in the other they are hairy, and of a darker green; they ſit cloſe to the branches, and end in obtuſe points which are indented: between the leaves come out ſome oval katkins, which drop off, ſo that all the plants which I have ſeen have been male, therefore I can give no account of the fruit. Theſe retain their leaves all the year, but are too tender to live through the winter in the open air in England, ſo muſt be placed in the green-houſe in winter. As theſe do not produce ſeeds here, ſo they are propagated by layers, but they do not take root very freely, ſo that the plants are not very common in Europe at preſent; for I do not find that the cuttings of theſe plants will eaſily take root, having made ſeveral trials of them in all the different methods; nor have the Dutch gardeners had better ſucceſs, ſo that the plants are as ſcarce there as in England.

When the layers are laid down, that part of the ſhoot which is laid ſhould be tongued at a joint, as is practiſed in laying of Carnations; and the young ſhoots only ſhould be choſen for this purpoſe, for the old branches will not put out roots. Theſe layers are often two years before they will have taken root enough to tranſplant, for they ſhould not be ſeparated from the old plants till they have made good roots, becauſe they are very ſubject to miſcarry if they are not well rooted.

When they are taken off from the old plants, they ſhould be each put into a ſeparate ſmall pot, filled with ſoft, rich, loamy earth; and if they are placed under a common frame, ſhading them from the ſun in the middle of the day, it will forward their taking new root; then they may be placed in a ſheltered ſituation during the ſummer, and in the autumn removed into the green-houſe, and treated in the ſame way as other plants from the ſame country. The beſt ſeaſon for laying down the branches, I have obſerved to be in July, and by the ſame time the following year they have been fit to remove.

The ſeventh ſort is a native of the Cape of Good Hope; this hath a weak ſhrubby ſtalk which riſes five or ſix feet high, ſending out many long ſlender branches, which are cloſely garniſhed their whole length with ſmall heart-ſhaped leaves, which ſit cloſe to the branches, and are ſlightly indented and waved on their edges. The flowers come out between the leaves in roundiſh bunches; theſe are male in all the the plants I have yet ſeen; they have an uncertain number of ſtamina, and are all included in one common ſcaly involucrum or cover. Theſe flowers appear in July, but make no great appearance; the leaves of this ſort continue all the year green.

This is propagated in the ſame way as the two former ſorts, and is difficult to increaſe, ſo is not common in the European gardens. It requires the ſame treatment as the two former ſorts.

MYRRHIS. See Chærophyllum, Scandix, Siſon.

MYRTUS. Tourn. Inſt. R. H. 640. tab. 409. Lin. Gen. Plant. 543. Myrtle; in French, *Mirte*.

The Characters are,

The empalement of the flower is of one leaf, cut into five acute points at the top, is permanent, and ſits on the germen. The flower has five large oval petals which are inſerted in the empalement, and a great number of ſmall ſtamina which are alſo inſerted in the empalement, terminated by ſmall ſummits. The germen is ſituated under the flower, ſupporting a ſlender ſtyle, crowned by an obtuſe ſtigma. The germen afterward turns to an oval berry with three cells, crowned by the empalement, each cell containing one or two kidney-ſhaped ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's twelfth claſs, in which is contained thoſe plants whoſe flowers have about twenty ſtamina and one ſtyle.

The Species are,

1. Myrtus (*Communis*) foliis ovatis, pedunculis longioribus. *Myrtle with oval leaves, and longer foot-ſtalks to the flowers.* Myrtus latifolia Romana. C. B. P. 468. *Broad-leaved Roman Myrtle, or common broad-leaved Myrtle.*
2. Myrtus (*Belgica*) foliis lanceolatis acuminatis. *Myrtle with ſpear-ſhaped acute-pointed leaves.* Myrtus latifolia Belgica. C. B. P. 469. *Broad-leaved Dutch Myrtle.*
3. Myrtus (*Acuta*) lanceolato-ovatis acutis. *Myrtle with ſpear-ſhaped, oval, acute-pointed leaves.* Myrtus ſylveſtris, foliis acutiſſimis. C. B. P. 469. *Wild Myrtle with very acute-pointed leaves.*
4. Myrtus (*Bœtica*) foliis ovato-lanceolatis confertis. *Myrtle with oval ſpear-ſhaped leaves growing in cluſters.* Myrtus latifolia Bœtica 2 vel foliis laurinus, confertim naſcentibus. C. B. P. 469. *Second broad-leaved Spaniſh Myrtle, with Bay leaves growing in cluſters, commonly called Orange-leaved Myrtle.*
5. Myrtus (*Italica*) foliis ovato-lanceolatis acutis, ramis erectioribus. *Myrtle with oval, acute-pointed, ſpear-ſhaped leaves, and erect branches.* Myrtus communis Italica. C. B. P. 468. *Common Italian Myrtle, called upright Myrtle.*
6. Myrtus (*Tarentina*) foliis ovatis, baccis rotundioribus. *Myrtle with oval leaves and rounder berries.* Myrtus minor vulgaris. C. B. P. 469. *Common ſmaller Myrtle, called the Box-leaved Myrtle.*
7. Myrtus (*Minima*) foliis lineari-lanceolatis acuminatis. *Myrtle with linear, ſpear-ſhaped, acute-pointed leaves.* Myrtus foliis minimis & mucronatis. C. B. P. 469. *Myrtle with the ſmalleſt ſharp-pointed leaves, commonly called Roſemary-leaved Myrtle.*
8. Myrtus (*Zeylanica*) pedunculis multifloris, foliis ovatis ſubpetiolatis. Lin. Sp. Plant. 472. *Myrtle with many flowers on each foot-ſtalk, and oval leaves having ſhort foot-ſtalks.* Myrtus Zeylanica odoratiſſima, baccis niveis monococcis. H. L. 434. *Sweet-ſmelling Myrtle of Ceylon, with ſnow white berries containing one ſeed.*

The firſt ſort is the common broad-leaved Myrtle, which is one of the hardieſt kinds we have. The leaves of this are an inch and a half long, and one inch broad, of a lucid green, ſtanding upon ſhort foot-ſtalks. The flowers are larger than thoſe of the other ſorts, and come out from the ſide of the branches, on pretty long foot-ſtalks; theſe are ſucceeded by oval berries of a dark purple colour, incloſing three or four hard kidney-ſhaped ſeeds. It flowers in July and Auguſt, and the berries ripen in winter. This ſort is by ſome called the flowering Myrtle, becauſe it generally has a greater quantity of flowers, and thoſe are larger than of any other ſort.

The ſecond ſort has leaves much leſs than thoſe of the former, and are more pointed, ſtanding cloſer together on the branches; the midrib on the under ſide of the leaves is of a purple colour, they are of a darker green, and ſit cloſer to the branches. The flowers are ſmaller, and have ſhorter foot-ſtalks than thoſe of the firſt ſort; this flowers a little later in the ſummer, and ſeldom ripens its berries here.

The double flowering Myrtle I take to be a variety of this, for the leaves and growth of the plant, the ſize of the flowers, and the time of flowering, agree better with this than any of the other ſorts.

The third ſort grows naturally in the ſouth of France and in Italy; the leaves of this are much ſmaller than thoſe of the ſecond, being leſs than an inch long, and not more than half an inch broad, of an oval ſpear-ſhape, ending in acute points, of a dull green, and ſet pretty cloſe on the branches. The flowers are ſmaller than either of the former, and come out from the wings of the leaves toward the end of the branches; the berries are ſmall and oval.

The fourth ſort hath a ſtronger ſtalk and branches than either of the former ſorts, and riſes to a greater height; the leaves are oval, ſpear-ſhaped, and are placed in cluſters round the branches; theſe are of a dark green. The flowers are of a middling ſize, and come out ſparingly from between the leaves; the berrries are oval, and ſmaller than thoſe of the firſt ſort, but ſeldom ripens in England. The gardeners call this the Orange-leaved Myrtle, and by ſome it is ſtiled the Bay-leaved Myrtle. This ſort is not ſo hardy as the former.

The fifth ſort is the common Italian Myrtle; this hath oval ſpear-ſhaped leaves, ending in acute points; the branches of this grow more erect than thoſe of either of the former ſorts, as do alſo the leaves, from whence it is called by the gardeners upright Myrtle. The flowers of this ſort are not large, and the petals are marked with purple at their points, while they remain cloſed; the berries are ſmall, oval, and of a purple colour. There is a variety of this with white berries, in which it only differs from this; and I believe the Nutmeg Myrtle is only a variety of this, for I have raiſed ſeveral of the plants from ſeed, many of which were ſo like the Italian Myrtle, as not to be diſtinguiſhed from it.

The ſixth ſort is commonly called the Box-leaved Myrtle; the leaves of this are oval, ſmall, and ſit cloſe on the branches; they are of a lucid green, ending in obtuſe points; the branches are weak, and frequently hang downward, when they are permitted to grow without ſhortening, and have a grayiſh bark. The flowers are ſmall, and come late in the ſummer, the berries are ſmall and round.

The ſeventh ſort is called the Roſemary-leaved Myrtle, and by ſome it is called the Thyme-leaved Myrtle. The branches of this grow pretty erect; the leaves are placed cloſe on the branches; they are ſmall, narrow, and end in acute points; they are of a lucid green, and have a fragrant odour when bruiſed. The flowers of this are ſmall, and come late in the ſeaſon, and are but ſeldom ſucceeded by berries here.

There are ſome other varieties of theſe Myrtles, which are propagated in the gardens for ſale; but as their difference has been occaſioned by culture, ſo it would be multiplying their titles to little purpoſe. Thoſe which are here enumerated I believe to be really diſtinct, for I have raiſed moſt of them from ſeeds, and have not found them change from one to another, though there has been other ſmall variations among the plants.

The eighth ſort is a native of the Iſland of Ceylon: this is much tenderer than either of the former ſorts, ſo cannot be kept through the winter in England, without ſome artificial heat. This hath a ſtrong upright ſtalk, covered with a ſmooth gray bark, dividing upward into many ſlender ſtiff branches, garniſhed with oval leaves placed oppoſite, which are near two inches long, and an inch and a quarter broad, ending in points; they are of a lucid green, and have very ſhort foot-ſtalks. The flowers come out at the ends of the branches, ſeveral of them being ſuſtained upon one common foot-ſtalk, which branches out, and each flower ſtands on a very ſlender diſtinct foot-ſtalk; they are very like the flowers of Italian Myrtle, but always appear in December and January, and are never ſucceeded by berries here.

I ſhall firſt treat of the method of cultivating and propagating the common ſorts of Myrtle, as they all require nearly the ſame management, and ſhall afterward take notice of that of the laſt mentioned, which require a different treatment; but as the varieties of the common ſorts of Myrtle are cultivated in the gardens for ſale, I ſhall juſt mention the titles by which they are known, that the curious may be informed how many there are.

Two ſorts of Nutmeg Myrtles, one with a broader leaf than the other.

The Bird's Neſt Myrtle, the ſtriped Nutmeg Myrtle, the ſtriped upright Myrtle, the ſtriped Roſemary-leaved Myrtle, the ſtriped Box-leaved Myrtle, and the ſtriped broad-leaved Myrtle.

Theſe plants may be all propagated from cuttings, the beſt ſeaſon for which is in the beginning of July, when you ſhould make choice of ſome of the ſtraiteſt and moſt vigorous young ſhoots, which ſhould be about ſix or eight inches long, and the leaves on the lower part muſt be ſtripped off about two or three inches high, and the part twiſted which is to be placed in the ground; then having filled a parcel of pots (in proportion to the quantity of cuttings deſigned) with light rich earth, you ſhould plant the cuttings therein, at about two inches diſtance from each other, obſerving to cloſe the earth faſt about them, and give them ſome water to ſettle it to the cuttings; then place the pots under a common hot-bed frame, plunging them either into ſome old dung, or tanners bark, which will prevent the earth from drying too faſt; but you muſt carefully ſhade them with mats in the heat of the day, and give them air in proportion to the warmth of the ſeaſon, not forgetting to water them every two or three days, as you ſhall find the earth in the pots require it. With this management, in about ſix weeks, the cuttings will be rooted, and begin to ſhoot, when you muſt inure them to the open air by degrees, into which they ſhould be removed towards the latter end of Auguſt, or the beginning of September, placing them in a ſituation where they may be ſheltered from cold winds, in which place they may remain till the middle or latter end of October, when the pots ſhould be removed into the green-houſe, but ſhould be placed in the cooleſt part thereof, that they may have air given to them whenever the weather is mild, for they require only to be protected from ſevere cold, except the Orange-leaved, and the ſtriped Nutmeg Myrtles, which are ſomewhat tenderer than the reſt, and ſhould have a warmer ſituation.

During the winter ſeaſon, they muſt be frequently, but gently watered; and, if any decayed leaves appear, they ſhould be conſtantly picked off, as alſo the pots kept clear from weeds, which, if permitted to grow, will ſoon overſpread the young plants, and deſtroy them.

If theſe pots are placed under a common hot-bed frame in winter, where they may be ſcreened from froſt, and have the free air in mild weather, the young plants will ſucceed better than in a green-houſe, provided they do not receive too much wet, and are not kept cloſely covered, which will occaſion their growing mouldy, and dropping their leaves.

The ſpring following theſe plants ſhould be taken out of the pots very carefully, preſerving a ball of earth to the roots of each of them, and every one ſhould be placed into a ſeparate ſmall pot filled with rich light earth, obſerving to water them well to ſettle the earth to their roots, and place them under a frame until they have taken root; after which they ſhould be inured to the open air, and in May they muſt be placed abroad for the ſummer, in a ſheltered ſituation, where they may be defended from ſtrong winds.

During the ſummer ſeaſon they will require to be plentifully watered, eſpecially being in ſuch ſmall pots, which in that ſeaſon ſoon dry; therefore you ſhould obſerve to place them where they ſhould receive the morning ſun, for when they are too much expoſed to the ſun in the heat of the day, the moiſture contained in the earth of theſe ſmall pots will ſoon be exhaled, and the plants greatly retarded in their growth thereby.

In Auguſt following you ſhould examine your pots, to ſee if the roots of the plants have not made way out through the hole in the bottom of the pots, which if you obſerve, you muſt then ſhift them into pots a ſize larger, filling them up with the like rich earth, and obſerve to trim the roots which were matted to the ſide of the pots, as alſo to looſen the earth from the outſide of the ball with your hands, ſome of which ſhould be taken off, that the roots may the eaſier find paſſage into the freſh earth; then you muſt water them well, and place the pots in a ſituation where they may be defended from ſtrong winds; and at this time you may trim the plants, in order to reduce them to a regular figure; and if they are inclinable to make crooked ſtems, you ſhould thruſt down a ſlender ſtrait ſtick cloſe by them, to which their ſtems ſhould be faſtened, ſo as to bring them upright.

If care be taken to train them thus while they are young, the ſtems afterward, when they have acquired ſtrength, will continue ſtrait without any ſupport, and their branches may be pruned, ſo as to form either balls or pyramids, which for ſuch plants as are preſerved in the green-houſe, and require to be kept in ſmall compaſs, is the beſt method to have them handſome; but then theſe ſheered plants will not produce any flowers, for which reaſon that ſort with double flowers ſhould not be clipped, becauſe the chief beauty of that conſiſts in its flowers; but it will be neceſſary to ſuffer a plant or two of each kind to grow rude, for the uſe of their branches in noſegays, &c. for it will greatly deface thoſe which have been conſtantly ſheered to cut off their branches.

As theſe plants advance in ſtature, they ſhould annually be removed into larger pots, acording to the ſize of their roots; but you muſt be careful not to put them into pots too large, which will cauſe them to ſhoot weak, and many times prove the deſtruction of them; therefore when they are taken out of the former pots, the earth about their roots ſhould be pared off, and that within ſide the ball muſt be gently looſened, that the roots may not be too cloſely confined; and then place them into the ſame pots again, provided they are not too ſmall, filling up the ſides and bottom of them with freſh rich earth, and giving them plenty of water to ſettle the earth to their roots; which ſhould be frequently repeated, for they require to be often watered both in winter and ſummer, but in hot weather they muſt have it in plenty.

The beſt ſeaſon for ſhifting theſe plants is either in April or Auguſt, for if it be done much ſooner in the ſpring, the plants are then in a ſlow growing ſtate, and ſo not capable to ſtrike out freſh roots again very ſoon; and if it be done later in autumn, the cold weather coming on will prevent their taking root; nor is it adviſeable to do it in the great heat of ſummer, becauſe they will require to be very often watered, and alſo to be placed in the ſhade, otherwiſe they will be liable to droop for a conſiderable time; and that being the ſeaſon when theſe plants ſhould be placed amongſt other exotics, to adorn the ſeveral parts of the garden, theſe plants, being then removed, ſhould not be expoſed until they have taken root again, which, at that time (if the ſeaſon be hot and dry) will be three weeks or a month.

In October, when the nights begin to be froſty, you ſhould remove the plants into the green-houſe; but if the weather proves favourable in autumn (as it often happens) they may remain abroad until the beginning of November; for if they are carried into the green-houſe too ſoon, and the autumn ſhould prove warm, they will make freſh ſhoots at that ſeaſon, which will be weak, and often grow mouldy in winter, if the weather ſhould be ſo ſevere as to require the windows to be kept cloſely ſhut, whereby they will be greatly defaced; for which reaſon they ſhould always be kept as long abroad as the ſeaſon will permit, and removed out again in the ſpring before they ſhoot out; and during the winter ſeaſon that they are in the green-houſe, they ſhould have as much free air as poſſible when the weather is mild.

The three firſt-mentioned ſorts I have ſeen planted abroad in warm ſituations, and upon a dry ſoil, where they have endured the cold of our winters for ſeveral years very well, with only being covered in very hard froſts with two or three mats, and the ſurface of the ground about their roots covered with a little mulch to prevent the froſt from entering the ground; but in Cornwall and Devonſhire, where the winters are more favourable than in moſt other parts of England, there are large hedges of Myrtle which have been planted ſeveral years, and are very thriving and vigorous, ſome of which are upward of ſix feet high; and I believe, if the double flowering kind were planted abroad, it would endure the cold as well as any of the other ſorts, it being a native of the ſouthern parts of France. This, and the Orange-leaved kind, are the moſt difficult to take root from cuttings; but if they are planted toward the latter end of June, making choice of only ſuch ſhoots as are tender, and the pots are plunged into an old bed of tanners bark which has loſt moſt of its heat, and the glaſſes ſhaded every day, they will take root extremely well, as I have more than once experienced. The Orange-leaved ſort, and thoſe with variegated leaves, are ſomewhat tenderer than the ordinary ſorts, and ſhould be houſed a little ſooner in autumn, and placed farther from the windows of the green-houſe.

The eighth ſort is at preſent rare in Europe, ſo is in very few gardens. This ſort was by Dr. Linnæus ſeparated from the Myrtles in the former editions of his works, and had the title of Myrſine applied to it; but in his Species of Plants, he has joined it to that genus again, to which, according to his ſyſtem, it properly belongs; for the number of petals, ſtamina, and ſtyle, do agree with thoſe of the Myrtle, but it differs in fructification, this having but one ſeed in each fruit, and the Myrtle has four or five.

This plant is with difficulty propagated, which occaſions its preſent ſcarcity, for as it does not produce ripe ſeeds in Europe, it can only be increaſed by layers or cuttings. By the former method the layers are commonly two years before they take root, and the cuttings frequently fail, though the latter is preferred, when performed at a proper ſeaſon and in a right method; the beſt time to plant the cuttings is in May: in the choice of them, it ſhould be the ſhoots of the former year, with a ſmall piece of the two years wood at bottom; theſe ſhould be planted in ſmall pots, filled with ſoft loamy earth, for ſmall pots are to be preferred to large ones for this purpoſe, and they ſhould be plunged into a very moderate hot-bed of tanners bark; and if the pots are each covered with ſmall bell or hand-glaſſes, ſuch as have been uſed for blowing of Carnations to exclude the air, it will be of great ſervice to promote the cuttings putting out roots, though they are covered with the glaſſes of the hot-bed above them; the cuttings ſhould be ſhaded from the ſun in the heat of the day, and gently refreſhed with water, as the earth in the pots is found to dry, but they ſhould by no means have too much wet; thoſe cuttings which ſucceed, will have taken root by July, when they ſhould be gradually inured to bear the open air, into which it will be proper to remove them about the middle of that month, that they may be ſtrengthened before winter, but it will not be proper to tranſplant the cuttings till ſpring; the pots muſt be removed into a temperate ſtove in autumn, and during the winter the cuttings muſt be gently refreſhed with water. In the ſpring they ſhould be carefully taken up, and each planted in a ſmall pot filled with light earth from a kitchen-garden, and plunged into a moderate hot-bed to forward their taking freſh root; then they ſhould be gradually hardened, and in July placed in the open air in a ſheltered ſituation, where they may remain till the end of September, and then be removed into the ſtove.

This plant will not live through the winter in England in a green-houſe, but if it is placed in a moderate degree of warmth, it will flower well in winter; and in July, Auguſt, and September, the plants ſhould be placed abroad in a ſheltered ſituation.

MYRTUS BRABANTICA. See MYRICA.
